In most cases, no additional code is needed to make instances picklable. By default, pickle will retrieve the class and the attributes of an instance via introspection. When a class instance is unpickled, its `__init__()` method is usually *not* invoked. The default behaviour first creates an uninitialized instance and then restores the saved attributes. The following code shows an implementation of this behaviour:

[2] This is why `lambda` functions cannot be pickled: all `lambda` functions share the same name: `<lambda>`.
[3] The exception raised will likely be an *ImportError* or an *AttributeError* but it could be something else.

```
def save(obj):
    return (obj.__class__, obj.__dict__)

def load(cls, attributes):
    obj = cls.__new__(cls)
    obj.__dict__.update(attributes)
    return obj
```

Classes can alter the default behaviour by providing one or several special methods:

`object.__getnewargs_ex__()`
: In protocols 2 and newer, classes that implements the *__getnewargs_ex__()* method can dictate the values passed to the `__new__()` method upon unpickling. The method must return a pair `(args, kwargs)` where *args* is a tuple of positional arguments and *kwargs* a dictionary of named arguments for constructing the object. Those will be passed to the `__new__()` method upon unpickling.

  You should implement this method if the `__new__()` method of your class requires keyword-only arguments. Otherwise, it is recommended for compatibility to implement *__getnewargs__()*.

  Changed in version 3.6: *__getnewargs_ex__()* is now used in protocols 2 and 3.

`object.__getnewargs__()`
: This method serves a similar purpose as *__getnewargs_ex__()*, but supports only positional arguments. It must return a tuple of arguments `args` which will be passed to the `__new__()` method upon unpickling.

  __getnewargs__() will not be called if *__getnewargs_ex__()* is defined.

  Changed in version 3.6: Before Python 3.6, *__getnewargs__()* was called instead of *__getnewargs_ex__()* in protocols 2 and 3.

`object.__getstate__()`
: Classes can further influence how their instances are pickled; if the class defines the method *__getstate__()*, it is called and the returned object is pickled as the contents for the instance, instead of the contents of the instance's dictionary. If the *__getstate__()* method is absent, the instance's *__dict__* is pickled as usual.

`object.__setstate__(`*state*`)`
: Upon unpickling, if the class defines *__setstate__()*, it is called with the unpickled state. In that case, there is no requirement for the state object to be a dictionary. Otherwise, the pickled state must be a dictionary and its items are assigned to the new instance's dictionary.

  Note: If *__getstate__()* returns a false value, the *__setstate__()* method will not be called upon unpickling.

Refer to the section *Handling Stateful Objects* for more information about how to use the methods *__getstate__()* and *__setstate__()*.

Note: At unpickling time, some methods like `__getattr__()`, `__getattribute__()`, or `__setattr__()` may be called upon the instance. In case those methods rely on some internal invariant being true, the type should implement *__getnewargs__()* or *__getnewargs_ex__()* to establish such an invariant; otherwise, neither `__new__()` nor `__init__()` will be called.

As we shall see, pickle does not use directly the methods described above. In fact, these methods are part of the copy protocol which implements the *__reduce__()* special method. The copy protocol provides a unified interface for retrieving the data necessary for pickling and copying objects.[4]

[4] The *copy* module uses this protocol for shallow and deep copying operations.

Although powerful, implementing *__reduce__()* directly in your classes is error prone. For this reason, class designers should use the high-level interface (i.e., *__getnewargs_ex__()*, *__getstate__()* and *__setstate__()*) whenever possible. We will show, however, cases where using *__reduce__()* is the only option or leads to more efficient pickling or both.

`object.__reduce__()`

The interface is currently defined as follows. The *__reduce__()* method takes no argument and shall return either a string or preferably a tuple (the returned object is often referred to as the "reduce value").

If a string is returned, the string should be interpreted as the name of a global variable. It should be the object's local name relative to its module; the pickle module searches the module namespace to determine the object's module. This behaviour is typically useful for singletons.

When a tuple is returned, it must be between two and five items long. Optional items can either be omitted, or `None` can be provided as their value. The semantics of each item are in order:

- A callable object that will be called to create the initial version of the object.
- A tuple of arguments for the callable object. An empty tuple must be given if the callable does not accept any argument.
- Optionally, the object's state, which will be passed to the object's *__setstate__()* method as previously described. If the object has no such method then, the value must be a dictionary and it will be added to the object's *__dict__* attribute.
- Optionally, an iterator (and not a sequence) yielding successive items. These items will be appended to the object either using `obj.append(item)` or, in batch, using `obj.extend(list_of_items)`. This is primarily used for list subclasses, but may be used by other classes as long as they have `append()` and `extend()` methods with the appropriate signature. (Whether `append()` or `extend()` is used depends on which pickle protocol version is used as well as the number of items to append, so both must be supported.)
- Optionally, an iterator (not a sequence) yielding successive key-value pairs. These items will be stored to the object using `obj[key] = value`. This is primarily used for dictionary subclasses, but may be used by other classes as long as they implement `__setitem__()`.

`object.__reduce_ex__`(*protocol*)

Alternatively, a *__reduce_ex__()* method may be defined. The only difference is this method should take a single integer argument, the protocol version. When defined, pickle will prefer it over the *__reduce__()* method. In addition, *__reduce__()* automatically becomes a synonym for the extended version. The main use for this method is to provide backwards-compatible reduce values for older Python releases.

Persistence of External Objects

For the benefit of object persistence, the *pickle* module supports the notion of a reference to an object outside the pickled data stream. Such objects are referenced by a persistent ID, which should be either a string of alphanumeric characters (for protocol 0)[5] or just an arbitrary object (for any newer protocol).

The resolution of such persistent IDs is not defined by the *pickle* module; it will delegate this resolution to the user defined methods on the pickler and unpickler, *persistent_id()* and *persistent_load()* respectively.

To pickle objects that have an external persistent id, the pickler must have a custom *persistent_id()* method that takes an object as an argument and returns either `None` or the persistent id for that object. When `None` is returned, the pickler simply pickles the object as normal. When a persistent ID string is

[5] The limitation on alphanumeric characters is due to the fact the persistent IDs, in protocol 0, are delimited by the newline character. Therefore if any kind of newline characters occurs in persistent IDs, the resulting pickle will become unreadable.

returned, the pickler will pickle that object, along with a marker so that the unpickler will recognize it as a persistent ID.

To unpickle external objects, the unpickler must have a custom *persistent_load()* method that takes a persistent ID object and returns the referenced object.

Here is a comprehensive example presenting how persistent ID can be used to pickle external objects by reference.

```
# Simple example presenting how persistent ID can be used to pickle
# external objects by reference.

import pickle
import sqlite3
from collections import namedtuple

# Simple class representing a record in our database.
MemoRecord = namedtuple("MemoRecord", "key, task")

class DBPickler(pickle.Pickler):

    def persistent_id(self, obj):
        # Instead of pickling MemoRecord as a regular class instance, we emit a
        # persistent ID.
        if isinstance(obj, MemoRecord):
            # Here, our persistent ID is simply a tuple, containing a tag and a
            # key, which refers to a specific record in the database.
            return ("MemoRecord", obj.key)
        else:
            # If obj does not have a persistent ID, return None. This means obj
            # needs to be pickled as usual.
            return None

class DBUnpickler(pickle.Unpickler):

    def __init__(self, file, connection):
        super().__init__(file)
        self.connection = connection

    def persistent_load(self, pid):
        # This method is invoked whenever a persistent ID is encountered.
        # Here, pid is the tuple returned by DBPickler.
        cursor = self.connection.cursor()
        type_tag, key_id = pid
        if type_tag == "MemoRecord":
            # Fetch the referenced record from the database and return it.
            cursor.execute("SELECT * FROM memos WHERE key=?", (str(key_id),))
            key, task = cursor.fetchone()
            return MemoRecord(key, task)
        else:
            # Always raises an error if you cannot return the correct object.
            # Otherwise, the unpickler will think None is the object referenced
            # by the persistent ID.
            raise pickle.UnpicklingError("unsupported persistent object")

def main():
    import io
```

(continues on next page)

(continued from previous page)

```
    import pprint

    # Initialize and populate our database.
    conn = sqlite3.connect(":memory:")
    cursor = conn.cursor()
    cursor.execute("CREATE TABLE memos(key INTEGER PRIMARY KEY, task TEXT)")
    tasks = (
        'give food to fish',
        'prepare group meeting',
        'fight with a zebra',
        )
    for task in tasks:
        cursor.execute("INSERT INTO memos VALUES(NULL, ?)", (task,))

    # Fetch the records to be pickled.
    cursor.execute("SELECT * FROM memos")
    memos = [MemoRecord(key, task) for key, task in cursor]
    # Save the records using our custom DBPickler.
    file = io.BytesIO()
    DBPickler(file).dump(memos)

    print("Pickled records:")
    pprint.pprint(memos)

    # Update a record, just for good measure.
    cursor.execute("UPDATE memos SET task='learn italian' WHERE key=1")

    # Load the records from the pickle data stream.
    file.seek(0)
    memos = DBUnpickler(file, conn).load()

    print("Unpickled records:")
    pprint.pprint(memos)

if __name__ == '__main__':
    main()
```

Dispatch Tables

If one wants to customize pickling of some classes without disturbing any other code which depends on pickling, then one can create a pickler with a private dispatch table.

The global dispatch table managed by the *copyreg* module is available as `copyreg.dispatch_table`. Therefore, one may choose to use a modified copy of `copyreg.dispatch_table` as a private dispatch table.

For example

```
f = io.BytesIO()
p = pickle.Pickler(f)
p.dispatch_table = copyreg.dispatch_table.copy()
p.dispatch_table[SomeClass] = reduce_SomeClass
```

creates an instance of *pickle.Pickler* with a private dispatch table which handles the `SomeClass` class specially. Alternatively, the code

```
class MyPickler(pickle.Pickler):
    dispatch_table = copyreg.dispatch_table.copy()
    dispatch_table[SomeClass] = reduce_SomeClass
f = io.BytesIO()
p = MyPickler(f)
```

does the same, but all instances of `MyPickler` will by default share the same dispatch table. The equivalent code using the *copyreg* module is

```
copyreg.pickle(SomeClass, reduce_SomeClass)
f = io.BytesIO()
p = pickle.Pickler(f)
```

Handling Stateful Objects

Here's an example that shows how to modify pickling behavior for a class. The `TextReader` class opens a text file, and returns the line number and line contents each time its `readline()` method is called. If a `TextReader` instance is pickled, all attributes *except* the file object member are saved. When the instance is unpickled, the file is reopened, and reading resumes from the last location. The *__setstate__()* and *__getstate__()* methods are used to implement this behavior.

```
class TextReader:
    """Print and number lines in a text file."""

    def __init__(self, filename):
        self.filename = filename
        self.file = open(filename)
        self.lineno = 0

    def readline(self):
        self.lineno += 1
        line = self.file.readline()
        if not line:
            return None
        if line.endswith('\n'):
            line = line[:-1]
        return "%i: %s" % (self.lineno, line)

    def __getstate__(self):
        # Copy the object's state from self.__dict__ which contains
        # all our instance attributes. Always use the dict.copy()
        # method to avoid modifying the original state.
        state = self.__dict__.copy()
        # Remove the unpicklable entries.
        del state['file']
        return state

    def __setstate__(self, state):
        # Restore instance attributes (i.e., filename and lineno).
        self.__dict__.update(state)
        # Restore the previously opened file's state. To do so, we need to
        # reopen it and read from it until the line count is restored.
        file = open(self.filename)
        for _ in range(self.lineno):
            file.readline()
```

(continues on next page)

(continued from previous page)

```
        # Finally, save the file.
        self.file = file
```

A sample usage might be something like this:

```
>>> reader = TextReader("hello.txt")
>>> reader.readline()
'1: Hello world!'
>>> reader.readline()
'2: I am line number two.'
>>> new_reader = pickle.loads(pickle.dumps(reader))
>>> new_reader.readline()
'3: Goodbye!'
```

12.1.6 Restricting Globals

By default, unpickling will import any class or function that it finds in the pickle data. For many applications, this behaviour is unacceptable as it permits the unpickler to import and invoke arbitrary code. Just consider what this hand-crafted pickle data stream does when loaded:

```
>>> import pickle
>>> pickle.loads(b"cos\nsystem\n(S'echo hello world'\ntR.")
hello world
0
```

In this example, the unpickler imports the *os.system()* function and then apply the string argument "echo hello world". Although this example is inoffensive, it is not difficult to imagine one that could damage your system.

For this reason, you may want to control what gets unpickled by customizing *Unpickler.find_class()*. Unlike its name suggests, *Unpickler.find_class()* is called whenever a global (i.e., a class or a function) is requested. Thus it is possible to either completely forbid globals or restrict them to a safe subset.

Here is an example of an unpickler allowing only few safe classes from the *builtins* module to be loaded:

```
import builtins
import io
import pickle

safe_builtins = {
    'range',
    'complex',
    'set',
    'frozenset',
    'slice',
}

class RestrictedUnpickler(pickle.Unpickler):

    def find_class(self, module, name):
        # Only allow safe classes from builtins.
        if module == "builtins" and name in safe_builtins:
            return getattr(builtins, name)
        # Forbid everything else.
        raise pickle.UnpicklingError("global '%s.%s' is forbidden" %
```

(continues on next page)

(continued from previous page)

```
                                    (module, name))

def restricted_loads(s):
    """Helper function analogous to pickle.loads()."""
    return RestrictedUnpickler(io.BytesIO(s)).load()
```

A sample usage of our unpickler working has intended:

```
>>> restricted_loads(pickle.dumps([1, 2, range(15)]))
[1, 2, range(0, 15)]
>>> restricted_loads(b"cos\nsystem\n(S'echo hello world'\ntR.")
Traceback (most recent call last):
  ...
pickle.UnpicklingError: global 'os.system' is forbidden
>>> restricted_loads(b'cbuiltins\neval\n'
...                  b'(S\'getattr(__import__("os"), "system")'
...                  b'("echo hello world")\'\ntR.')
Traceback (most recent call last):
  ...
pickle.UnpicklingError: global 'builtins.eval' is forbidden
```

As our examples shows, you have to be careful with what you allow to be unpickled. Therefore if security is a concern, you may want to consider alternatives such as the marshalling API in *xmlrpc.client* or third-party solutions.

12.1.7 Performance

Recent versions of the pickle protocol (from protocol 2 and upwards) feature efficient binary encodings for several common features and built-in types. Also, the *pickle* module has a transparent optimizer written in C.

12.1.8 Examples

For the simplest code, use the *dump()* and *load()* functions.

```
import pickle

# An arbitrary collection of objects supported by pickle.
data = {
    'a': [1, 2.0, 3, 4+6j],
    'b': ("character string", b"byte string"),
    'c': {None, True, False}
}

with open('data.pickle', 'wb') as f:
    # Pickle the 'data' dictionary using the highest protocol available.
    pickle.dump(data, f, pickle.HIGHEST_PROTOCOL)
```

The following example reads the resulting pickled data.

```
import pickle

with open('data.pickle', 'rb') as f:
    # The protocol version used is detected automatically, so we do not
```

(continues on next page)

(continued from previous page)

```
    # have to specify it.
    data = pickle.load(f)
```

Module *marshal* High-performance serialization of built-in types.

12.2 copyreg — Register pickle support functions

Source code: Lib/copyreg.py

The *copyreg* module offers a way to define functions used while pickling specific objects. The *pickle* and *copy* modules use those functions when pickling/copying those objects. The module provides configuration information about object constructors which are not classes. Such constructors may be factory functions or class instances.

copyreg.**constructor**(*object*)
: Declares *object* to be a valid constructor. If *object* is not callable (and hence not valid as a constructor), raises *TypeError*.

copyreg.**pickle**(*type*, *function*, *constructor=None*)
: Declares that *function* should be used as a "reduction" function for objects of type *type*. *function* should return either a string or a tuple containing two or three elements.

  The optional *constructor* parameter, if provided, is a callable object which can be used to reconstruct the object when called with the tuple of arguments returned by *function* at pickling time. *TypeError* will be raised if *object* is a class or *constructor* is not callable.

  See the *pickle* module for more details on the interface expected of *function* and *constructor*. Note that the *dispatch_table* attribute of a pickler object or subclass of *pickle.Pickler* can also be used for declaring reduction functions.

12.2.1 Example

The example below would like to show how to register a pickle function and how it will be used:

```
>>> import copyreg, copy, pickle
>>> class C(object):
...     def __init__(self, a):
...         self.a = a
...
>>> def pickle_c(c):
...     print("pickling a C instance...")
...     return C, (c.a,)
...
>>> copyreg.pickle(C, pickle_c)
>>> c = C(1)
```

(continues on next page)

(continued from previous page)

```
>>> d = copy.copy(c)
pickling a C instance...
>>> p = pickle.dumps(c)
pickling a C instance...
```

12.3 shelve — Python object persistence

Source code: Lib/shelve.py

A "shelf" is a persistent, dictionary-like object. The difference with "dbm" databases is that the values (not the keys!) in a shelf can be essentially arbitrary Python objects — anything that the *pickle* module can handle. This includes most class instances, recursive data types, and objects containing lots of shared sub-objects. The keys are ordinary strings.

shelve.open(*filename*, *flag='c'*, *protocol=None*, *writeback=False*)

Open a persistent dictionary. The filename specified is the base filename for the underlying database. As a side-effect, an extension may be added to the filename and more than one file may be created. By default, the underlying database file is opened for reading and writing. The optional *flag* parameter has the same interpretation as the *flag* parameter of *dbm.open()*.

By default, version 3 pickles are used to serialize values. The version of the pickle protocol can be specified with the *protocol* parameter.

Because of Python semantics, a shelf cannot know when a mutable persistent-dictionary entry is modified. By default modified objects are written *only* when assigned to the shelf (see *Example*). If the optional *writeback* parameter is set to `True`, all entries accessed are also cached in memory, and written back on *sync()* and *close()*; this can make it handier to mutate mutable entries in the persistent dictionary, but, if many entries are accessed, it can consume vast amounts of memory for the cache, and it can make the close operation very slow since all accessed entries are written back (there is no way to determine which accessed entries are mutable, nor which ones were actually mutated).

Note: Do not rely on the shelf being closed automatically; always call *close()* explicitly when you don't need it any more, or use *shelve.open()* as a context manager:

```
with shelve.open('spam') as db:
    db['eggs'] = 'eggs'
```

Warning: Because the *shelve* module is backed by *pickle*, it is insecure to load a shelf from an untrusted source. Like with pickle, loading a shelf can execute arbitrary code.

Shelf objects support all methods supported by dictionaries. This eases the transition from dictionary based scripts to those requiring persistent storage.

Two additional methods are supported:

Shelf.sync()

Write back all entries in the cache if the shelf was opened with *writeback* set to *True*. Also empty the cache and synchronize the persistent dictionary on disk, if feasible. This is called automatically when the shelf is closed with *close()*.

`Shelf.close()`
Synchronize and close the persistent *dict* object. Operations on a closed shelf will fail with a *ValueError*.

See also:

Persistent dictionary recipe with widely supported storage formats and having the speed of native dictionaries.

12.3.1 Restrictions

- The choice of which database package will be used (such as *dbm.ndbm* or *dbm.gnu*) depends on which interface is available. Therefore it is not safe to open the database directly using *dbm*. The database is also (unfortunately) subject to the limitations of *dbm*, if it is used — this means that (the pickled representation of) the objects stored in the database should be fairly small, and in rare cases key collisions may cause the database to refuse updates.
- The *shelve* module does not support *concurrent* read/write access to shelved objects. (Multiple simultaneous read accesses are safe.) When a program has a shelf open for writing, no other program should have it open for reading or writing. Unix file locking can be used to solve this, but this differs across Unix versions and requires knowledge about the database implementation used.

`class shelve.Shelf(`*dict*, *protocol=None*, *writeback=False*, *keyencoding='utf-8'*`)`
A subclass of *collections.abc.MutableMapping* which stores pickled values in the *dict* object.

By default, version 3 pickles are used to serialize values. The version of the pickle protocol can be specified with the *protocol* parameter. See the *pickle* documentation for a discussion of the pickle protocols.

If the *writeback* parameter is `True`, the object will hold a cache of all entries accessed and write them back to the *dict* at sync and close times. This allows natural operations on mutable entries, but can consume much more memory and make sync and close take a long time.

The *keyencoding* parameter is the encoding used to encode keys before they are used with the underlying dict.

A *Shelf* object can also be used as a context manager, in which case it will be automatically closed when the `with` block ends.

Changed in version 3.2: Added the *keyencoding* parameter; previously, keys were always encoded in UTF-8.

Changed in version 3.4: Added context manager support.

`class shelve.BsdDbShelf(`*dict*, *protocol=None*, *writeback=False*, *keyencoding='utf-8'*`)`
A subclass of *Shelf* which exposes `first()`, `next()`, `previous()`, `last()` and `set_location()` which are available in the third-party `bsddb` module from pybsddb but not in other database modules. The *dict* object passed to the constructor must support those methods. This is generally accomplished by calling one of `bsddb.hashopen()`, `bsddb.btopen()` or `bsddb.rnopen()`. The optional *protocol*, *writeback*, and *keyencoding* parameters have the same interpretation as for the *Shelf* class.

`class shelve.DbfilenameShelf(`*filename*, *flag='c'*, *protocol=None*, *writeback=False*`)`
A subclass of *Shelf* which accepts a *filename* instead of a dict-like object. The underlying file will be opened using *dbm.open()*. By default, the file will be created and opened for both read and write. The optional *flag* parameter has the same interpretation as for the *open()* function. The optional *protocol* and *writeback* parameters have the same interpretation as for the *Shelf* class.

12.3.2 Example

To summarize the interface (`key` is a string, `data` is an arbitrary object):

```
import shelve

d = shelve.open(filename)  # open -- file may get suffix added by low-level
                           # library

d[key] = data              # store data at key (overwrites old data if
                           # using an existing key)
data = d[key]              # retrieve a COPY of data at key (raise KeyError
                           # if no such key)
del d[key]                 # delete data stored at key (raises KeyError
                           # if no such key)

flag = key in d            # true if the key exists
klist = list(d.keys())     # a list of all existing keys (slow!)

# as d was opened WITHOUT writeback=True, beware:
d['xx'] = [0, 1, 2]        # this works as expected, but...
d['xx'].append(3)          # *this doesn't!* -- d['xx'] is STILL [0, 1, 2]!

# having opened d without writeback=True, you need to code carefully:
temp = d['xx']             # extracts the copy
temp.append(5)             # mutates the copy
d['xx'] = temp             # stores the copy right back, to persist it

# or, d=shelve.open(filename,writeback=True) would let you just code
# d['xx'].append(5) and have it work as expected, BUT it would also
# consume more memory and make the d.close() operation slower.

d.close()                  # close it
```

See also:

Module *dbm* Generic interface to `dbm`-style databases.

Module *pickle* Object serialization used by *shelve*.

12.4 `marshal` — Internal Python object serialization

This module contains functions that can read and write Python values in a binary format. The format is specific to Python, but independent of machine architecture issues (e.g., you can write a Python value to a file on a PC, transport the file to a Sun, and read it back there). Details of the format are undocumented on purpose; it may change between Python versions (although it rarely does).[1]

This is not a general "persistence" module. For general persistence and transfer of Python objects through RPC calls, see the modules *pickle* and *shelve*. The *marshal* module exists mainly to support reading and writing the "pseudo-compiled" code for Python modules of `.pyc` files. Therefore, the Python maintainers reserve the right to modify the marshal format in backward incompatible ways should the need arise. If you're serializing and de-serializing Python objects, use the *pickle* module instead – the performance is

[1] The name of this module stems from a bit of terminology used by the designers of Modula-3 (amongst others), who use the term "marshalling" for shipping of data around in a self-contained form. Strictly speaking, "to marshal" means to convert some data from internal to external form (in an RPC buffer for instance) and "unmarshalling" for the reverse process.

comparable, version independence is guaranteed, and pickle supports a substantially wider range of objects than marshal.

Warning: The *marshal* module is not intended to be secure against erroneous or maliciously constructed data. Never unmarshal data received from an untrusted or unauthenticated source.

Not all Python object types are supported; in general, only objects whose value is independent from a particular invocation of Python can be written and read by this module. The following types are supported: booleans, integers, floating point numbers, complex numbers, strings, bytes, bytearrays, tuples, lists, sets, frozensets, dictionaries, and code objects, where it should be understood that tuples, lists, sets, frozensets and dictionaries are only supported as long as the values contained therein are themselves supported. The singletons *None*, *Ellipsis* and *StopIteration* can also be marshalled and unmarshalled. For format *version* lower than 3, recursive lists, sets and dictionaries cannot be written (see below).

There are functions that read/write files as well as functions operating on bytes-like objects.

The module defines these functions:

`marshal.dump`(*value*, *file*[, *version*])
Write the value on the open file. The value must be a supported type. The file must be a writeable *binary file*.

If the value has (or contains an object that has) an unsupported type, a *ValueError* exception is raised — but garbage data will also be written to the file. The object will not be properly read back by *load()*.

The *version* argument indicates the data format that `dump` should use (see below).

`marshal.load`(*file*)
Read one value from the open file and return it. If no valid value is read (e.g. because the data has a different Python version's incompatible marshal format), raise *EOFError*, *ValueError* or *TypeError*. The file must be a readable *binary file*.

Note: If an object containing an unsupported type was marshalled with *dump()*, *load()* will substitute `None` for the unmarshallable type.

`marshal.dumps`(*value*[, *version*])
Return the bytes object that would be written to a file by `dump(value, file)`. The value must be a supported type. Raise a *ValueError* exception if value has (or contains an object that has) an unsupported type.

The *version* argument indicates the data format that `dumps` should use (see below).

`marshal.loads`(*bytes*)
Convert the *bytes-like object* to a value. If no valid value is found, raise *EOFError*, *ValueError* or *TypeError*. Extra bytes in the input are ignored.

In addition, the following constants are defined:

`marshal.version`
Indicates the format that the module uses. Version 0 is the historical format, version 1 shares interned strings and version 2 uses a binary format for floating point numbers. Version 3 adds support for object instancing and recursion. The current version is 4.

12.5 dbm — Interfaces to Unix "databases"

Source code: Lib/dbm/__init__.py

---

dbm is a generic interface to variants of the DBM database — *dbm.gnu* or *dbm.ndbm*. If none of these modules is installed, the slow-but-simple implementation in module *dbm.dumb* will be used. There is a third party interface to the Oracle Berkeley DB.

exception dbm.error

A tuple containing the exceptions that can be raised by each of the supported modules, with a unique exception also named *dbm.error* as the first item — the latter is used when *dbm.error* is raised.

dbm.whichdb(*filename*)

This function attempts to guess which of the several simple database modules available — *dbm.gnu*, *dbm.ndbm* or *dbm.dumb* — should be used to open a given file.

Returns one of the following values: `None` if the file can't be opened because it's unreadable or doesn't exist; the empty string (`''`) if the file's format can't be guessed; or a string containing the required module name, such as `'dbm.ndbm'` or `'dbm.gnu'`.

dbm.open(*file*, *flag='r'*, *mode=0o666*)

Open the database file *file* and return a corresponding object.

If the database file already exists, the *whichdb()* function is used to determine its type and the appropriate module is used; if it does not exist, the first module listed above that can be imported is used.

The optional *flag* argument can be:

Value	Meaning
`'r'`	Open existing database for reading only (default)
`'w'`	Open existing database for reading and writing
`'c'`	Open database for reading and writing, creating it if it doesn't exist
`'n'`	Always create a new, empty database, open for reading and writing

The optional *mode* argument is the Unix mode of the file, used only when the database has to be created. It defaults to octal `0o666` (and will be modified by the prevailing umask).

The object returned by *open()* supports the same basic functionality as dictionaries; keys and their corresponding values can be stored, retrieved, and deleted, and the `in` operator and the `keys()` method are available, as well as `get()` and `setdefault()`.

Changed in version 3.2: `get()` and `setdefault()` are now available in all database modules.

Key and values are always stored as bytes. This means that when strings are used they are implicitly converted to the default encoding before being stored.

These objects also support being used in a `with` statement, which will automatically close them when done.

Changed in version 3.4: Added native support for the context management protocol to the objects returned by *open()*.

The following example records some hostnames and a corresponding title, and then prints out the contents of the database:

```
import dbm

# Open database, creating it if necessary.
```

(continues on next page)

(continued from previous page)

```
with dbm.open('cache', 'c') as db:

    # Record some values
    db[b'hello'] = b'there'
    db['www.python.org'] = 'Python Website'
    db['www.cnn.com'] = 'Cable News Network'

    # Note that the keys are considered bytes now.
    assert db[b'www.python.org'] == b'Python Website'
    # Notice how the value is now in bytes.
    assert db['www.cnn.com'] == b'Cable News Network'

    # Often-used methods of the dict interface work too.
    print(db.get('python.org', b'not present'))

    # Storing a non-string key or value will raise an exception (most
    # likely a TypeError).
    db['www.yahoo.com'] = 4

# db is automatically closed when leaving the with statement.
```

See also:

Module *shelve* Persistence module which stores non-string data.

The individual submodules are described in the following sections.

12.5.1 dbm.gnu — GNU's reinterpretation of dbm

Source code: Lib/dbm/gnu.py

This module is quite similar to the *dbm* module, but uses the GNU library `gdbm` instead to provide some additional functionality. Please note that the file formats created by *dbm.gnu* and *dbm.ndbm* are incompatible.

The *dbm.gnu* module provides an interface to the GNU DBM library. `dbm.gnu.gdbm` objects behave like mappings (dictionaries), except that keys and values are always converted to bytes before storing. Printing a `gdbm` object doesn't print the keys and values, and the `items()` and `values()` methods are not supported.

exception dbm.gnu.error

Raised on *dbm.gnu*-specific errors, such as I/O errors. *KeyError* is raised for general mapping errors like specifying an incorrect key.

dbm.gnu.open(*filename*[, *flag*[, *mode*]])

Open a `gdbm` database and return a `gdbm` object. The *filename* argument is the name of the database file.

The optional *flag* argument can be:

Value	Meaning
`'r'`	Open existing database for reading only (default)
`'w'`	Open existing database for reading and writing
`'c'`	Open database for reading and writing, creating it if it doesn't exist
`'n'`	Always create a new, empty database, open for reading and writing

The following additional characters may be appended to the flag to control how the database is opened:

Value	Meaning
`'f'`	Open the database in fast mode. Writes to the database will not be synchronized.
`'s'`	Synchronized mode. This will cause changes to the database to be immediately written to the file.
`'u'`	Do not lock database.

Not all flags are valid for all versions of `gdbm`. The module constant `open_flags` is a string of supported flag characters. The exception *error* is raised if an invalid flag is specified.

The optional *mode* argument is the Unix mode of the file, used only when the database has to be created. It defaults to octal `0o666`.

In addition to the dictionary-like methods, `gdbm` objects have the following methods:

`gdbm.firstkey()`
It's possible to loop over every key in the database using this method and the *nextkey()* method. The traversal is ordered by `gdbm`'s internal hash values, and won't be sorted by the key values. This method returns the starting key.

`gdbm.nextkey(`*key*`)`
Returns the key that follows *key* in the traversal. The following code prints every key in the database `db`, without having to create a list in memory that contains them all:

```
k = db.firstkey()
while k != None:
    print(k)
    k = db.nextkey(k)
```

`gdbm.reorganize()`
If you have carried out a lot of deletions and would like to shrink the space used by the `gdbm` file, this routine will reorganize the database. `gdbm` objects will not shorten the length of a database file except by using this reorganization; otherwise, deleted file space will be kept and reused as new (key, value) pairs are added.

`gdbm.sync()`
When the database has been opened in fast mode, this method forces any unwritten data to be written to the disk.

`gdbm.close()`
Close the `gdbm` database.

12.5.2 `dbm.ndbm` — Interface based on ndbm

Source code: Lib/dbm/ndbm.py

The *dbm.ndbm* module provides an interface to the Unix "(n)dbm" library. Dbm objects behave like mappings (dictionaries), except that keys and values are always stored as bytes. Printing a `dbm` object doesn't print the keys and values, and the `items()` and `values()` methods are not supported.

This module can be used with the "classic" ndbm interface or the GNU GDBM compatibility interface. On Unix, the **configure** script will attempt to locate the appropriate header file to simplify building this module.

`exception dbm.ndbm.error`
Raised on *dbm.ndbm*-specific errors, such as I/O errors. *KeyError* is raised for general mapping errors like specifying an incorrect key.

dbm.ndbm.library
: Name of the ndbm implementation library used.

dbm.ndbm.open(*filename*[, *flag*[, *mode*]])
: Open a dbm database and return a ndbm object. The *filename* argument is the name of the database file (without the .dir or .pag extensions).

  The optional *flag* argument must be one of these values:

Value	Meaning
'r'	Open existing database for reading only (default)
'w'	Open existing database for reading and writing
'c'	Open database for reading and writing, creating it if it doesn't exist
'n'	Always create a new, empty database, open for reading and writing

  The optional *mode* argument is the Unix mode of the file, used only when the database has to be created. It defaults to octal 0o666 (and will be modified by the prevailing umask).

  In addition to the dictionary-like methods, ndbm objects provide the following method:

  ndbm.close()
  : Close the ndbm database.

12.5.3 dbm.dumb — Portable DBM implementation

Source code: Lib/dbm/dumb.py

Note: The *dbm.dumb* module is intended as a last resort fallback for the *dbm* module when a more robust module is not available. The *dbm.dumb* module is not written for speed and is not nearly as heavily used as the other database modules.

The *dbm.dumb* module provides a persistent dictionary-like interface which is written entirely in Python. Unlike other modules such as *dbm.gnu* no external library is required. As with other persistent mappings, the keys and values are always stored as bytes.

The module defines the following:

exception dbm.dumb.error
: Raised on *dbm.dumb*-specific errors, such as I/O errors. *KeyError* is raised for general mapping errors like specifying an incorrect key.

dbm.dumb.open(*filename*[, *flag*[, *mode*]])
: Open a dumbdbm database and return a dumbdbm object. The *filename* argument is the basename of the database file (without any specific extensions). When a dumbdbm database is created, files with .dat and .dir extensions are created.

  The optional *flag* argument supports only the semantics of 'c' and 'n' values. Other values will default to database being always opened for update, and will be created if it does not exist.

  The optional *mode* argument is the Unix mode of the file, used only when the database has to be created. It defaults to octal 0o666 (and will be modified by the prevailing umask).

  Warning: It is possible to crash the Python interpreter when loading a database with a sufficiently large/complex entry due to stack depth limitations in Python's AST compiler.

Changed in version 3.5: *open()* always creates a new database when the flag has the value `'n'`.

Deprecated since version 3.6, will be removed in version 3.8: Creating database in `'r'` and `'w'` modes. Modifying database in `'r'` mode.

In addition to the methods provided by the *collections.abc.MutableMapping* class, `dumbdbm` objects provide the following methods:

`dumbdbm.sync()`
Synchronize the on-disk directory and data files. This method is called by the `Shelve.sync()` method.

`dumbdbm.close()`
Close the `dumbdbm` database.

12.6 `sqlite3` — DB-API 2.0 interface for SQLite databases

Source code: Lib/sqlite3/

SQLite is a C library that provides a lightweight disk-based database that doesn't require a separate server process and allows accessing the database using a nonstandard variant of the SQL query language. Some applications can use SQLite for internal data storage. It's also possible to prototype an application using SQLite and then port the code to a larger database such as PostgreSQL or Oracle.

The sqlite3 module was written by Gerhard Häring. It provides a SQL interface compliant with the DB-API 2.0 specification described by **PEP 249**.

To use the module, you must first create a *Connection* object that represents the database. Here the data will be stored in the `example.db` file:

```
import sqlite3
conn = sqlite3.connect('example.db')
```

You can also supply the special name `:memory:` to create a database in RAM.

Once you have a *Connection*, you can create a *Cursor* object and call its *execute()* method to perform SQL commands:

```
c = conn.cursor()

# Create table
c.execute('''CREATE TABLE stocks
             (date text, trans text, symbol text, qty real, price real)''')

# Insert a row of data
c.execute("INSERT INTO stocks VALUES ('2006-01-05','BUY','RHAT',100,35.14)")

# Save (commit) the changes
conn.commit()

# We can also close the connection if we are done with it.
# Just be sure any changes have been committed or they will be lost.
conn.close()
```

The data you've saved is persistent and is available in subsequent sessions:

```
import sqlite3
conn = sqlite3.connect('example.db')
c = conn.cursor()
```

Usually your SQL operations will need to use values from Python variables. You shouldn't assemble your query using Python's string operations because doing so is insecure; it makes your program vulnerable to an SQL injection attack (see https://xkcd.com/327/ for humorous example of what can go wrong).

Instead, use the DB-API's parameter substitution. Put `?` as a placeholder wherever you want to use a value, and then provide a tuple of values as the second argument to the cursor's *execute()* method. (Other database modules may use a different placeholder, such as `%s` or `:1`.) For example:

```
# Never do this -- insecure!
symbol = 'RHAT'
c.execute("SELECT * FROM stocks WHERE symbol = '%s'" % symbol)

# Do this instead
t = ('RHAT',)
c.execute('SELECT * FROM stocks WHERE symbol=?', t)
print(c.fetchone())

# Larger example that inserts many records at a time
purchases = [('2006-03-28', 'BUY', 'IBM', 1000, 45.00),
             ('2006-04-05', 'BUY', 'MSFT', 1000, 72.00),
             ('2006-04-06', 'SELL', 'IBM', 500, 53.00),
            ]
c.executemany('INSERT INTO stocks VALUES (?,?,?,?,?)', purchases)
```

To retrieve data after executing a SELECT statement, you can either treat the cursor as an *iterator*, call the cursor's *fetchone()* method to retrieve a single matching row, or call *fetchall()* to get a list of the matching rows.

This example uses the iterator form:

```
>>> for row in c.execute('SELECT * FROM stocks ORDER BY price'):
        print(row)

('2006-01-05', 'BUY', 'RHAT', 100, 35.14)
('2006-03-28', 'BUY', 'IBM', 1000, 45.0)
('2006-04-06', 'SELL', 'IBM', 500, 53.0)
('2006-04-05', 'BUY', 'MSFT', 1000, 72.0)
```

PEP 249 - Database API Specification 2.0 PEP written by Marc-André Lemburg.

12.6.1 Module functions and constants

`sqlite3.version`
The version number of this module, as a string. This is not the version of the SQLite library.

sqlite3.**version_info**
The version number of this module, as a tuple of integers. This is not the version of the SQLite library.

sqlite3.**sqlite_version**
The version number of the run-time SQLite library, as a string.

sqlite3.**sqlite_version_info**
The version number of the run-time SQLite library, as a tuple of integers.

sqlite3.**PARSE_DECLTYPES**
This constant is meant to be used with the *detect_types* parameter of the *connect()* function.

Setting it makes the *sqlite3* module parse the declared type for each column it returns. It will parse out the first word of the declared type, i. e. for "integer primary key", it will parse out "integer", or for "number(10)" it will parse out "number". Then for that column, it will look into the converters dictionary and use the converter function registered for that type there.

sqlite3.**PARSE_COLNAMES**
This constant is meant to be used with the *detect_types* parameter of the *connect()* function.

Setting this makes the SQLite interface parse the column name for each column it returns. It will look for a string formed [mytype] in there, and then decide that 'mytype' is the type of the column. It will try to find an entry of 'mytype' in the converters dictionary and then use the converter function found there to return the value. The column name found in *Cursor.description* is only the first word of the column name, i. e. if you use something like `'as "x [datetime]"'` in your SQL, then we will parse out everything until the first blank for the column name: the column name would simply be "x".

sqlite3.**connect**(*database*[, *timeout*, *detect_types*, *isolation_level*, *check_same_thread*, *factory*, *cached_statements*, *uri*])
Opens a connection to the SQLite database file *database*. By default returns a *Connection* object, unless a custom *factory* is given.

database is a *path-like object* giving the pathname (absolute or relative to the current working directory) of the database file to be opened. You can use `":memory:"` to open a database connection to a database that resides in RAM instead of on disk.

When a database is accessed by multiple connections, and one of the processes modifies the database, the SQLite database is locked until that transaction is committed. The *timeout* parameter specifies how long the connection should wait for the lock to go away until raising an exception. The default for the timeout parameter is 5.0 (five seconds).

For the *isolation_level* parameter, please see the *isolation_level* property of *Connection* objects.

SQLite natively supports only the types TEXT, INTEGER, REAL, BLOB and NULL. If you want to use other types you must add support for them yourself. The *detect_types* parameter and the using custom **converters** registered with the module-level *register_converter()* function allow you to easily do that.

detect_types defaults to 0 (i. e. off, no type detection), you can set it to any combination of *PARSE_DECLTYPES* and *PARSE_COLNAMES* to turn type detection on.

By default, *check_same_thread* is *True* and only the creating thread may use the connection. If set *False*, the returned connection may be shared across multiple threads. When using multiple threads with the same connection writing operations should be serialized by the user to avoid data corruption.

By default, the *sqlite3* module uses its *Connection* class for the connect call. You can, however, subclass the *Connection* class and make *connect()* use your class instead by providing your class for the *factory* parameter.

Consult the section *SQLite and Python types* of this manual for details.

The *sqlite3* module internally uses a statement cache to avoid SQL parsing overhead. If you want to explicitly set the number of statements that are cached for the connection, you can set the *cached_statements* parameter. The currently implemented default is to cache 100 statements.

If *uri* is true, *database* is interpreted as a URI. This allows you to specify options. For example, to open a database in read-only mode you can use:

```
db = sqlite3.connect('file:path/to/database?mode=ro', uri=True)
```

More information about this feature, including a list of recognized options, can be found in the SQLite URI documentation.

Changed in version 3.4: Added the *uri* parameter.

Changed in version 3.7: *database* can now also be a *path-like object*, not only a string.

sqlite3.register_converter(*typename*, *callable*)
Registers a callable to convert a bytestring from the database into a custom Python type. The callable will be invoked for all database values that are of the type *typename*. Confer the parameter *detect_types* of the *connect()* function for how the type detection works. Note that *typename* and the name of the type in your query are matched in case-insensitive manner.

sqlite3.register_adapter(*type*, *callable*)
Registers a callable to convert the custom Python type *type* into one of SQLite's supported types. The callable *callable* accepts as single parameter the Python value, and must return a value of the following types: int, float, str or bytes.

sqlite3.complete_statement(*sql*)
Returns *True* if the string *sql* contains one or more complete SQL statements terminated by semicolons. It does not verify that the SQL is syntactically correct, only that there are no unclosed string literals and the statement is terminated by a semicolon.

This can be used to build a shell for SQLite, as in the following example:

```
# A minimal SQLite shell for experiments

import sqlite3

con = sqlite3.connect(":memory:")
con.isolation_level = None
cur = con.cursor()

buffer = ""

print("Enter your SQL commands to execute in sqlite3.")
print("Enter a blank line to exit.")

while True:
    line = input()
    if line == "":
        break
    buffer += line
    if sqlite3.complete_statement(buffer):
        try:
            buffer = buffer.strip()
            cur.execute(buffer)

            if buffer.lstrip().upper().startswith("SELECT"):
                print(cur.fetchall())
        except sqlite3.Error as e:
```

(continues on next page)

(continued from previous page)

```
            print("An error occurred:", e.args[0])
        buffer = ""

con.close()
```

sqlite3.**enable_callback_tracebacks**(*flag*)
By default you will not get any tracebacks in user-defined functions, aggregates, converters, authorizer callbacks etc. If you want to debug them, you can call this function with *flag* set to `True`. Afterwards, you will get tracebacks from callbacks on `sys.stderr`. Use *False* to disable the feature again.

12.6.2 Connection Objects

class sqlite3.**Connection**
A SQLite database connection has the following attributes and methods:

isolation_level
Get or set the current isolation level. *None* for autocommit mode or one of "DEFERRED", "IMMEDIATE" or "EXCLUSIVE". See section *Controlling Transactions* for a more detailed explanation.

in_transaction
True if a transaction is active (there are uncommitted changes), *False* otherwise. Read-only attribute.

New in version 3.2.

cursor(*factory=Cursor*)
The cursor method accepts a single optional parameter *factory*. If supplied, this must be a callable returning an instance of *Cursor* or its subclasses.

commit()
This method commits the current transaction. If you don't call this method, anything you did since the last call to `commit()` is not visible from other database connections. If you wonder why you don't see the data you've written to the database, please check you didn't forget to call this method.

rollback()
This method rolls back any changes to the database since the last call to *commit()*.

close()
This closes the database connection. Note that this does not automatically call *commit()*. If you just close your database connection without calling *commit()* first, your changes will be lost!

execute(*sql*[, *parameters*])
This is a nonstandard shortcut that creates a cursor object by calling the *cursor()* method, calls the cursor's *execute()* method with the *parameters* given, and returns the cursor.

executemany(*sql*[, *parameters*])
This is a nonstandard shortcut that creates a cursor object by calling the *cursor()* method, calls the cursor's *executemany()* method with the *parameters* given, and returns the cursor.

executescript(*sql_script*)
This is a nonstandard shortcut that creates a cursor object by calling the *cursor()* method, calls the cursor's *executescript()* method with the given *sql_script*, and returns the cursor.

create_function(*name*, *num_params*, *func*)
Creates a user-defined function that you can later use from within SQL statements under the function name *name*. *num_params* is the number of parameters the function accepts (if *num_params*

is -1, the function may take any number of arguments), and *func* is a Python callable that is called as the SQL function.

The function can return any of the types supported by SQLite: bytes, str, int, float and `None`.

Example:

```
import sqlite3
import hashlib

def md5sum(t):
    return hashlib.md5(t).hexdigest()

con = sqlite3.connect(":memory:")
con.create_function("md5", 1, md5sum)
cur = con.cursor()
cur.execute("select md5(?)", (b"foo",))
print(cur.fetchone()[0])
```

create_aggregate(*name*, *num_params*, *aggregate_class*)

Creates a user-defined aggregate function.

The aggregate class must implement a `step` method, which accepts the number of parameters *num_params* (if *num_params* is -1, the function may take any number of arguments), and a `finalize` method which will return the final result of the aggregate.

The `finalize` method can return any of the types supported by SQLite: bytes, str, int, float and `None`.

Example:

```
import sqlite3

class MySum:
    def __init__(self):
        self.count = 0

    def step(self, value):
        self.count += value

    def finalize(self):
        return self.count

con = sqlite3.connect(":memory:")
con.create_aggregate("mysum", 1, MySum)
cur = con.cursor()
cur.execute("create table test(i)")
cur.execute("insert into test(i) values (1)")
cur.execute("insert into test(i) values (2)")
cur.execute("select mysum(i) from test")
print(cur.fetchone()[0])
```

create_collation(*name*, *callable*)

Creates a collation with the specified *name* and *callable*. The callable will be passed two string arguments. It should return -1 if the first is ordered lower than the second, 0 if they are ordered equal and 1 if the first is ordered higher than the second. Note that this controls sorting (ORDER BY in SQL) so your comparisons don't affect other SQL operations.

Note that the callable will get its parameters as Python bytestrings, which will normally be encoded in UTF-8.

The following example shows a custom collation that sorts "the wrong way":

```
import sqlite3

def collate_reverse(string1, string2):
    if string1 == string2:
        return 0
    elif string1 < string2:
        return 1
    else:
        return -1

con = sqlite3.connect(":memory:")
con.create_collation("reverse", collate_reverse)

cur = con.cursor()
cur.execute("create table test(x)")
cur.executemany("insert into test(x) values (?)", [("a",), ("b",)])
cur.execute("select x from test order by x collate reverse")
for row in cur:
    print(row)
con.close()
```

To remove a collation, call `create_collation` with `None` as callable:

```
con.create_collation("reverse", None)
```

interrupt()
You can call this method from a different thread to abort any queries that might be executing on the connection. The query will then abort and the caller will get an exception.

set_authorizer(*authorizer_callback*)
This routine registers a callback. The callback is invoked for each attempt to access a column of a table in the database. The callback should return `SQLITE_OK` if access is allowed, `SQLITE_DENY` if the entire SQL statement should be aborted with an error and `SQLITE_IGNORE` if the column should be treated as a NULL value. These constants are available in the *sqlite3* module.

The first argument to the callback signifies what kind of operation is to be authorized. The second and third argument will be arguments or *None* depending on the first argument. The 4th argument is the name of the database ("main", "temp", etc.) if applicable. The 5th argument is the name of the inner-most trigger or view that is responsible for the access attempt or *None* if this access attempt is directly from input SQL code.

Please consult the SQLite documentation about the possible values for the first argument and the meaning of the second and third argument depending on the first one. All necessary constants are available in the *sqlite3* module.

set_progress_handler(*handler*, *n*)
This routine registers a callback. The callback is invoked for every *n* instructions of the SQLite virtual machine. This is useful if you want to get called from SQLite during long-running operations, for example to update a GUI.

If you want to clear any previously installed progress handler, call the method with *None* for *handler*.

Returning a non-zero value from the handler function will terminate the currently executing query and cause it to raise an *OperationalError* exception.

set_trace_callback(*trace_callback*)
Registers *trace_callback* to be called for each SQL statement that is actually executed by the

SQLite backend.

The only argument passed to the callback is the statement (as string) that is being executed. The return value of the callback is ignored. Note that the backend does not only run statements passed to the *Cursor.execute()* methods. Other sources include the transaction management of the Python module and the execution of triggers defined in the current database.

Passing *None* as *trace_callback* will disable the trace callback.

New in version 3.3.

enable_load_extension(*enabled*)

This routine allows/disallows the SQLite engine to load SQLite extensions from shared libraries. SQLite extensions can define new functions, aggregates or whole new virtual table implementations. One well-known extension is the fulltext-search extension distributed with SQLite.

Loadable extensions are disabled by default. See[1].

New in version 3.2.

```
import sqlite3

con = sqlite3.connect(":memory:")

# enable extension loading
con.enable_load_extension(True)

# Load the fulltext search extension
con.execute("select load_extension('./fts3.so')")

# alternatively you can load the extension using an API call:
# con.load_extension("./fts3.so")

# disable extension loading again
con.enable_load_extension(False)

# example from SQLite wiki
con.execute("create virtual table recipe using fts3(name, ingredients)")
con.executescript("""
    insert into recipe (name, ingredients) values ('broccoli stew', 'broccoli peppers␣
↪cheese tomatoes');
    insert into recipe (name, ingredients) values ('pumpkin stew', 'pumpkin onions␣
↪garlic celery');
    insert into recipe (name, ingredients) values ('broccoli pie', 'broccoli cheese␣
↪onions flour');
    insert into recipe (name, ingredients) values ('pumpkin pie', 'pumpkin sugar flour␣
↪butter');
    """)
for row in con.execute("select rowid, name, ingredients from recipe where name match 'pie
↪'"):
    print(row)
```

load_extension(*path*)

This routine loads a SQLite extension from a shared library. You have to enable extension loading with *enable_load_extension()* before you can use this routine.

Loadable extensions are disabled by default. See[1].

[1] The sqlite3 module is not built with loadable extension support by default, because some platforms (notably Mac OS X) have SQLite libraries which are compiled without this feature. To get loadable extension support, you must pass –enable-loadable-sqlite-extensions to configure.

New in version 3.2.

row_factory

You can change this attribute to a callable that accepts the cursor and the original row as a tuple and will return the real result row. This way, you can implement more advanced ways of returning results, such as returning an object that can also access columns by name.

Example:

```
import sqlite3

def dict_factory(cursor, row):
    d = {}
    for idx, col in enumerate(cursor.description):
        d[col[0]] = row[idx]
    return d

con = sqlite3.connect(":memory:")
con.row_factory = dict_factory
cur = con.cursor()
cur.execute("select 1 as a")
print(cur.fetchone()["a"])
```

If returning a tuple doesn't suffice and you want name-based access to columns, you should consider setting *row_factory* to the highly-optimized *sqlite3.Row* type. *Row* provides both index-based and case-insensitive name-based access to columns with almost no memory overhead. It will probably be better than your own custom dictionary-based approach or even a db_row based solution.

text_factory

Using this attribute you can control what objects are returned for the TEXT data type. By default, this attribute is set to *str* and the *sqlite3* module will return Unicode objects for TEXT. If you want to return bytestrings instead, you can set it to *bytes*.

You can also set it to any other callable that accepts a single bytestring parameter and returns the resulting object.

See the following example code for illustration:

```
import sqlite3

con = sqlite3.connect(":memory:")
cur = con.cursor()

AUSTRIA = "\xd6sterreich"

# by default, rows are returned as Unicode
cur.execute("select ?", (AUSTRIA,))
row = cur.fetchone()
assert row[0] == AUSTRIA

# but we can make sqlite3 always return bytestrings ...
con.text_factory = bytes
cur.execute("select ?", (AUSTRIA,))
row = cur.fetchone()
assert type(row[0]) is bytes
# the bytestrings will be encoded in UTF-8, unless you stored garbage in the
# database ...
assert row[0] == AUSTRIA.encode("utf-8")
```

(continues on next page)

(continued from previous page)

```
# we can also implement a custom text_factory ...
# here we implement one that appends "foo" to all strings
con.text_factory = lambda x: x.decode("utf-8") + "foo"
cur.execute("select ?", ("bar",))
row = cur.fetchone()
assert row[0] == "barfoo"
```

total_changes
Returns the total number of database rows that have been modified, inserted, or deleted since the database connection was opened.

iterdump()
Returns an iterator to dump the database in an SQL text format. Useful when saving an in-memory database for later restoration. This function provides the same capabilities as the `.dump` command in the **sqlite3** shell.

Example:

```
# Convert file existing_db.db to SQL dump file dump.sql
import sqlite3

con = sqlite3.connect('existing_db.db')
with open('dump.sql', 'w') as f:
    for line in con.iterdump():
        f.write('%s\n' % line)
```

backup(*target*, ***, *pages=0*, *progress=None*, *name="main"*, *sleep=0.250*)
This method makes a backup of a SQLite database even while it's being accessed by other clients, or concurrently by the same connection. The copy will be written into the mandatory argument *target*, that must be another *Connection* instance.

By default, or when *pages* is either `0` or a negative integer, the entire database is copied in a single step; otherwise the method performs a loop copying up to *pages* pages at a time.

If *progress* is specified, it must either be `None` or a callable object that will be executed at each iteration with three integer arguments, respectively the *status* of the last iteration, the *remaining* number of pages still to be copied and the *total* number of pages.

The *name* argument specifies the database name that will be copied: it must be a string containing either `"main"`, the default, to indicate the main database, `"temp"` to indicate the temporary database or the name specified after the `AS` keyword in an `ATTACH DATABASE` statement for an attached database.

The *sleep* argument specifies the number of seconds to sleep by between successive attempts to backup remaining pages, can be specified either as an integer or a floating point value.

Example 1, copy an existing database into another:

```
import sqlite3

def progress(status, remaining, total):
    print(f'Copied {total-remaining} of {total} pages...')

con = sqlite3.connect('existing_db.db')
with sqlite3.connect('backup.db') as bck:
    con.backup(bck, pages=1, progress=progress)
```

Example 2, copy an existing database into a transient copy:

```
import sqlite3

source = sqlite3.connect('existing_db.db')
dest = sqlite3.connect(':memory:')
source.backup(dest)
```

Availability: SQLite 3.6.11 or higher

New in version 3.7.

12.6.3 Cursor Objects

class sqlite3.Cursor

A *Cursor* instance has the following attributes and methods.

execute(*sql*[, *parameters*])

Executes an SQL statement. The SQL statement may be parameterized (i. e. placeholders instead of SQL literals). The *sqlite3* module supports two kinds of placeholders: question marks (qmark style) and named placeholders (named style).

Here's an example of both styles:

```
import sqlite3

con = sqlite3.connect(":memory:")
cur = con.cursor()
cur.execute("create table people (name_last, age)")

who = "Yeltsin"
age = 72

# This is the qmark style:
cur.execute("insert into people values (?, ?)", (who, age))

# And this is the named style:
cur.execute("select * from people where name_last=:who and age=:age", {"who": who, "age
↪": age})

print(cur.fetchone())
```

execute() will only execute a single SQL statement. If you try to execute more than one statement with it, it will raise a *Warning*. Use *executescript()* if you want to execute multiple SQL statements with one call.

executemany(*sql*, *seq_of_parameters*)

Executes an SQL command against all parameter sequences or mappings found in the sequence *seq_of_parameters*. The *sqlite3* module also allows using an *iterator* yielding parameters instead of a sequence.

```
import sqlite3

class IterChars:
    def __init__(self):
        self.count = ord('a')

    def __iter__(self):
        return self
```

(continues on next page)

(continued from previous page)

```
    def __next__(self):
        if self.count > ord('z'):
            raise StopIteration
        self.count += 1
        return (chr(self.count - 1),) # this is a 1-tuple

con = sqlite3.connect(":memory:")
cur = con.cursor()
cur.execute("create table characters(c)")

theIter = IterChars()
cur.executemany("insert into characters(c) values (?)", theIter)

cur.execute("select c from characters")
print(cur.fetchall())
```

Here's a shorter example using a *generator*:

```
import sqlite3
import string

def char_generator():
    for c in string.ascii_lowercase:
        yield (c,)

con = sqlite3.connect(":memory:")
cur = con.cursor()
cur.execute("create table characters(c)")

cur.executemany("insert into characters(c) values (?)", char_generator())

cur.execute("select c from characters")
print(cur.fetchall())
```

executescript(*sql_script*)

This is a nonstandard convenience method for executing multiple SQL statements at once. It issues a `COMMIT` statement first, then executes the SQL script it gets as a parameter.

sql_script can be an instance of *str*.

Example:

```
import sqlite3

con = sqlite3.connect(":memory:")
cur = con.cursor()
cur.executescript("""
    create table person(
        firstname,
        lastname,
        age
    );

    create table book(
        title,
        author,
```

(continues on next page)

(continued from previous page)

```
        published
    );

    insert into book(title, author, published)
    values (
        'Dirk Gently''s Holistic Detective Agency',
        'Douglas Adams',
        1987
    );
    """)
```

fetchone()
Fetches the next row of a query result set, returning a single sequence, or *None* when no more data is available.

fetchmany(*size=cursor.arraysize*)
Fetches the next set of rows of a query result, returning a list. An empty list is returned when no more rows are available.

The number of rows to fetch per call is specified by the *size* parameter. If it is not given, the cursor's arraysize determines the number of rows to be fetched. The method should try to fetch as many rows as indicated by the size parameter. If this is not possible due to the specified number of rows not being available, fewer rows may be returned.

Note there are performance considerations involved with the *size* parameter. For optimal performance, it is usually best to use the arraysize attribute. If the *size* parameter is used, then it is best for it to retain the same value from one *fetchmany()* call to the next.

fetchall()
Fetches all (remaining) rows of a query result, returning a list. Note that the cursor's arraysize attribute can affect the performance of this operation. An empty list is returned when no rows are available.

close()
Close the cursor now (rather than whenever `__del__` is called).

The cursor will be unusable from this point forward; a *ProgrammingError* exception will be raised if any operation is attempted with the cursor.

rowcount
Although the *Cursor* class of the *sqlite3* module implements this attribute, the database engine's own support for the determination of "rows affected"/"rows selected" is quirky.

For *executemany()* statements, the number of modifications are summed up into *rowcount*.

As required by the Python DB API Spec, the *rowcount* attribute "is -1 in case no `executeXX()` has been performed on the cursor or the rowcount of the last operation is not determinable by the interface". This includes `SELECT` statements because we cannot determine the number of rows a query produced until all rows were fetched.

With SQLite versions before 3.6.5, *rowcount* is set to 0 if you make a `DELETE FROM table` without any condition.

lastrowid
This read-only attribute provides the rowid of the last modified row. It is only set if you issued an `INSERT` or a `REPLACE` statement using the *execute()* method. For operations other than `INSERT` or `REPLACE` or when *executemany()* is called, *lastrowid* is set to *None*.

If the `INSERT` or `REPLACE` statement failed to insert the previous successful rowid is returned.

Changed in version 3.6: Added support for the `REPLACE` statement.

arraysize
Read/write attribute that controls the number of rows returned by *fetchmany()*. The default value is 1 which means a single row would be fetched per call.

description
This read-only attribute provides the column names of the last query. To remain compatible with the Python DB API, it returns a 7-tuple for each column where the last six items of each tuple are *None*.

It is set for SELECT statements without any matching rows as well.

connection
This read-only attribute provides the SQLite database *Connection* used by the *Cursor* object. A *Cursor* object created by calling *con.cursor()* will have a *connection* attribute that refers to *con*:

```
>>> con = sqlite3.connect(":memory:")
>>> cur = con.cursor()
>>> cur.connection == con
True
```

12.6.4 Row Objects

class sqlite3.Row
A *Row* instance serves as a highly optimized *row_factory* for *Connection* objects. It tries to mimic a tuple in most of its features.

It supports mapping access by column name and index, iteration, representation, equality testing and *len()*.

If two *Row* objects have exactly the same columns and their members are equal, they compare equal.

keys()
This method returns a list of column names. Immediately after a query, it is the first member of each tuple in *Cursor.description*.

Changed in version 3.5: Added support of slicing.

Let's assume we initialize a table as in the example given above:

```
conn = sqlite3.connect(":memory:")
c = conn.cursor()
c.execute('''create table stocks
(date text, trans text, symbol text,
 qty real, price real)''')
c.execute("""insert into stocks
          values ('2006-01-05','BUY','RHAT',100,35.14)""")
conn.commit()
c.close()
```

Now we plug *Row* in:

```
>>> conn.row_factory = sqlite3.Row
>>> c = conn.cursor()
>>> c.execute('select * from stocks')
<sqlite3.Cursor object at 0x7f4e7dd8fa80>
>>> r = c.fetchone()
>>> type(r)
<class 'sqlite3.Row'>
```

(continues on next page)

(continued from previous page)

```
>>> tuple(r)
('2006-01-05', 'BUY', 'RHAT', 100.0, 35.14)
>>> len(r)
5
>>> r[2]
'RHAT'
>>> r.keys()
['date', 'trans', 'symbol', 'qty', 'price']
>>> r['qty']
100.0
>>> for member in r:
...     print(member)
...
2006-01-05
BUY
RHAT
100.0
35.14
```

12.6.5 Exceptions

exception sqlite3.Warning
A subclass of *Exception*.

exception sqlite3.Error
The base class of the other exceptions in this module. It is a subclass of *Exception*.

exception sqlite3.DatabaseError
Exception raised for errors that are related to the database.

exception sqlite3.IntegrityError
Exception raised when the relational integrity of the database is affected, e.g. a foreign key check fails. It is a subclass of *DatabaseError*.

exception sqlite3.ProgrammingError
Exception raised for programming errors, e.g. table not found or already exists, syntax error in the SQL statement, wrong number of parameters specified, etc. It is a subclass of *DatabaseError*.

exception sqlite3.OperationalError
Exception raised for errors that are related to the database's operation and not necessarily under the control of the programmer, e.g. an unexpected disconnect occurs, the data source name is not found, a transaction could not be processed, etc. It is a subclass of *DatabaseError*.

12.6.6 SQLite and Python types

Introduction

SQLite natively supports the following types: `NULL`, `INTEGER`, `REAL`, `TEXT`, `BLOB`.

The following Python types can thus be sent to SQLite without any problem:

Python type	SQLite type
None	NULL
int	INTEGER
float	REAL
str	TEXT
bytes	BLOB

This is how SQLite types are converted to Python types by default:

SQLite type	Python type
NULL	*None*
INTEGER	*int*
REAL	*float*
TEXT	depends on *text_factory*, *str* by default
BLOB	*bytes*

The type system of the *sqlite3* module is extensible in two ways: you can store additional Python types in a SQLite database via object adaptation, and you can let the *sqlite3* module convert SQLite types to different Python types via converters.

Using adapters to store additional Python types in SQLite databases

As described before, SQLite supports only a limited set of types natively. To use other Python types with SQLite, you must **adapt** them to one of the sqlite3 module's supported types for SQLite: one of NoneType, int, float, str, bytes.

There are two ways to enable the *sqlite3* module to adapt a custom Python type to one of the supported ones.

Letting your object adapt itself

This is a good approach if you write the class yourself. Let's suppose you have a class like this:

```
class Point:
    def __init__(self, x, y):
        self.x, self.y = x, y
```

Now you want to store the point in a single SQLite column. First you'll have to choose one of the supported types first to be used for representing the point. Let's just use str and separate the coordinates using a semicolon. Then you need to give your class a method `__conform__(self, protocol)` which must return the converted value. The parameter *protocol* will be `PrepareProtocol`.

```
import sqlite3

class Point:
    def __init__(self, x, y):
        self.x, self.y = x, y

    def __conform__(self, protocol):
        if protocol is sqlite3.PrepareProtocol:
            return "%f;%f" % (self.x, self.y)
```

(continues on next page)

(continued from previous page)

```
con = sqlite3.connect(":memory:")
cur = con.cursor()

p = Point(4.0, -3.2)
cur.execute("select ?", (p,))
print(cur.fetchone()[0])
```

Registering an adapter callable

The other possibility is to create a function that converts the type to the string representation and register the function with *register_adapter()*.

```
import sqlite3

class Point:
    def __init__(self, x, y):
        self.x, self.y = x, y

def adapt_point(point):
    return "%f;%f" % (point.x, point.y)

sqlite3.register_adapter(Point, adapt_point)

con = sqlite3.connect(":memory:")
cur = con.cursor()

p = Point(4.0, -3.2)
cur.execute("select ?", (p,))
print(cur.fetchone()[0])
```

The *sqlite3* module has two default adapters for Python's built-in *datetime.date* and *datetime.datetime* types. Now let's suppose we want to store *datetime.datetime* objects not in ISO representation, but as a Unix timestamp.

```
import sqlite3
import datetime
import time

def adapt_datetime(ts):
    return time.mktime(ts.timetuple())

sqlite3.register_adapter(datetime.datetime, adapt_datetime)

con = sqlite3.connect(":memory:")
cur = con.cursor()

now = datetime.datetime.now()
cur.execute("select ?", (now,))
print(cur.fetchone()[0])
```

Converting SQLite values to custom Python types

Writing an adapter lets you send custom Python types to SQLite. But to make it really useful we need to make the Python to SQLite to Python roundtrip work.

Enter converters.

Let's go back to the `Point` class. We stored the x and y coordinates separated via semicolons as strings in SQLite.

First, we'll define a converter function that accepts the string as a parameter and constructs a `Point` object from it.

Note: Converter functions **always** get called with a *bytes* object, no matter under which data type you sent the value to SQLite.

```
def convert_point(s):
    x, y = map(float, s.split(b";"))
    return Point(x, y)
```

Now you need to make the *sqlite3* module know that what you select from the database is actually a point. There are two ways of doing this:

- Implicitly via the declared type
- Explicitly via the column name

Both ways are described in section *Module functions and constants*, in the entries for the constants *PARSE_DECLTYPES* and *PARSE_COLNAMES*.

The following example illustrates both approaches.

```
import sqlite3

class Point:
    def __init__(self, x, y):
        self.x, self.y = x, y

    def __repr__(self):
        return "(%f;%f)" % (self.x, self.y)

def adapt_point(point):
    return ("%f;%f" % (point.x, point.y)).encode('ascii')

def convert_point(s):
    x, y = list(map(float, s.split(b";")))
    return Point(x, y)

# Register the adapter
sqlite3.register_adapter(Point, adapt_point)

# Register the converter
sqlite3.register_converter("point", convert_point)

p = Point(4.0, -3.2)

#########################
# 1) Using declared types
con = sqlite3.connect(":memory:", detect_types=sqlite3.PARSE_DECLTYPES)
cur = con.cursor()
cur.execute("create table test(p point)")

cur.execute("insert into test(p) values (?)", (p,))
cur.execute("select p from test")
```

(continues on next page)

(continued from previous page)

```
print("with declared types:", cur.fetchone()[0])
cur.close()
con.close()

#######################
# 1) Using column names
con = sqlite3.connect(":memory:", detect_types=sqlite3.PARSE_COLNAMES)
cur = con.cursor()
cur.execute("create table test(p)")

cur.execute("insert into test(p) values (?)", (p,))
cur.execute('select p as "p [point]" from test')
print("with column names:", cur.fetchone()[0])
cur.close()
con.close()
```

Default adapters and converters

There are default adapters for the date and datetime types in the datetime module. They will be sent as ISO dates/ISO timestamps to SQLite.

The default converters are registered under the name "date" for *datetime.date* and under the name "timestamp" for *datetime.datetime*.

This way, you can use date/timestamps from Python without any additional fiddling in most cases. The format of the adapters is also compatible with the experimental SQLite date/time functions.

The following example demonstrates this.

```
import sqlite3
import datetime

con = sqlite3.connect(":memory:", detect_types=sqlite3.PARSE_DECLTYPES|sqlite3.PARSE_COLNAMES)
cur = con.cursor()
cur.execute("create table test(d date, ts timestamp)")

today = datetime.date.today()
now = datetime.datetime.now()

cur.execute("insert into test(d, ts) values (?, ?)", (today, now))
cur.execute("select d, ts from test")
row = cur.fetchone()
print(today, "=>", row[0], type(row[0]))
print(now, "=>", row[1], type(row[1]))

cur.execute('select current_date as "d [date]", current_timestamp as "ts [timestamp]"')
row = cur.fetchone()
print("current_date", row[0], type(row[0]))
print("current_timestamp", row[1], type(row[1]))
```

If a timestamp stored in SQLite has a fractional part longer than 6 numbers, its value will be truncated to microsecond precision by the timestamp converter.

12.6.7 Controlling Transactions

By default, the *sqlite3* module opens transactions implicitly before a Data Modification Language (DML) statement (i.e. INSERT/UPDATE/DELETE/REPLACE).

You can control which kind of BEGIN statements sqlite3 implicitly executes (or none at all) via the *isolation_level* parameter to the *connect()* call, or via the isolation_level property of connections.

If you want **autocommit mode**, then set isolation_level to None.

Otherwise leave it at its default, which will result in a plain "BEGIN" statement, or set it to one of SQLite's supported isolation levels: "DEFERRED", "IMMEDIATE" or "EXCLUSIVE".

The current transaction state is exposed through the *Connection.in_transaction* attribute of the connection object.

Changed in version 3.6: *sqlite3* used to implicitly commit an open transaction before DDL statements. This is no longer the case.

12.6.8 Using sqlite3 efficiently

Using shortcut methods

Using the nonstandard execute(), executemany() and executescript() methods of the *Connection* object, your code can be written more concisely because you don't have to create the (often superfluous) *Cursor* objects explicitly. Instead, the *Cursor* objects are created implicitly and these shortcut methods return the cursor objects. This way, you can execute a SELECT statement and iterate over it directly using only a single call on the *Connection* object.

```
import sqlite3

persons = [
    ("Hugo", "Boss"),
    ("Calvin", "Klein")
    ]

con = sqlite3.connect(":memory:")

# Create the table
con.execute("create table person(firstname, lastname)")

# Fill the table
con.executemany("insert into person(firstname, lastname) values (?, ?)", persons)

# Print the table contents
for row in con.execute("select firstname, lastname from person"):
    print(row)

print("I just deleted", con.execute("delete from person").rowcount, "rows")
```

Accessing columns by name instead of by index

One useful feature of the *sqlite3* module is the built-in *sqlite3.Row* class designed to be used as a row factory.

Rows wrapped with this class can be accessed both by index (like tuples) and case-insensitively by name:

```
import sqlite3

con = sqlite3.connect(":memory:")
con.row_factory = sqlite3.Row

cur = con.cursor()
cur.execute("select 'John' as name, 42 as age")
for row in cur:
    assert row[0] == row["name"]
    assert row["name"] == row["nAmE"]
    assert row[1] == row["age"]
    assert row[1] == row["AgE"]
```

Using the connection as a context manager

Connection objects can be used as context managers that automatically commit or rollback transactions. In the event of an exception, the transaction is rolled back; otherwise, the transaction is committed:

```
import sqlite3

con = sqlite3.connect(":memory:")
con.execute("create table person (id integer primary key, firstname varchar unique)")

# Successful, con.commit() is called automatically afterwards
with con:
    con.execute("insert into person(firstname) values (?)", ("Joe",))

# con.rollback() is called after the with block finishes with an exception, the
# exception is still raised and must be caught
try:
    with con:
        con.execute("insert into person(firstname) values (?)", ("Joe",))
except sqlite3.IntegrityError:
    print("couldn't add Joe twice")
```

12.6.9 Common issues

Multithreading

Older SQLite versions had issues with sharing connections between threads. That's why the Python module disallows sharing connections and cursors between threads. If you still try to do so, you will get an exception at runtime.

The only exception is calling the *interrupt()* method, which only makes sense to call from a different thread.

CHAPTER

THIRTEEN

DATA COMPRESSION AND ARCHIVING

The modules described in this chapter support data compression with the zlib, gzip, bzip2 and lzma algorithms, and the creation of ZIP- and tar-format archives. See also *Archiving operations* provided by the *shutil* module.

13.1 zlib — Compression compatible with gzip

For applications that require data compression, the functions in this module allow compression and decompression, using the zlib library. The zlib library has its own home page at http://www.zlib.net. There are known incompatibilities between the Python module and versions of the zlib library earlier than 1.1.3; 1.1.3 has a security vulnerability, so we recommend using 1.1.4 or later.

zlib's functions have many options and often need to be used in a particular order. This documentation doesn't attempt to cover all of the permutations; consult the zlib manual at http://www.zlib.net/manual.html for authoritative information.

For reading and writing `.gz` files see the *gzip* module.

The available exception and functions in this module are:

exception zlib.error
Exception raised on compression and decompression errors.

zlib.adler32(*data*[, *value*])
Computes an Adler-32 checksum of *data*. (An Adler-32 checksum is almost as reliable as a CRC32 but can be computed much more quickly.) The result is an unsigned 32-bit integer. If *value* is present, it is used as the starting value of the checksum; otherwise, a default value of 1 is used. Passing in *value* allows computing a running checksum over the concatenation of several inputs. The algorithm is not cryptographically strong, and should not be used for authentication or digital signatures. Since the algorithm is designed for use as a checksum algorithm, it is not suitable for use as a general hash algorithm.

Changed in version 3.0: Always returns an unsigned value. To generate the same numeric value across all Python versions and platforms, use `adler32(data) & 0xffffffff`.

zlib.compress(*data*, *level=-1*)
Compresses the bytes in *data*, returning a bytes object containing compressed data. *level* is an integer from `0` to `9` or `-1` controlling the level of compression; `1` (Z_BEST_SPEED) is fastest and produces the least compression, `9` (Z_BEST_COMPRESSION) is slowest and produces the most. `0` (Z_NO_COMPRESSION) is no compression. The default value is `-1` (Z_DEFAULT_COMPRESSION). Z_DEFAULT_COMPRESSION represents a default compromise between speed and compression (currently equivalent to level 6). Raises the *error* exception if any error occurs.

Changed in version 3.6: *level* can now be used as a keyword parameter.

zlib.compressobj(*level=-1*, *method=DEFLATED*, *wbits=MAX_WBITS*, *memLevel=DEF_MEM_LEVEL*, *strategy=Z_DEFAULT_STRATEGY*[, *zdict*])

Returns a compression object, to be used for compressing data streams that won't fit into memory at once.

level is the compression level – an integer from `0` to `9` or `-1`. A value of `1` (Z_BEST_SPEED) is fastest and produces the least compression, while a value of `9` (Z_BEST_COMPRESSION) is slowest and produces the most. `0` (Z_NO_COMPRESSION) is no compression. The default value is `-1` (Z_DEFAULT_COMPRESSION). Z_DEFAULT_COMPRESSION represents a default compromise between speed and compression (currently equivalent to level 6).

method is the compression algorithm. Currently, the only supported value is `DEFLATED`.

The *wbits* argument controls the size of the history buffer (or the "window size") used when compressing data, and whether a header and trailer is included in the output. It can take several ranges of values, defaulting to `15` (MAX_WBITS):

- +9 to +15: The base-two logarithm of the window size, which therefore ranges between 512 and 32768. Larger values produce better compression at the expense of greater memory usage. The resulting output will include a zlib-specific header and trailer.
- −9 to −15: Uses the absolute value of *wbits* as the window size logarithm, while producing a raw output stream with no header or trailing checksum.
- +25 to +31 = 16 + (9 to 15): Uses the low 4 bits of the value as the window size logarithm, while including a basic **gzip** header and trailing checksum in the output.

The *memLevel* argument controls the amount of memory used for the internal compression state. Valid values range from `1` to `9`. Higher values use more memory, but are faster and produce smaller output.

strategy is used to tune the compression algorithm. Possible values are `Z_DEFAULT_STRATEGY`, `Z_FILTERED`, `Z_HUFFMAN_ONLY`, `Z_RLE` (zlib 1.2.0.1) and `Z_FIXED` (zlib 1.2.2.2).

zdict is a predefined compression dictionary. This is a sequence of bytes (such as a *bytes* object) containing subsequences that are expected to occur frequently in the data that is to be compressed. Those subsequences that are expected to be most common should come at the end of the dictionary.

Changed in version 3.3: Added the *zdict* parameter and keyword argument support.

zlib.crc32(*data*[, *value*])

Computes a CRC (Cyclic Redundancy Check) checksum of *data*. The result is an unsigned 32-bit integer. If *value* is present, it is used as the starting value of the checksum; otherwise, a default value of 0 is used. Passing in *value* allows computing a running checksum over the concatenation of several inputs. The algorithm is not cryptographically strong, and should not be used for authentication or digital signatures. Since the algorithm is designed for use as a checksum algorithm, it is not suitable for use as a general hash algorithm.

Changed in version 3.0: Always returns an unsigned value. To generate the same numeric value across all Python versions and platforms, use `crc32(data) & 0xffffffff`.

zlib.decompress(*data*, *wbits=MAX_WBITS*, *bufsize=DEF_BUF_SIZE*)

Decompresses the bytes in *data*, returning a bytes object containing the uncompressed data. The *wbits* parameter depends on the format of *data*, and is discussed further below. If *bufsize* is given, it is used as the initial size of the output buffer. Raises the *error* exception if any error occurs.

The *wbits* parameter controls the size of the history buffer (or "window size"), and what header and trailer format is expected. It is similar to the parameter for *compressobj()*, but accepts more ranges of values:

- +8 to +15: The base-two logarithm of the window size. The input must include a zlib header and trailer.
- 0: Automatically determine the window size from the zlib header. Only supported since zlib 1.2.3.5.
- −8 to −15: Uses the absolute value of *wbits* as the window size logarithm. The input must be a raw stream with no header or trailer.
- +24 to +31 = 16 + (8 to 15): Uses the low 4 bits of the value as the window size logarithm. The input must include a gzip header and trailer.
- +40 to +47 = 32 + (8 to 15): Uses the low 4 bits of the value as the window size logarithm, and automatically accepts either the zlib or gzip format.

When decompressing a stream, the window size must not be smaller than the size originally used to compress the stream; using a too-small value may result in an *error* exception. The default *wbits* value corresponds to the largest window size and requires a zlib header and trailer to be included.

bufsize is the initial size of the buffer used to hold decompressed data. If more space is required, the buffer size will be increased as needed, so you don't have to get this value exactly right; tuning it will only save a few calls to `malloc()`.

Changed in version 3.6: *wbits* and *bufsize* can be used as keyword arguments.

`zlib.decompressobj`(*wbits=MAX_WBITS*[, *zdict*])
Returns a decompression object, to be used for decompressing data streams that won't fit into memory at once.

The *wbits* parameter controls the size of the history buffer (or the "window size"), and what header and trailer format is expected. It has the same meaning as *described for decompress()*.

The *zdict* parameter specifies a predefined compression dictionary. If provided, this must be the same dictionary as was used by the compressor that produced the data that is to be decompressed.

Note: If *zdict* is a mutable object (such as a *bytearray*), you must not modify its contents between the call to *decompressobj()* and the first call to the decompressor's `decompress()` method.

Changed in version 3.3: Added the *zdict* parameter.

Compression objects support the following methods:

`Compress.compress`(*data*)
Compress *data*, returning a bytes object containing compressed data for at least part of the data in *data*. This data should be concatenated to the output produced by any preceding calls to the *compress()* method. Some input may be kept in internal buffers for later processing.

`Compress.flush`([*mode*])
All pending input is processed, and a bytes object containing the remaining compressed output is returned. *mode* can be selected from the constants `Z_NO_FLUSH`, `Z_PARTIAL_FLUSH`, `Z_SYNC_FLUSH`, `Z_FULL_FLUSH`, `Z_BLOCK` (zlib 1.2.3.4), or `Z_FINISH`, defaulting to `Z_FINISH`. Except `Z_FINISH`, all constants allow compressing further bytestrings of data, while `Z_FINISH` finishes the compressed stream and prevents compressing any more data. After calling *flush()* with *mode* set to `Z_FINISH`, the *compress()* method cannot be called again; the only realistic action is to delete the object.

`Compress.copy`()
Returns a copy of the compression object. This can be used to efficiently compress a set of data that share a common initial prefix.

Decompression objects support the following methods and attributes:

Decompress.**unused_data**
A bytes object which contains any bytes past the end of the compressed data. That is, this remains `b""` until the last byte that contains compression data is available. If the whole bytestring turned out to contain compressed data, this is `b""`, an empty bytes object.

Decompress.**unconsumed_tail**
A bytes object that contains any data that was not consumed by the last *decompress()* call because it exceeded the limit for the uncompressed data buffer. This data has not yet been seen by the zlib machinery, so you must feed it (possibly with further data concatenated to it) back to a subsequent *decompress()* method call in order to get correct output.

Decompress.**eof**
A boolean indicating whether the end of the compressed data stream has been reached.

This makes it possible to distinguish between a properly-formed compressed stream, and an incomplete or truncated one.

New in version 3.3.

Decompress.**decompress**(*data*, *max_length=0*)
Decompress *data*, returning a bytes object containing the uncompressed data corresponding to at least part of the data in *string*. This data should be concatenated to the output produced by any preceding calls to the *decompress()* method. Some of the input data may be preserved in internal buffers for later processing.

If the optional parameter *max_length* is non-zero then the return value will be no longer than *max_length*. This may mean that not all of the compressed input can be processed; and unconsumed data will be stored in the attribute *unconsumed_tail*. This bytestring must be passed to a subsequent call to *decompress()* if decompression is to continue. If *max_length* is zero then the whole input is decompressed, and *unconsumed_tail* is empty.

Changed in version 3.6: *max_length* can be used as a keyword argument.

Decompress.**flush**([*length*])
All pending input is processed, and a bytes object containing the remaining uncompressed output is returned. After calling *flush()*, the *decompress()* method cannot be called again; the only realistic action is to delete the object.

The optional parameter *length* sets the initial size of the output buffer.

Decompress.**copy**()
Returns a copy of the decompression object. This can be used to save the state of the decompressor midway through the data stream in order to speed up random seeks into the stream at a future point.

Information about the version of the zlib library in use is available through the following constants:

zlib.**ZLIB_VERSION**
The version string of the zlib library that was used for building the module. This may be different from the zlib library actually used at runtime, which is available as *ZLIB_RUNTIME_VERSION*.

zlib.**ZLIB_RUNTIME_VERSION**
The version string of the zlib library actually loaded by the interpreter.

New in version 3.3.

Module *gzip* Reading and writing **gzip**-format files.

http://www.zlib.net The zlib library home page.

http://www.zlib.net/manual.html The zlib manual explains the semantics and usage of the library's many functions.

13.2 gzip — Support for gzip files

Source code: Lib/gzip.py

This module provides a simple interface to compress and decompress files just like the GNU programs **gzip** and **gunzip** would.

The data compression is provided by the *zlib* module.

The *gzip* module provides the *GzipFile* class, as well as the *open()*, *compress()* and *decompress()* convenience functions. The *GzipFile* class reads and writes **gzip**-format files, automatically compressing or decompressing the data so that it looks like an ordinary *file object*.

Note that additional file formats which can be decompressed by the **gzip** and **gunzip** programs, such as those produced by **compress** and **pack**, are not supported by this module.

The module defines the following items:

gzip.open(*filename*, *mode='rb'*, *compresslevel=9*, *encoding=None*, *errors=None*, *newline=None*)
Open a gzip-compressed file in binary or text mode, returning a *file object*.

The *filename* argument can be an actual filename (a *str* or *bytes* object), or an existing file object to read from or write to.

The *mode* argument can be any of `'r'`, `'rb'`, `'a'`, `'ab'`, `'w'`, `'wb'`, `'x'` or `'xb'` for binary mode, or `'rt'`, `'at'`, `'wt'`, or `'xt'` for text mode. The default is `'rb'`.

The *compresslevel* argument is an integer from 0 to 9, as for the *GzipFile* constructor.

For binary mode, this function is equivalent to the *GzipFile* constructor: `GzipFile(filename, mode, compresslevel)`. In this case, the *encoding*, *errors* and *newline* arguments must not be provided.

For text mode, a *GzipFile* object is created, and wrapped in an *io.TextIOWrapper* instance with the specified encoding, error handling behavior, and line ending(s).

Changed in version 3.3: Added support for *filename* being a file object, support for text mode, and the *encoding*, *errors* and *newline* arguments.

Changed in version 3.4: Added support for the `'x'`, `'xb'` and `'xt'` modes.

Changed in version 3.6: Accepts a *path-like object*.

class gzip.GzipFile(*filename=None*, *mode=None*, *compresslevel=9*, *fileobj=None*, *mtime=None*)
Constructor for the *GzipFile* class, which simulates most of the methods of a *file object*, with the exception of the `truncate()` method. At least one of *fileobj* and *filename* must be given a non-trivial value.

The new class instance is based on *fileobj*, which can be a regular file, an *io.BytesIO* object, or any other object which simulates a file. It defaults to `None`, in which case *filename* is opened to provide a file object.

When *fileobj* is not `None`, the *filename* argument is only used to be included in the **gzip** file header, which may include the original filename of the uncompressed file. It defaults to the filename of *fileobj*, if discernible; otherwise, it defaults to the empty string, and in this case the original filename is not included in the header.

The *mode* argument can be any of `'r'`, `'rb'`, `'a'`, `'ab'`, `'w'`, `'wb'`, `'x'`, or `'xb'`, depending on whether the file will be read or written. The default is the mode of *fileobj* if discernible; otherwise, the default is `'rb'`.

Note that the file is always opened in binary mode. To open a compressed file in text mode, use *open()* (or wrap your *GzipFile* with an *io.TextIOWrapper*).

The *compresslevel* argument is an integer from `0` to `9` controlling the level of compression; `1` is fastest and produces the least compression, and `9` is slowest and produces the most compression. `0` is no compression. The default is `9`.

The *mtime* argument is an optional numeric timestamp to be written to the last modification time field in the stream when compressing. It should only be provided in compression mode. If omitted or `None`, the current time is used. See the *mtime* attribute for more details.

Calling a *GzipFile* object's `close()` method does not close *fileobj*, since you might wish to append more material after the compressed data. This also allows you to pass an *io.BytesIO* object opened for writing as *fileobj*, and retrieve the resulting memory buffer using the *io.BytesIO* object's *getvalue()* method.

GzipFile supports the *io.BufferedIOBase* interface, including iteration and the `with` statement. Only the `truncate()` method isn't implemented.

GzipFile also provides the following method and attribute:

peek(*n*)
Read *n* uncompressed bytes without advancing the file position. At most one single read on the compressed stream is done to satisfy the call. The number of bytes returned may be more or less than requested.

Note: While calling *peek()* does not change the file position of the *GzipFile*, it may change the position of the underlying file object (e.g. if the *GzipFile* was constructed with the *fileobj* parameter).

New in version 3.2.

mtime
When decompressing, the value of the last modification time field in the most recently read header may be read from this attribute, as an integer. The initial value before reading any headers is `None`.

All **gzip** compressed streams are required to contain this timestamp field. Some programs, such as **gunzip**, make use of the timestamp. The format is the same as the return value of *time.time()* and the *st_mtime* attribute of the object returned by *os.stat()*.

Changed in version 3.1: Support for the `with` statement was added, along with the *mtime* constructor argument and *mtime* attribute.

Changed in version 3.2: Support for zero-padded and unseekable files was added.

Changed in version 3.3: The *io.BufferedIOBase.read1()* method is now implemented.

Changed in version 3.4: Added support for the `'x'` and `'xb'` modes.

Changed in version 3.5: Added support for writing arbitrary *bytes-like objects*. The *read()* method now accepts an argument of `None`.

Changed in version 3.6: Accepts a *path-like object*.

gzip.compress(*data*, *compresslevel=9*)
Compress the *data*, returning a *bytes* object containing the compressed data. *compresslevel* has the same meaning as in the *GzipFile* constructor above.

New in version 3.2.

gzip.decompress(*data*)
Decompress the *data*, returning a *bytes* object containing the uncompressed data.

New in version 3.2.

13.2.1 Examples of usage

Example of how to read a compressed file:

```
import gzip
with gzip.open('/home/joe/file.txt.gz', 'rb') as f:
    file_content = f.read()
```

Example of how to create a compressed GZIP file:

```
import gzip
content = b"Lots of content here"
with gzip.open('/home/joe/file.txt.gz', 'wb') as f:
    f.write(content)
```

Example of how to GZIP compress an existing file:

```
import gzip
import shutil
with open('/home/joe/file.txt', 'rb') as f_in:
    with gzip.open('/home/joe/file.txt.gz', 'wb') as f_out:
        shutil.copyfileobj(f_in, f_out)
```

Example of how to GZIP compress a binary string:

```
import gzip
s_in = b"Lots of content here"
s_out = gzip.compress(s_in)
```

See also:

Module *zlib* The basic data compression module needed to support the **gzip** file format.

13.3 bz2 — Support for bzip2 compression

Source code: Lib/bz2.py

This module provides a comprehensive interface for compressing and decompressing data using the bzip2 compression algorithm.

The *bz2* module contains:

- The *open()* function and *BZ2File* class for reading and writing compressed files.
- The *BZ2Compressor* and *BZ2Decompressor* classes for incremental (de)compression.
- The *compress()* and *decompress()* functions for one-shot (de)compression.

All of the classes in this module may safely be accessed from multiple threads.

13.3.1 (De)compression of files

bz2.open(*filename*, *mode='r'*, *compresslevel=9*, *encoding=None*, *errors=None*, *newline=None*)
Open a bzip2-compressed file in binary or text mode, returning a *file object*.

As with the constructor for *BZ2File*, the *filename* argument can be an actual filename (a *str* or *bytes* object), or an existing file object to read from or write to.

The *mode* argument can be any of `'r'`, `'rb'`, `'w'`, `'wb'`, `'x'`, `'xb'`, `'a'` or `'ab'` for binary mode, or `'rt'`, `'wt'`, `'xt'`, or `'at'` for text mode. The default is `'rb'`.

The *compresslevel* argument is an integer from 1 to 9, as for the *BZ2File* constructor.

For binary mode, this function is equivalent to the *BZ2File* constructor: `BZ2File(filename, mode, compresslevel=compresslevel)`. In this case, the *encoding*, *errors* and *newline* arguments must not be provided.

For text mode, a *BZ2File* object is created, and wrapped in an *io.TextIOWrapper* instance with the specified encoding, error handling behavior, and line ending(s).

New in version 3.3.

Changed in version 3.4: The `'x'` (exclusive creation) mode was added.

Changed in version 3.6: Accepts a *path-like object*.

class bz2.BZ2File(*filename*, *mode='r'*, *buffering=None*, *compresslevel=9*)

Open a bzip2-compressed file in binary mode.

If *filename* is a *str* or *bytes* object, open the named file directly. Otherwise, *filename* should be a *file object*, which will be used to read or write the compressed data.

The *mode* argument can be either `'r'` for reading (default), `'w'` for overwriting, `'x'` for exclusive creation, or `'a'` for appending. These can equivalently be given as `'rb'`, `'wb'`, `'xb'` and `'ab'` respectively.

If *filename* is a file object (rather than an actual file name), a mode of `'w'` does not truncate the file, and is instead equivalent to `'a'`.

The *buffering* argument is ignored. Its use is deprecated.

If *mode* is `'w'` or `'a'`, *compresslevel* can be a number between `1` and `9` specifying the level of compression: `1` produces the least compression, and `9` (default) produces the most compression.

If *mode* is `'r'`, the input file may be the concatenation of multiple compressed streams.

BZ2File provides all of the members specified by the *io.BufferedIOBase*, except for `detach()` and `truncate()`. Iteration and the `with` statement are supported.

BZ2File also provides the following method:

peek(*[n]*)

Return buffered data without advancing the file position. At least one byte of data will be returned (unless at EOF). The exact number of bytes returned is unspecified.

Note: While calling *peek()* does not change the file position of the *BZ2File*, it may change the position of the underlying file object (e.g. if the *BZ2File* was constructed by passing a file object for *filename*).

New in version 3.3.

Changed in version 3.1: Support for the `with` statement was added.

Changed in version 3.3: The `fileno()`, `readable()`, `seekable()`, `writable()`, `read1()` and `readinto()` methods were added.

Changed in version 3.3: Support was added for *filename* being a *file object* instead of an actual filename.

Changed in version 3.3: The `'a'` (append) mode was added, along with support for reading multi-stream files.

Changed in version 3.4: The `'x'` (exclusive creation) mode was added.

Changed in version 3.5: The *read()* method now accepts an argument of `None`.

Changed in version 3.6: Accepts a *path-like object*.

13.3.2 Incremental (de)compression

`class bz2.BZ2Compressor(`*compresslevel=9*`)`

Create a new compressor object. This object may be used to compress data incrementally. For one-shot compression, use the *compress()* function instead.

compresslevel, if given, must be a number between `1` and `9`. The default is `9`.

`compress(`*data*`)`

Provide data to the compressor object. Returns a chunk of compressed data if possible, or an empty byte string otherwise.

When you have finished providing data to the compressor, call the *flush()* method to finish the compression process.

`flush()`

Finish the compression process. Returns the compressed data left in internal buffers.

The compressor object may not be used after this method has been called.

`class bz2.BZ2Decompressor`

Create a new decompressor object. This object may be used to decompress data incrementally. For one-shot compression, use the *decompress()* function instead.

Note: This class does not transparently handle inputs containing multiple compressed streams, unlike *decompress()* and *BZ2File*. If you need to decompress a multi-stream input with *BZ2Decompressor*, you must use a new decompressor for each stream.

`decompress(`*data*, *max_length=-1*`)`

Decompress *data* (a *bytes-like object*), returning uncompressed data as bytes. Some of *data* may be buffered internally, for use in later calls to *decompress()*. The returned data should be concatenated with the output of any previous calls to *decompress()*.

If *max_length* is nonnegative, returns at most *max_length* bytes of decompressed data. If this limit is reached and further output can be produced, the *needs_input* attribute will be set to `False`. In this case, the next call to *decompress()* may provide *data* as `b''` to obtain more of the output.

If all of the input data was decompressed and returned (either because this was less than *max_length* bytes, or because *max_length* was negative), the *needs_input* attribute will be set to `True`.

Attempting to decompress data after the end of stream is reached raises an *EOFError*. Any data found after the end of the stream is ignored and saved in the *unused_data* attribute.

Changed in version 3.5: Added the *max_length* parameter.

`eof`

`True` if the end-of-stream marker has been reached.

New in version 3.3.

`unused_data`

Data found after the end of the compressed stream.

If this attribute is accessed before the end of the stream has been reached, its value will be `b''`.

needs_input
`False` if the *decompress()* method can provide more decompressed data before requiring new uncompressed input.

New in version 3.5.

13.3.3 One-shot (de)compression

bz2.compress(*data*, *compresslevel=9*)
Compress *data*.

compresslevel, if given, must be a number between `1` and `9`. The default is `9`.

For incremental compression, use a *BZ2Compressor* instead.

bz2.decompress(*data*)
Decompress *data*.

If *data* is the concatenation of multiple compressed streams, decompress all of the streams.

For incremental decompression, use a *BZ2Decompressor* instead.

Changed in version 3.3: Support for multi-stream inputs was added.

13.4 `lzma` — Compression using the LZMA algorithm

New in version 3.3.

Source code: Lib/lzma.py

This module provides classes and convenience functions for compressing and decompressing data using the LZMA compression algorithm. Also included is a file interface supporting the `.xz` and legacy `.lzma` file formats used by the **xz** utility, as well as raw compressed streams.

The interface provided by this module is very similar to that of the *bz2* module. However, note that *LZMAFile* is *not* thread-safe, unlike *bz2.BZ2File*, so if you need to use a single *LZMAFile* instance from multiple threads, it is necessary to protect it with a lock.

exception lzma.LZMAError
This exception is raised when an error occurs during compression or decompression, or while initializing the compressor/decompressor state.

13.4.1 Reading and writing compressed files

lzma.open(*filename*, *mode="rb"*, ***, *format=None*, *check=-1*, *preset=None*, *filters=None*, *encoding=None*, *errors=None*, *newline=None*)
Open an LZMA-compressed file in binary or text mode, returning a *file object*.

The *filename* argument can be either an actual file name (given as a *str*, *bytes* or *path-like* object), in which case the named file is opened, or it can be an existing file object to read from or write to.

The *mode* argument can be any of `"r"`, `"rb"`, `"w"`, `"wb"`, `"x"`, `"xb"`, `"a"` or `"ab"` for binary mode, or `"rt"`, `"wt"`, `"xt"`, or `"at"` for text mode. The default is `"rb"`.

When opening a file for reading, the *format* and *filters* arguments have the same meanings as for *LZMADecompressor*. In this case, the *check* and *preset* arguments should not be used.

When opening a file for writing, the *format*, *check*, *preset* and *filters* arguments have the same meanings as for *LZMACompressor*.

For binary mode, this function is equivalent to the *LZMAFile* constructor: `LZMAFile(filename, mode, ...)`. In this case, the *encoding*, *errors* and *newline* arguments must not be provided.

For text mode, a *LZMAFile* object is created, and wrapped in an *io.TextIOWrapper* instance with the specified encoding, error handling behavior, and line ending(s).

Changed in version 3.4: Added support for the `"x"`, `"xb"` and `"xt"` modes.

Changed in version 3.6: Accepts a *path-like object*.

class lzma.LZMAFile(*filename=None*, *mode="r"*, ***, *format=None*, *check=-1*, *preset=None*, *filters=None*)

Open an LZMA-compressed file in binary mode.

An *LZMAFile* can wrap an already-open *file object*, or operate directly on a named file. The *filename* argument specifies either the file object to wrap, or the name of the file to open (as a *str*, *bytes* or *path-like* object). When wrapping an existing file object, the wrapped file will not be closed when the *LZMAFile* is closed.

The *mode* argument can be either `"r"` for reading (default), `"w"` for overwriting, `"x"` for exclusive creation, or `"a"` for appending. These can equivalently be given as `"rb"`, `"wb"`, `"xb"` and `"ab"` respectively.

If *filename* is a file object (rather than an actual file name), a mode of `"w"` does not truncate the file, and is instead equivalent to `"a"`.

When opening a file for reading, the input file may be the concatenation of multiple separate compressed streams. These are transparently decoded as a single logical stream.

When opening a file for reading, the *format* and *filters* arguments have the same meanings as for *LZMADecompressor*. In this case, the *check* and *preset* arguments should not be used.

When opening a file for writing, the *format*, *check*, *preset* and *filters* arguments have the same meanings as for *LZMACompressor*.

LZMAFile supports all the members specified by *io.BufferedIOBase*, except for `detach()` and `truncate()`. Iteration and the `with` statement are supported.

The following method is also provided:

peek(*size=-1*)

Return buffered data without advancing the file position. At least one byte of data will be returned, unless EOF has been reached. The exact number of bytes returned is unspecified (the *size* argument is ignored).

Note: While calling *peek()* does not change the file position of the *LZMAFile*, it may change the position of the underlying file object (e.g. if the *LZMAFile* was constructed by passing a file object for *filename*).

Changed in version 3.4: Added support for the `"x"` and `"xb"` modes.

Changed in version 3.5: The *read()* method now accepts an argument of `None`.

Changed in version 3.6: Accepts a *path-like object*.

13.4.2 Compressing and decompressing data in memory

class lzma.LZMACompressor(*format=FORMAT_XZ*, *check=-1*, *preset=None*, *filters=None*)

Create a compressor object, which can be used to compress data incrementally.

For a more convenient way of compressing a single chunk of data, see *compress()*.

The *format* argument specifies what container format should be used. Possible values are:

- **FORMAT_XZ: The .xz container format.** This is the default format.
- **FORMAT_ALONE: The legacy .lzma container format.** This format is more limited than .xz – it does not support integrity checks or multiple filters.
- **FORMAT_RAW: A raw data stream, not using any container format.** This format specifier does not support integrity checks, and requires that you always specify a custom filter chain (for both compression and decompression). Additionally, data compressed in this manner cannot be decompressed using FORMAT_AUTO (see *LZMADecompressor*).

The *check* argument specifies the type of integrity check to include in the compressed data. This check is used when decompressing, to ensure that the data has not been corrupted. Possible values are:

- CHECK_NONE: No integrity check. This is the default (and the only acceptable value) for FORMAT_ALONE and FORMAT_RAW.
- CHECK_CRC32: 32-bit Cyclic Redundancy Check.
- CHECK_CRC64: 64-bit Cyclic Redundancy Check. This is the default for FORMAT_XZ.
- CHECK_SHA256: 256-bit Secure Hash Algorithm.

If the specified check is not supported, an *LZMAError* is raised.

The compression settings can be specified either as a preset compression level (with the *preset* argument), or in detail as a custom filter chain (with the *filters* argument).

The *preset* argument (if provided) should be an integer between 0 and 9 (inclusive), optionally OR-ed with the constant PRESET_EXTREME. If neither *preset* nor *filters* are given, the default behavior is to use PRESET_DEFAULT (preset level 6). Higher presets produce smaller output, but make the compression process slower.

Note: In addition to being more CPU-intensive, compression with higher presets also requires much more memory (and produces output that needs more memory to decompress). With preset 9 for example, the overhead for an *LZMACompressor* object can be as high as 800 MiB. For this reason, it is generally best to stick with the default preset.

The *filters* argument (if provided) should be a filter chain specifier. See *Specifying custom filter chains* for details.

compress(*data*)
Compress *data* (a *bytes* object), returning a *bytes* object containing compressed data for at least part of the input. Some of *data* may be buffered internally, for use in later calls to *compress()* and *flush()*. The returned data should be concatenated with the output of any previous calls to *compress()*.

flush()
Finish the compression process, returning a *bytes* object containing any data stored in the compressor's internal buffers.

The compressor cannot be used after this method has been called.

class lzma.LZMADecompressor(*format=FORMAT_AUTO*, *memlimit=None*, *filters=None*)
Create a decompressor object, which can be used to decompress data incrementally.

For a more convenient way of decompressing an entire compressed stream at once, see *decompress()*.

The *format* argument specifies the container format that should be used. The default is FORMAT_AUTO, which can decompress both .xz and .lzma files. Other possible values are FORMAT_XZ, FORMAT_ALONE, and FORMAT_RAW.

The *memlimit* argument specifies a limit (in bytes) on the amount of memory that the decompressor can use. When this argument is used, decompression will fail with an *LZMAError* if it is not possible to decompress the input within the given memory limit.

The *filters* argument specifies the filter chain that was used to create the stream being decompressed. This argument is required if *format* is `FORMAT_RAW`, but should not be used for other formats. See *Specifying custom filter chains* for more information about filter chains.

Note: This class does not transparently handle inputs containing multiple compressed streams, unlike *decompress()* and *LZMAFile*. To decompress a multi-stream input with *LZMADecompressor*, you must create a new decompressor for each stream.

---

decompress(*data*, *max_length=-1*)

Decompress *data* (a *bytes-like object*), returning uncompressed data as bytes. Some of *data* may be buffered internally, for use in later calls to *decompress()*. The returned data should be concatenated with the output of any previous calls to *decompress()*.

If *max_length* is nonnegative, returns at most *max_length* bytes of decompressed data. If this limit is reached and further output can be produced, the *needs_input* attribute will be set to `False`. In this case, the next call to *decompress()* may provide *data* as `b''` to obtain more of the output.

If all of the input data was decompressed and returned (either because this was less than *max_length* bytes, or because *max_length* was negative), the *needs_input* attribute will be set to `True`.

Attempting to decompress data after the end of stream is reached raises an *EOFError*. Any data found after the end of the stream is ignored and saved in the *unused_data* attribute.

Changed in version 3.5: Added the *max_length* parameter.

check

The ID of the integrity check used by the input stream. This may be `CHECK_UNKNOWN` until enough of the input has been decoded to determine what integrity check it uses.

eof

`True` if the end-of-stream marker has been reached.

unused_data

Data found after the end of the compressed stream.

Before the end of the stream is reached, this will be `b""`.

needs_input

`False` if the *decompress()* method can provide more decompressed data before requiring new uncompressed input.

New in version 3.5.

lzma.**compress**(*data*, *format=FORMAT_XZ*, *check=-1*, *preset=None*, *filters=None*)

Compress *data* (a *bytes* object), returning the compressed data as a *bytes* object.

See *LZMACompressor* above for a description of the *format*, *check*, *preset* and *filters* arguments.

lzma.**decompress**(*data*, *format=FORMAT_AUTO*, *memlimit=None*, *filters=None*)

Decompress *data* (a *bytes* object), returning the uncompressed data as a *bytes* object.

If *data* is the concatenation of multiple distinct compressed streams, decompress all of these streams, and return the concatenation of the results.

See *LZMADecompressor* above for a description of the *format*, *memlimit* and *filters* arguments.

13.4.3 Miscellaneous

`lzma.is_check_supported(`*check*`)`
Returns true if the given integrity check is supported on this system.

`CHECK_NONE` and `CHECK_CRC32` are always supported. `CHECK_CRC64` and `CHECK_SHA256` may be unavailable if you are using a version of `liblzma` that was compiled with a limited feature set.

13.4.4 Specifying custom filter chains

A filter chain specifier is a sequence of dictionaries, where each dictionary contains the ID and options for a single filter. Each dictionary must contain the key `"id"`, and may contain additional keys to specify filter-dependent options. Valid filter IDs are as follows:

- **Compression filters:**
  - `FILTER_LZMA1` (for use with `FORMAT_ALONE`)
  - `FILTER_LZMA2` (for use with `FORMAT_XZ` and `FORMAT_RAW`)
- **Delta filter:**
  - `FILTER_DELTA`
- **Branch-Call-Jump (BCJ) filters:**
  - `FILTER_X86`
  - `FILTER_IA64`
  - `FILTER_ARM`
  - `FILTER_ARMTHUMB`
  - `FILTER_POWERPC`
  - `FILTER_SPARC`

A filter chain can consist of up to 4 filters, and cannot be empty. The last filter in the chain must be a compression filter, and any other filters must be delta or BCJ filters.

Compression filters support the following options (specified as additional entries in the dictionary representing the filter):

- `preset`: A compression preset to use as a source of default values for options that are not specified explicitly.
- `dict_size`: Dictionary size in bytes. This should be between 4 KiB and 1.5 GiB (inclusive).
- `lc`: Number of literal context bits.
- `lp`: Number of literal position bits. The sum `lc + lp` must be at most 4.
- `pb`: Number of position bits; must be at most 4.
- `mode`: `MODE_FAST` or `MODE_NORMAL`.
- `nice_len`: What should be considered a "nice length" for a match. This should be 273 or less.
- `mf`: What match finder to use – `MF_HC3`, `MF_HC4`, `MF_BT2`, `MF_BT3`, or `MF_BT4`.
- `depth`: Maximum search depth used by match finder. 0 (default) means to select automatically based on other filter options.

The delta filter stores the differences between bytes, producing more repetitive input for the compressor in certain circumstances. It supports one option, `dist`. This indicates the distance between bytes to be subtracted. The default is 1, i.e. take the differences between adjacent bytes.

The BCJ filters are intended to be applied to machine code. They convert relative branches, calls and jumps in the code to use absolute addressing, with the aim of increasing the redundancy that can be exploited by the compressor. These filters support one option, `start_offset`. This specifies the address that should be mapped to the beginning of the input data. The default is 0.

13.4.5 Examples

Reading in a compressed file:

```
import lzma
with lzma.open("file.xz") as f:
    file_content = f.read()
```

Creating a compressed file:

```
import lzma
data = b"Insert Data Here"
with lzma.open("file.xz", "w") as f:
    f.write(data)
```

Compressing data in memory:

```
import lzma
data_in = b"Insert Data Here"
data_out = lzma.compress(data_in)
```

Incremental compression:

```
import lzma
lzc = lzma.LZMACompressor()
out1 = lzc.compress(b"Some data\n")
out2 = lzc.compress(b"Another piece of data\n")
out3 = lzc.compress(b"Even more data\n")
out4 = lzc.flush()
# Concatenate all the partial results:
result = b"".join([out1, out2, out3, out4])
```

Writing compressed data to an already-open file:

```
import lzma
with open("file.xz", "wb") as f:
    f.write(b"This data will not be compressed\n")
    with lzma.open(f, "w") as lzf:
        lzf.write(b"This *will* be compressed\n")
    f.write(b"Not compressed\n")
```

Creating a compressed file using a custom filter chain:

```
import lzma
my_filters = [
    {"id": lzma.FILTER_DELTA, "dist": 5},
    {"id": lzma.FILTER_LZMA2, "preset": 7 | lzma.PRESET_EXTREME},
]
with lzma.open("file.xz", "w", filters=my_filters) as f:
    f.write(b"blah blah blah")
```

13.5 zipfile — Work with ZIP archives

Source code: Lib/zipfile.py

The ZIP file format is a common archive and compression standard. This module provides tools to create, read, write, append, and list a ZIP file. Any advanced use of this module will require an understanding of the format, as defined in PKZIP Application Note.

This module does not currently handle multi-disk ZIP files. It can handle ZIP files that use the ZIP64 extensions (that is ZIP files that are more than 4 GiB in size). It supports decryption of encrypted files in ZIP archives, but it currently cannot create an encrypted file. Decryption is extremely slow as it is implemented in native Python rather than C.

The module defines the following items:

exception zipfile.BadZipFile
The error raised for bad ZIP files.

New in version 3.2.

exception zipfile.BadZipfile
Alias of *BadZipFile*, for compatibility with older Python versions.

Deprecated since version 3.2.

exception zipfile.LargeZipFile
The error raised when a ZIP file would require ZIP64 functionality but that has not been enabled.

class zipfile.ZipFile
The class for reading and writing ZIP files. See section *ZipFile Objects* for constructor details.

class zipfile.PyZipFile
Class for creating ZIP archives containing Python libraries.

class zipfile.ZipInfo(*filename='NoName'*, *date_time=(1980, 1, 1, 0, 0, 0)*)
Class used to represent information about a member of an archive. Instances of this class are returned by the *getinfo()* and *infolist()* methods of *ZipFile* objects. Most users of the *zipfile* module will not need to create these, but only use those created by this module. *filename* should be the full name of the archive member, and *date_time* should be a tuple containing six fields which describe the time of the last modification to the file; the fields are described in section *ZipInfo Objects*.

zipfile.is_zipfile(*filename*)
Returns `True` if *filename* is a valid ZIP file based on its magic number, otherwise returns `False`. *filename* may be a file or file-like object too.

Changed in version 3.1: Support for file and file-like objects.

zipfile.ZIP_STORED
The numeric constant for an uncompressed archive member.

zipfile.ZIP_DEFLATED
The numeric constant for the usual ZIP compression method. This requires the *zlib* module.

zipfile.ZIP_BZIP2
The numeric constant for the BZIP2 compression method. This requires the *bz2* module.

New in version 3.3.

zipfile.ZIP_LZMA
The numeric constant for the LZMA compression method. This requires the *lzma* module.

New in version 3.3.

Note: The ZIP file format specification has included support for bzip2 compression since 2001, and for LZMA compression since 2006. However, some tools (including older Python releases) do not support these compression methods, and may either refuse to process the ZIP file altogether, or fail to extract individual files.

See also:

PKZIP Application Note Documentation on the ZIP file format by Phil Katz, the creator of the format and algorithms used.

Info-ZIP Home Page Information about the Info-ZIP project's ZIP archive programs and development libraries.

13.5.1 ZipFile Objects

class zipfile.ZipFile(*file*, *mode='r'*, *compression=ZIP_STORED*, *allowZip64=True*, *compresslevel=None*)

Open a ZIP file, where *file* can be a path to a file (a string), a file-like object or a *path-like object*.

The *mode* parameter should be `'r'` to read an existing file, `'w'` to truncate and write a new file, `'a'` to append to an existing file, or `'x'` to exclusively create and write a new file. If *mode* is `'x'` and *file* refers to an existing file, a *FileExistsError* will be raised. If *mode* is `'a'` and *file* refers to an existing ZIP file, then additional files are added to it. If *file* does not refer to a ZIP file, then a new ZIP archive is appended to the file. This is meant for adding a ZIP archive to another file (such as `python.exe`). If *mode* is `'a'` and the file does not exist at all, it is created. If *mode* is `'r'` or `'a'`, the file should be seekable.

compression is the ZIP compression method to use when writing the archive, and should be *ZIP_STORED*, *ZIP_DEFLATED*, *ZIP_BZIP2* or *ZIP_LZMA*; unrecognized values will cause *NotImplementedError* to be raised. If *ZIP_DEFLATED*, *ZIP_BZIP2* or *ZIP_LZMA* is specified but the corresponding module (*zlib*, *bz2* or *lzma*) is not available, *RuntimeError* is raised. The default is *ZIP_STORED*.

If *allowZip64* is `True` (the default) zipfile will create ZIP files that use the ZIP64 extensions when the zipfile is larger than 4 GiB. If it is `false` *zipfile* will raise an exception when the ZIP file would require ZIP64 extensions.

The *compresslevel* parameter controls the compression level to use when writing files to the archive. When using *ZIP_STORED* or *ZIP_LZMA* it has no effect. When using *ZIP_DEFLATED* integers `0` through `9` are accepted (see *zlib* for more information). When using *ZIP_BZIP2* integers `1` through `9` are accepted (see *bz2* for more information).

If the file is created with mode `'w'`, `'x'` or `'a'` and then *closed* without adding any files to the archive, the appropriate ZIP structures for an empty archive will be written to the file.

ZipFile is also a context manager and therefore supports the `with` statement. In the example, *myzip* is closed after the `with` statement's suite is finished—even if an exception occurs:

```
with ZipFile('spam.zip', 'w') as myzip:
    myzip.write('eggs.txt')
```

New in version 3.2: Added the ability to use *ZipFile* as a context manager.

Changed in version 3.3: Added support for *bzip2* and *lzma* compression.

Changed in version 3.4: ZIP64 extensions are enabled by default.

Changed in version 3.5: Added support for writing to unseekable streams. Added support for the `'x'` mode.

Changed in version 3.6: Previously, a plain *RuntimeError* was raised for unrecognized compression values.

Changed in version 3.6.2: The *file* parameter accepts a *path-like object*.

Changed in version 3.7: Add the *compresslevel* parameter.

ZipFile.close()
Close the archive file. You must call *close()* before exiting your program or essential records will not be written.

ZipFile.getinfo(*name*)
Return a *ZipInfo* object with information about the archive member *name*. Calling *getinfo()* for a name not currently contained in the archive will raise a *KeyError*.

ZipFile.infolist()
Return a list containing a *ZipInfo* object for each member of the archive. The objects are in the same order as their entries in the actual ZIP file on disk if an existing archive was opened.

ZipFile.namelist()
Return a list of archive members by name.

ZipFile.open(*name*, *mode='r'*, *pwd=None*, ***, *force_zip64=False*)
Access a member of the archive as a binary file-like object. *name* can be either the name of a file within the archive or a *ZipInfo* object. The *mode* parameter, if included, must be `'r'` (the default) or `'w'`. *pwd* is the password used to decrypt encrypted ZIP files.

open() is also a context manager and therefore supports the `with` statement:

```
with ZipFile('spam.zip') as myzip:
    with myzip.open('eggs.txt') as myfile:
        print(myfile.read())
```

With *mode* `'r'` the file-like object (`ZipExtFile`) is read-only and provides the following methods: *read()*, *readline()*, *readlines()*, *seek()*, *tell()*, `__iter__()`, *__next__()*. These objects can operate independently of the ZipFile.

With `mode='w'`, a writable file handle is returned, which supports the *write()* method. While a writable file handle is open, attempting to read or write other files in the ZIP file will raise a *ValueError*.

When writing a file, if the file size is not known in advance but may exceed 2 GiB, pass `force_zip64=True` to ensure that the header format is capable of supporting large files. If the file size is known in advance, construct a *ZipInfo* object with *file_size* set, and use that as the *name* parameter.

Note: The *open()*, *read()* and *extract()* methods can take a filename or a *ZipInfo* object. You will appreciate this when trying to read a ZIP file that contains members with duplicate names.

Changed in version 3.6: Removed support of `mode='U'`. Use *io.TextIOWrapper* for reading compressed text files in *universal newlines* mode.

Changed in version 3.6: *open()* can now be used to write files into the archive with the `mode='w'` option.

Changed in version 3.6: Calling *open()* on a closed ZipFile will raise a *ValueError*. Previously, a *RuntimeError* was raised.

ZipFile.extract(*member*, *path=None*, *pwd=None*)
Extract a member from the archive to the current working directory; *member* must be its full name or a *ZipInfo* object. Its file information is extracted as accurately as possible. *path* specifies a different

directory to extract to. *member* can be a filename or a *ZipInfo* object. *pwd* is the password used for encrypted files.

Returns the normalized path created (a directory or new file).

Note: If a member filename is an absolute path, a drive/UNC sharepoint and leading (back)slashes will be stripped, e.g.: `///foo/bar` becomes `foo/bar` on Unix, and `C:\foo\bar` becomes `foo\bar` on Windows. And all `".."` components in a member filename will be removed, e.g.: `../../foo../../ba..r` becomes `foo../ba..r`. On Windows illegal characters (`:`, `<`, `>`, `|`, `"`, `?`, and `*`) replaced by underscore (`_`).

Changed in version 3.6: Calling *extract()* on a closed ZipFile will raise a *ValueError*. Previously, a *RuntimeError* was raised.

Changed in version 3.6.2: The *path* parameter accepts a *path-like object*.

ZipFile.extractall(*path=None*, *members=None*, *pwd=None*)

Extract all members from the archive to the current working directory. *path* specifies a different directory to extract to. *members* is optional and must be a subset of the list returned by *namelist()*. *pwd* is the password used for encrypted files.

> **Warning:** Never extract archives from untrusted sources without prior inspection. It is possible that files are created outside of *path*, e.g. members that have absolute filenames starting with `"/"` or filenames with two dots `".."`. This module attempts to prevent that. See *extract()* note.

Changed in version 3.6: Calling *extractall()* on a closed ZipFile will raise a *ValueError*. Previously, a *RuntimeError* was raised.

Changed in version 3.6.2: The *path* parameter accepts a *path-like object*.

ZipFile.printdir()

Print a table of contents for the archive to `sys.stdout`.

ZipFile.setpassword(*pwd*)

Set *pwd* as default password to extract encrypted files.

ZipFile.read(*name*, *pwd=None*)

Return the bytes of the file *name* in the archive. *name* is the name of the file in the archive, or a *ZipInfo* object. The archive must be open for read or append. *pwd* is the password used for encrypted files and, if specified, it will override the default password set with *setpassword()*. Calling *read()* on a ZipFile that uses a compression method other than *ZIP_STORED*, *ZIP_DEFLATED*, *ZIP_BZIP2* or *ZIP_LZMA* will raise a *NotImplementedError*. An error will also be raised if the corresponding compression module is not available.

Changed in version 3.6: Calling *read()* on a closed ZipFile will raise a *ValueError*. Previously, a *RuntimeError* was raised.

ZipFile.testzip()

Read all the files in the archive and check their CRC's and file headers. Return the name of the first bad file, or else return `None`.

Changed in version 3.6: Calling `testfile()` on a closed ZipFile will raise a *ValueError*. Previously, a *RuntimeError* was raised.

ZipFile.write(*filename*, *arcname=None*, *compress_type=None*, *compresslevel=None*)

Write the file named *filename* to the archive, giving it the archive name *arcname* (by default, this will be the same as *filename*, but without a drive letter and with leading path separators removed). If given, *compress_type* overrides the value given for the *compression* parameter to the constructor for

the new entry. Similarly, *compresslevel* will override the constructor if given. The archive must be open with mode `'w'`, `'x'` or `'a'`.

Note: There is no official file name encoding for ZIP files. If you have unicode file names, you must convert them to byte strings in your desired encoding before passing them to *write()*. WinZip interprets all file names as encoded in CP437, also known as DOS Latin.

Note: Archive names should be relative to the archive root, that is, they should not start with a path separator.

Note: If `arcname` (or `filename`, if `arcname` is not given) contains a null byte, the name of the file in the archive will be truncated at the null byte.

Changed in version 3.6: Calling *write()* on a ZipFile created with mode `'r'` or a closed ZipFile will raise a *ValueError*. Previously, a *RuntimeError* was raised.

`ZipFile.writestr`(*zinfo_or_arcname*, *data*, *compress_type=None*, *compresslevel=None*)

Write the string *data* to the archive; *zinfo_or_arcname* is either the file name it will be given in the archive, or a *ZipInfo* instance. If it's an instance, at least the filename, date, and time must be given. If it's a name, the date and time is set to the current date and time. The archive must be opened with mode `'w'`, `'x'` or `'a'`.

If given, *compress_type* overrides the value given for the *compression* parameter to the constructor for the new entry, or in the *zinfo_or_arcname* (if that is a *ZipInfo* instance). Similarly, *compresslevel* will override the constructor if given.

Note: When passing a *ZipInfo* instance as the *zinfo_or_arcname* parameter, the compression method used will be that specified in the *compress_type* member of the given *ZipInfo* instance. By default, the *ZipInfo* constructor sets this member to *ZIP_STORED*.

Changed in version 3.2: The *compress_type* argument.

Changed in version 3.6: Calling *writestr()* on a ZipFile created with mode `'r'` or a closed ZipFile will raise a *ValueError*. Previously, a *RuntimeError* was raised.

The following data attributes are also available:

`ZipFile.filename`

Name of the ZIP file.

`ZipFile.debug`

The level of debug output to use. This may be set from `0` (the default, no output) to `3` (the most output). Debugging information is written to `sys.stdout`.

`ZipFile.comment`

The comment text associated with the ZIP file. If assigning a comment to a *ZipFile* instance created with mode `'w'`, `'x'` or `'a'`, this should be a string no longer than 65535 bytes. Comments longer than this will be truncated in the written archive when *close()* is called.

13.5.2 PyZipFile Objects

The *PyZipFile* constructor takes the same parameters as the *ZipFile* constructor, and one additional parameter, *optimize*.

class zipfile.PyZipFile(*file*, *mode='r'*, *compression=ZIP_STORED*, *allowZip64=True*, *optimize=-1*)

New in version 3.2: The *optimize* parameter.

Changed in version 3.4: ZIP64 extensions are enabled by default.

Instances have one method in addition to those of *ZipFile* objects:

writepy(*pathname*, *basename=''*, *filterfunc=None*)

Search for files `*.py` and add the corresponding file to the archive.

If the *optimize* parameter to *PyZipFile* was not given or `-1`, the corresponding file is a `*.pyc` file, compiling if necessary.

If the *optimize* parameter to *PyZipFile* was `0`, `1` or `2`, only files with that optimization level (see *compile()*) are added to the archive, compiling if necessary.

If *pathname* is a file, the filename must end with `.py`, and just the (corresponding `*.pyc`) file is added at the top level (no path information). If *pathname* is a file that does not end with `.py`, a *RuntimeError* will be raised. If it is a directory, and the directory is not a package directory, then all the files `*.pyc` are added at the top level. If the directory is a package directory, then all `*.pyc` are added under the package name as a file path, and if any subdirectories are package directories, all of these are added recursively in sorted order.

basename is intended for internal use only.

filterfunc, if given, must be a function taking a single string argument. It will be passed each path (including each individual full file path) before it is added to the archive. If *filterfunc* returns a false value, the path will not be added, and if it is a directory its contents will be ignored. For example, if our test files are all either in `test` directories or start with the string `test_`, we can use a *filterfunc* to exclude them:

```
>>> zf = PyZipFile('myprog.zip')
>>> def notests(s):
...     fn = os.path.basename(s)
...     return (not (fn == 'test' or fn.startswith('test_')))
>>> zf.writepy('myprog', filterfunc=notests)
```

The *writepy()* method makes archives with file names like this:

```
string.pyc                  # Top level name
test/__init__.pyc           # Package directory
test/testall.pyc            # Module test.testall
test/bogus/__init__.pyc     # Subpackage directory
test/bogus/myfile.pyc       # Submodule test.bogus.myfile
```

New in version 3.4: The *filterfunc* parameter.

Changed in version 3.6.2: The *pathname* parameter accepts a *path-like object*.

Changed in version 3.7: Recursion sorts directory entries.

13.5.3 ZipInfo Objects

Instances of the *ZipInfo* class are returned by the *getinfo()* and *infolist()* methods of *ZipFile* objects. Each object stores information about a single member of the ZIP archive.

There is one classmethod to make a *ZipInfo* instance for a filesystem file:

classmethod ZipInfo.from_file(*filename*, *arcname=None*)

Construct a *ZipInfo* instance for a file on the filesystem, in preparation for adding it to a zip file.

filename should be the path to a file or directory on the filesystem.

If *arcname* is specified, it is used as the name within the archive. If *arcname* is not specified, the name will be the same as *filename*, but with any drive letter and leading path separators removed.

New in version 3.6.

Changed in version 3.6.2: The *filename* parameter accepts a *path-like object*.

Instances have the following methods and attributes:

`ZipInfo.is_dir()`
Return `True` if this archive member is a directory.

This uses the entry's name: directories should always end with `/`.

New in version 3.6.

`ZipInfo.filename`
Name of the file in the archive.

`ZipInfo.date_time`
The time and date of the last modification to the archive member. This is a tuple of six values:

Index	Value
0	Year (>= 1980)
1	Month (one-based)
2	Day of month (one-based)
3	Hours (zero-based)
4	Minutes (zero-based)
5	Seconds (zero-based)

Note: The ZIP file format does not support timestamps before 1980.

`ZipInfo.compress_type`
Type of compression for the archive member.

`ZipInfo.comment`
Comment for the individual archive member.

`ZipInfo.extra`
Expansion field data. The PKZIP Application Note contains some comments on the internal structure of the data contained in this string.

`ZipInfo.create_system`
System which created ZIP archive.

`ZipInfo.create_version`
PKZIP version which created ZIP archive.

`ZipInfo.extract_version`
PKZIP version needed to extract archive.

`ZipInfo.reserved`
Must be zero.

`ZipInfo.flag_bits`
ZIP flag bits.

`ZipInfo.volume`
Volume number of file header.

ZipInfo.**internal_attr**
Internal attributes.

ZipInfo.**external_attr**
External file attributes.

ZipInfo.**header_offset**
Byte offset to the file header.

ZipInfo.**CRC**
CRC-32 of the uncompressed file.

ZipInfo.**compress_size**
Size of the compressed data.

ZipInfo.**file_size**
Size of the uncompressed file.

13.5.4 Command-Line Interface

The *zipfile* module provides a simple command-line interface to interact with ZIP archives.

If you want to create a new ZIP archive, specify its name after the `-c` option and then list the filename(s) that should be included:

```
$ python -m zipfile -c monty.zip spam.txt eggs.txt
```

Passing a directory is also acceptable:

```
$ python -m zipfile -c monty.zip life-of-brian_1979/
```

If you want to extract a ZIP archive into the specified directory, use the `-e` option:

```
$ python -m zipfile -e monty.zip target-dir/
```

For a list of the files in a ZIP archive, use the `-l` option:

```
$ python -m zipfile -l monty.zip
```

Command-line options

-l <zipfile>
--list <zipfile>
List files in a zipfile.

-c <zipfile> <source1> ... <sourceN>
--create <zipfile> <source1> ... <sourceN>
Create zipfile from source files.

-e <zipfile> <output_dir>
--extract <zipfile> <output_dir>
Extract zipfile into target directory.

-t <zipfile>
--test <zipfile>
Test whether the zipfile is valid or not.

13.6 tarfile — Read and write tar archive files

Source code: Lib/tarfile.py

The *tarfile* module makes it possible to read and write tar archives, including those using gzip, bz2 and lzma compression. Use the *zipfile* module to read or write `.zip` files, or the higher-level functions in *shutil*.

Some facts and figures:

- reads and writes *gzip*, *bz2* and *lzma* compressed archives if the respective modules are available.
- read/write support for the POSIX.1-1988 (ustar) format.
- read/write support for the GNU tar format including *longname* and *longlink* extensions, read-only support for all variants of the *sparse* extension including restoration of sparse files.
- read/write support for the POSIX.1-2001 (pax) format.
- handles directories, regular files, hardlinks, symbolic links, fifos, character devices and block devices and is able to acquire and restore file information like timestamp, access permissions and owner.

Changed in version 3.3: Added support for *lzma* compression.

`tarfile.open`(*name=None*, *mode='r'*, *fileobj=None*, *bufsize=10240*, ***kwargs*)

Return a *TarFile* object for the pathname *name*. For detailed information on *TarFile* objects and the keyword arguments that are allowed, see *TarFile Objects*.

mode has to be a string of the form `'filemode[:compression]'`, it defaults to `'r'`. Here is a full list of mode combinations:

mode	action
`'r'` or `'r:*'`	Open for reading with transparent compression (recommended).
`'r:'`	Open for reading exclusively without compression.
`'r:gz'`	Open for reading with gzip compression.
`'r:bz2'`	Open for reading with bzip2 compression.
`'r:xz'`	Open for reading with lzma compression.
`'x'` or `'x:'`	Create a tarfile exclusively without compression. Raise an *FileExistsError* exception if it already exists.
`'x:gz'`	Create a tarfile with gzip compression. Raise an *FileExistsError* exception if it already exists.
`'x:bz2'`	Create a tarfile with bzip2 compression. Raise an *FileExistsError* exception if it already exists.
`'x:xz'`	Create a tarfile with lzma compression. Raise an *FileExistsError* exception if it already exists.
`'a'` or `'a:'`	Open for appending with no compression. The file is created if it does not exist.
`'w'` or `'w:'`	Open for uncompressed writing.
`'w:gz'`	Open for gzip compressed writing.
`'w:bz2'`	Open for bzip2 compressed writing.
`'w:xz'`	Open for lzma compressed writing.

Note that `'a:gz'`, `'a:bz2'` or `'a:xz'` is not possible. If *mode* is not suitable to open a certain (compressed) file for reading, *ReadError* is raised. Use *mode* `'r'` to avoid this. If a compression method is not supported, *CompressionError* is raised.

If *fileobj* is specified, it is used as an alternative to a *file object* opened in binary mode for *name*. It is supposed to be at position 0.

For modes `'w:gz'`, `'r:gz'`, `'w:bz2'`, `'r:bz2'`, `'x:gz'`, `'x:bz2'`, *tarfile.open()* accepts the keyword argument *compresslevel* (default `9`) to specify the compression level of the file.

For special purposes, there is a second format for *mode*: `'filemode|[compression]'`. *tarfile.open()* will return a *TarFile* object that processes its data as a stream of blocks. No random seeking will be done on the file. If given, *fileobj* may be any object that has a `read()` or `write()` method (depending on the *mode*). *bufsize* specifies the blocksize and defaults to `20 * 512` bytes. Use this variant in combination with e.g. `sys.stdin`, a socket *file object* or a tape device. However, such a *TarFile* object is limited in that it does not allow random access, see *Examples*. The currently possible modes:

Mode	Action
`'r|*'`	Open a *stream* of tar blocks for reading with transparent compression.
`'r|'`	Open a *stream* of uncompressed tar blocks for reading.
`'r|gz'`	Open a gzip compressed *stream* for reading.
`'r|bz2'`	Open a bzip2 compressed *stream* for reading.
`'r|xz'`	Open an lzma compressed *stream* for reading.
`'w|'`	Open an uncompressed *stream* for writing.
`'w|gz'`	Open a gzip compressed *stream* for writing.
`'w|bz2'`	Open a bzip2 compressed *stream* for writing.
`'w|xz'`	Open an lzma compressed *stream* for writing.

Changed in version 3.5: The `'x'` (exclusive creation) mode was added.

Changed in version 3.6: The *name* parameter accepts a *path-like object*.

class tarfile.TarFile
Class for reading and writing tar archives. Do not use this class directly: use *tarfile.open()* instead. See *TarFile Objects*.

tarfile.is_tarfile(*name*)
Return *True* if *name* is a tar archive file, that the *tarfile* module can read.

The *tarfile* module defines the following exceptions:

exception tarfile.TarError
Base class for all *tarfile* exceptions.

exception tarfile.ReadError
Is raised when a tar archive is opened, that either cannot be handled by the *tarfile* module or is somehow invalid.

exception tarfile.CompressionError
Is raised when a compression method is not supported or when the data cannot be decoded properly.

exception tarfile.StreamError
Is raised for the limitations that are typical for stream-like *TarFile* objects.

exception tarfile.ExtractError
Is raised for *non-fatal* errors when using *TarFile.extract()*, but only if `TarFile.errorlevel== 2`.

exception tarfile.HeaderError
Is raised by *TarInfo.frombuf()* if the buffer it gets is invalid.

The following constants are available at the module level:

tarfile.ENCODING
The default character encoding: `'utf-8'` on Windows, the value returned by *sys.getfilesystemencoding()* otherwise.

Each of the following constants defines a tar archive format that the *tarfile* module is able to create. See section *Supported tar formats* for details.

`tarfile.USTAR_FORMAT`
POSIX.1-1988 (ustar) format.

`tarfile.GNU_FORMAT`
GNU tar format.

`tarfile.PAX_FORMAT`
POSIX.1-2001 (pax) format.

`tarfile.DEFAULT_FORMAT`
The default format for creating archives. This is currently *GNU_FORMAT*.

Module *zipfile* Documentation of the *zipfile* standard module.

Archiving operations Documentation of the higher-level archiving facilities provided by the standard *shutil* module.

GNU tar manual, Basic Tar Format Documentation for tar archive files, including GNU tar extensions.

13.6.1 TarFile Objects

The *TarFile* object provides an interface to a tar archive. A tar archive is a sequence of blocks. An archive member (a stored file) is made up of a header block followed by data blocks. It is possible to store a file in a tar archive several times. Each archive member is represented by a *TarInfo* object, see *TarInfo Objects* for details.

A *TarFile* object can be used as a context manager in a `with` statement. It will automatically be closed when the block is completed. Please note that in the event of an exception an archive opened for writing will not be finalized; only the internally used file object will be closed. See the *Examples* section for a use case.

New in version 3.2: Added support for the context management protocol.

`class tarfile.TarFile(`*name=None*, *mode='r'*, *fileobj=None*, *format=DEFAULT_FORMAT*, *tarinfo=TarInfo*, *dereference=False*, *ignore_zeros=False*, *encoding=ENCODING*, *errors='surrogateescape'*, *pax_headers=None*, *debug=0*, *errorlevel=0*`)`

All following arguments are optional and can be accessed as instance attributes as well.

name is the pathname of the archive. *name* may be a *path-like object*. It can be omitted if *fileobj* is given. In this case, the file object's `name` attribute is used if it exists.

mode is either `'r'` to read from an existing archive, `'a'` to append data to an existing file, `'w'` to create a new file overwriting an existing one, or `'x'` to create a new file only if it does not already exist.

If *fileobj* is given, it is used for reading or writing data. If it can be determined, *mode* is overridden by *fileobj*'s mode. *fileobj* will be used from position 0.

Note: *fileobj* is not closed, when *TarFile* is closed.

---

format controls the archive format. It must be one of the constants *USTAR_FORMAT*, *GNU_FORMAT* or *PAX_FORMAT* that are defined at module level.

The *tarinfo* argument can be used to replace the default *TarInfo* class with a different one.

If *dereference* is *False*, add symbolic and hard links to the archive. If it is *True*, add the content of the target files to the archive. This has no effect on systems that do not support symbolic links.

If *ignore_zeros* is *False*, treat an empty block as the end of the archive. If it is *True*, skip empty (and invalid) blocks and try to get as many members as possible. This is only useful for reading concatenated or damaged archives.

debug can be set from `0` (no debug messages) up to `3` (all debug messages). The messages are written to `sys.stderr`.

If *errorlevel* is `0`, all errors are ignored when using *TarFile.extract()*. Nevertheless, they appear as error messages in the debug output, when debugging is enabled. If `1`, all *fatal* errors are raised as *OSError* exceptions. If `2`, all *non-fatal* errors are raised as *TarError* exceptions as well.

The *encoding* and *errors* arguments define the character encoding to be used for reading or writing the archive and how conversion errors are going to be handled. The default settings will work for most users. See section *Unicode issues* for in-depth information.

The *pax_headers* argument is an optional dictionary of strings which will be added as a pax global header if *format* is *PAX_FORMAT*.

Changed in version 3.2: Use `'surrogateescape'` as the default for the *errors* argument.

Changed in version 3.5: The `'x'` (exclusive creation) mode was added.

Changed in version 3.6: The *name* parameter accepts a *path-like object*.

classmethod `TarFile.open`(...)
Alternative constructor. The *tarfile.open()* function is actually a shortcut to this classmethod.

`TarFile.getmember`(*name*)
Return a *TarInfo* object for member *name*. If *name* can not be found in the archive, *KeyError* is raised.

Note: If a member occurs more than once in the archive, its last occurrence is assumed to be the most up-to-date version.

`TarFile.getmembers`()
Return the members of the archive as a list of *TarInfo* objects. The list has the same order as the members in the archive.

`TarFile.getnames`()
Return the members as a list of their names. It has the same order as the list returned by *getmembers()*.

`TarFile.list`(*verbose=True*, ***, *members=None*)
Print a table of contents to `sys.stdout`. If *verbose* is *False*, only the names of the members are printed. If it is *True*, output similar to that of `ls -l` is produced. If optional *members* is given, it must be a subset of the list returned by *getmembers()*.

Changed in version 3.5: Added the *members* parameter.

`TarFile.next`()
Return the next member of the archive as a *TarInfo* object, when *TarFile* is opened for reading. Return *None* if there is no more available.

`TarFile.extractall`(*path="."*, *members=None*, ***, *numeric_owner=False*)
Extract all members from the archive to the current working directory or directory *path*. If optional *members* is given, it must be a subset of the list returned by *getmembers()*. Directory information like owner, modification time and permissions are set after all members have been extracted. This is done to work around two problems: A directory's modification time is reset each time a file is created in it. And, if a directory's permissions do not allow writing, extracting files to it will fail.

If *numeric_owner* is *True*, the uid and gid numbers from the tarfile are used to set the owner/group for the extracted files. Otherwise, the named values from the tarfile are used.

> **Warning:** Never extract archives from untrusted sources without prior inspection. It is possible that files are created outside of *path*, e.g. members that have absolute filenames starting with `"/"` or filenames with two dots `".."`.

Changed in version 3.5: Added the *numeric_owner* parameter.

Changed in version 3.6: The *path* parameter accepts a *path-like object*.

TarFile.extract(*member*, *path=""*, *set_attrs=True*, ***, *numeric_owner=False*)
Extract a member from the archive to the current working directory, using its full name. Its file information is extracted as accurately as possible. *member* may be a filename or a *TarInfo* object. You can specify a different directory using *path*. *path* may be a *path-like object*. File attributes (owner, mtime, mode) are set unless *set_attrs* is false.

If *numeric_owner* is *True*, the uid and gid numbers from the tarfile are used to set the owner/group for the extracted files. Otherwise, the named values from the tarfile are used.

Note: The *extract()* method does not take care of several extraction issues. In most cases you should consider using the *extractall()* method.

> **Warning:** See the warning for *extractall()*.

Changed in version 3.2: Added the *set_attrs* parameter.

Changed in version 3.5: Added the *numeric_owner* parameter.

Changed in version 3.6: The *path* parameter accepts a *path-like object*.

TarFile.extractfile(*member*)
Extract a member from the archive as a file object. *member* may be a filename or a *TarInfo* object. If *member* is a regular file or a link, an *io.BufferedReader* object is returned. Otherwise, *None* is returned.

Changed in version 3.3: Return an *io.BufferedReader* object.

TarFile.add(*name*, *arcname=None*, *recursive=True*, ***, *filter=None*)
Add the file *name* to the archive. *name* may be any type of file (directory, fifo, symbolic link, etc.). If given, *arcname* specifies an alternative name for the file in the archive. Directories are added recursively by default. This can be avoided by setting *recursive* to *False*. Recursion adds entries in sorted order. If *filter* is given, it should be a function that takes a *TarInfo* object argument and returns the changed *TarInfo* object. If it instead returns *None* the *TarInfo* object will be excluded from the archive. See *Examples* for an example.

Changed in version 3.2: Added the *filter* parameter.

Changed in version 3.7: Recursion adds entries in sorted order.

TarFile.addfile(*tarinfo*, *fileobj=None*)
Add the *TarInfo* object *tarinfo* to the archive. If *fileobj* is given, it should be a *binary file*, and `tarinfo.size` bytes are read from it and added to the archive. You can create *TarInfo* objects directly, or by using *gettarinfo()*.

TarFile.gettarinfo(*name=None*, *arcname=None*, *fileobj=None*)
Create a *TarInfo* object from the result of *os.stat()* or equivalent on an existing file. The file is

either named by *name*, or specified as a *file object* *fileobj* with a file descriptor. *name* may be a *path-like object*. If given, *arcname* specifies an alternative name for the file in the archive, otherwise, the name is taken from *fileobj*'s *name* attribute, or the *name* argument. The name should be a text string.

You can modify some of the *TarInfo*'s attributes before you add it using *addfile()*. If the file object is not an ordinary file object positioned at the beginning of the file, attributes such as *size* may need modifying. This is the case for objects such as *GzipFile*. The *name* may also be modified, in which case *arcname* could be a dummy string.

Changed in version 3.6: The *name* parameter accepts a *path-like object*.

TarFile.close()
Close the *TarFile*. In write mode, two finishing zero blocks are appended to the archive.

TarFile.pax_headers
A dictionary containing key-value pairs of pax global headers.

13.6.2 TarInfo Objects

A *TarInfo* object represents one member in a *TarFile*. Aside from storing all required attributes of a file (like file type, size, time, permissions, owner etc.), it provides some useful methods to determine its type. It does *not* contain the file's data itself.

TarInfo objects are returned by *TarFile*'s methods **getmember()**, **getmembers()** and **gettarinfo()**.

class tarfile.TarInfo(*name=""*)
Create a *TarInfo* object.

classmethod TarInfo.frombuf(*buf*, *encoding*, *errors*)
Create and return a *TarInfo* object from string buffer *buf*.

Raises *HeaderError* if the buffer is invalid.

classmethod TarInfo.fromtarfile(*tarfile*)
Read the next member from the *TarFile* object *tarfile* and return it as a *TarInfo* object.

TarInfo.tobuf(*format=DEFAULT_FORMAT*, *encoding=ENCODING*, *errors='surrogateescape'*)
Create a string buffer from a *TarInfo* object. For information on the arguments see the constructor of the *TarFile* class.

Changed in version 3.2: Use **'surrogateescape'** as the default for the *errors* argument.

A **TarInfo** object has the following public data attributes:

TarInfo.name
Name of the archive member.

TarInfo.size
Size in bytes.

TarInfo.mtime
Time of last modification.

TarInfo.mode
Permission bits.

TarInfo.type
File type. *type* is usually one of these constants: **REGTYPE**, **AREGTYPE**, **LNKTYPE**, **SYMTYPE**, **DIRTYPE**, **FIFOTYPE**, **CONTTYPE**, **CHRTYPE**, **BLKTYPE**, **GNUTYPE_SPARSE**. To determine the type of a *TarInfo* object more conveniently, use the **is*()** methods below.

TarInfo.linkname
Name of the target file name, which is only present in *TarInfo* objects of type **LNKTYPE** and **SYMTYPE**.

TarInfo.uid
User ID of the user who originally stored this member.

TarInfo.gid
Group ID of the user who originally stored this member.

TarInfo.uname
User name.

TarInfo.gname
Group name.

TarInfo.pax_headers
A dictionary containing key-value pairs of an associated pax extended header.

A *TarInfo* object also provides some convenient query methods:

TarInfo.isfile()
Return *True* if the Tarinfo object is a regular file.

TarInfo.isreg()
Same as *isfile()*.

TarInfo.isdir()
Return *True* if it is a directory.

TarInfo.issym()
Return *True* if it is a symbolic link.

TarInfo.islnk()
Return *True* if it is a hard link.

TarInfo.ischr()
Return *True* if it is a character device.

TarInfo.isblk()
Return *True* if it is a block device.

TarInfo.isfifo()
Return *True* if it is a FIFO.

TarInfo.isdev()
Return *True* if it is one of character device, block device or FIFO.

13.6.3 Command-Line Interface

New in version 3.4.

The *tarfile* module provides a simple command-line interface to interact with tar archives.

If you want to create a new tar archive, specify its name after the `-c` option and then list the filename(s) that should be included:

```
$ python -m tarfile -c monty.tar  spam.txt eggs.txt
```

Passing a directory is also acceptable:

```
$ python -m tarfile -c monty.tar life-of-brian_1979/
```

If you want to extract a tar archive into the current directory, use the `-e` option:

```
$ python -m tarfile -e monty.tar
```

You can also extract a tar archive into a different directory by passing the directory's name:

```
$ python -m tarfile -e monty.tar  other-dir/
```

For a list of the files in a tar archive, use the `-l` option:

```
$ python -m tarfile -l monty.tar
```

Command-line options

-l <tarfile>
--list <tarfile>
List files in a tarfile.

-c <tarfile> <source1> ... <sourceN>
--create <tarfile> <source1> ... <sourceN>
Create tarfile from source files.

-e <tarfile> [<output_dir>]
--extract <tarfile> [<output_dir>]
Extract tarfile into the current directory if *output_dir* is not specified.

-t <tarfile>
--test <tarfile>
Test whether the tarfile is valid or not.

-v, --verbose
Verbose output.

13.6.4 Examples

How to extract an entire tar archive to the current working directory:

```
import tarfile
tar = tarfile.open("sample.tar.gz")
tar.extractall()
tar.close()
```

How to extract a subset of a tar archive with *TarFile.extractall()* using a generator function instead of a list:

```
import os
import tarfile

def py_files(members):
    for tarinfo in members:
        if os.path.splitext(tarinfo.name)[1] == ".py":
            yield tarinfo

tar = tarfile.open("sample.tar.gz")
tar.extractall(members=py_files(tar))
tar.close()
```

How to create an uncompressed tar archive from a list of filenames:

```
import tarfile
tar = tarfile.open("sample.tar", "w")
for name in ["foo", "bar", "quux"]:
```

(continues on next page)

(continued from previous page)

```
    tar.add(name)
tar.close()
```

The same example using the `with` statement:

```
import tarfile
with tarfile.open("sample.tar", "w") as tar:
    for name in ["foo", "bar", "quux"]:
        tar.add(name)
```

How to read a gzip compressed tar archive and display some member information:

```
import tarfile
tar = tarfile.open("sample.tar.gz", "r:gz")
for tarinfo in tar:
    print(tarinfo.name, "is", tarinfo.size, "bytes in size and is", end="")
    if tarinfo.isreg():
        print("a regular file.")
    elif tarinfo.isdir():
        print("a directory.")
    else:
        print("something else.")
tar.close()
```

How to create an archive and reset the user information using the *filter* parameter in *TarFile.add()*:

```
import tarfile
def reset(tarinfo):
    tarinfo.uid = tarinfo.gid = 0
    tarinfo.uname = tarinfo.gname = "root"
    return tarinfo
tar = tarfile.open("sample.tar.gz", "w:gz")
tar.add("foo", filter=reset)
tar.close()
```

13.6.5 Supported tar formats

There are three tar formats that can be created with the *tarfile* module:

- The POSIX.1-1988 ustar format (*USTAR_FORMAT*). It supports filenames up to a length of at best 256 characters and linknames up to 100 characters. The maximum file size is 8 GiB. This is an old and limited but widely supported format.
- The GNU tar format (*GNU_FORMAT*). It supports long filenames and linknames, files bigger than 8 GiB and sparse files. It is the de facto standard on GNU/Linux systems. *tarfile* fully supports the GNU tar extensions for long names, sparse file support is read-only.
- The POSIX.1-2001 pax format (*PAX_FORMAT*). It is the most flexible format with virtually no limits. It supports long filenames and linknames, large files and stores pathnames in a portable way. However, not all tar implementations today are able to handle pax archives properly.

  The *pax* format is an extension to the existing *ustar* format. It uses extra headers for information that cannot be stored otherwise. There are two flavours of pax headers: Extended headers only affect the subsequent file header, global headers are valid for the complete archive and affect all following files. All the data in a pax header is encoded in *UTF-8* for portability reasons.

There are some more variants of the tar format which can be read, but not created:

- The ancient V7 format. This is the first tar format from Unix Seventh Edition, storing only regular files and directories. Names must not be longer than 100 characters, there is no user/group name information. Some archives have miscalculated header checksums in case of fields with non-ASCII characters.
- The SunOS tar extended format. This format is a variant of the POSIX.1-2001 pax format, but is not compatible.

13.6.6 Unicode issues

The tar format was originally conceived to make backups on tape drives with the main focus on preserving file system information. Nowadays tar archives are commonly used for file distribution and exchanging archives over networks. One problem of the original format (which is the basis of all other formats) is that there is no concept of supporting different character encodings. For example, an ordinary tar archive created on a *UTF-8* system cannot be read correctly on a *Latin-1* system if it contains non-*ASCII* characters. Textual metadata (like filenames, linknames, user/group names) will appear damaged. Unfortunately, there is no way to autodetect the encoding of an archive. The pax format was designed to solve this problem. It stores non-ASCII metadata using the universal character encoding *UTF-8*.

The details of character conversion in *tarfile* are controlled by the *encoding* and *errors* keyword arguments of the *TarFile* class.

encoding defines the character encoding to use for the metadata in the archive. The default value is *sys.getfilesystemencoding()* or `'ascii'` as a fallback. Depending on whether the archive is read or written, the metadata must be either decoded or encoded. If *encoding* is not set appropriately, this conversion may fail.

The *errors* argument defines how characters are treated that cannot be converted. Possible values are listed in section *Error Handlers*. The default scheme is `'surrogateescape'` which Python also uses for its file system calls, see *File Names, Command Line Arguments, and Environment Variables*.

In case of *PAX_FORMAT* archives, *encoding* is generally not needed because all the metadata is stored using *UTF-8*. *encoding* is only used in the rare cases when binary pax headers are decoded or when strings with surrogate characters are stored.

CHAPTER

FOURTEEN

FILE FORMATS

The modules described in this chapter parse various miscellaneous file formats that aren't markup languages and are not related to e-mail.

14.1 csv — CSV File Reading and Writing

Source code: Lib/csv.py

The so-called CSV (Comma Separated Values) format is the most common import and export format for spreadsheets and databases. CSV format was used for many years prior to attempts to describe the format in a standardized way in **RFC 4180**. The lack of a well-defined standard means that subtle differences often exist in the data produced and consumed by different applications. These differences can make it annoying to process CSV files from multiple sources. Still, while the delimiters and quoting characters vary, the overall format is similar enough that it is possible to write a single module which can efficiently manipulate such data, hiding the details of reading and writing the data from the programmer.

The *csv* module implements classes to read and write tabular data in CSV format. It allows programmers to say, "write this data in the format preferred by Excel," or "read data from this file which was generated by Excel," without knowing the precise details of the CSV format used by Excel. Programmers can also describe the CSV formats understood by other applications or define their own special-purpose CSV formats.

The *csv* module's *reader* and *writer* objects read and write sequences. Programmers can also read and write data in dictionary form using the *DictReader* and *DictWriter* classes.

See also:

PEP 305 - CSV File API The Python Enhancement Proposal which proposed this addition to Python.

14.1.1 Module Contents

The *csv* module defines the following functions:

`csv.reader(`*csvfile*, *dialect='excel'*, ***fmtparams*`)`

Return a reader object which will iterate over lines in the given *csvfile*. *csvfile* can be any object which supports the *iterator* protocol and returns a string each time its `__next__()` method is called — *file objects* and list objects are both suitable. If *csvfile* is a file object, it should be opened with `newline=''`.[1] An optional *dialect* parameter can be given which is used to define a set of parameters specific to a particular CSV dialect. It may be an instance of a subclass of the *Dialect* class or one of the strings returned by the *list_dialects()* function. The other optional *fmtparams* keyword

[1] If `newline=''` is not specified, newlines embedded inside quoted fields will not be interpreted correctly, and on platforms that use `\r\n` linendings on write an extra `\r` will be added. It should always be safe to specify `newline=''`, since the csv module does its own (*universal*) newline handling.

arguments can be given to override individual formatting parameters in the current dialect. For full details about the dialect and formatting parameters, see section *Dialects and Formatting Parameters*.

Each row read from the csv file is returned as a list of strings. No automatic data type conversion is performed unless the `QUOTE_NONNUMERIC` format option is specified (in which case unquoted fields are transformed into floats).

A short usage example:

```
>>> import csv
>>> with open('eggs.csv', newline='') as csvfile:
...     spamreader = csv.reader(csvfile, delimiter=' ', quotechar='|')
...     for row in spamreader:
...         print(', '.join(row))
Spam, Spam, Spam, Spam, Spam, Baked Beans
Spam, Lovely Spam, Wonderful Spam
```

csv.writer(*csvfile*, *dialect='excel'*, ***fmtparams*)

Return a writer object responsible for converting the user's data into delimited strings on the given file-like object. *csvfile* can be any object with a `write()` method. If *csvfile* is a file object, it should be opened with `newline=''`[1]. An optional *dialect* parameter can be given which is used to define a set of parameters specific to a particular CSV dialect. It may be an instance of a subclass of the *Dialect* class or one of the strings returned by the *list_dialects()* function. The other optional *fmtparams* keyword arguments can be given to override individual formatting parameters in the current dialect. For full details about the dialect and formatting parameters, see section *Dialects and Formatting Parameters*. To make it as easy as possible to interface with modules which implement the DB API, the value *None* is written as the empty string. While this isn't a reversible transformation, it makes it easier to dump SQL NULL data values to CSV files without preprocessing the data returned from a `cursor.fetch*` call. All other non-string data are stringified with *str()* before being written.

A short usage example:

```
import csv
with open('eggs.csv', 'w', newline='') as csvfile:
    spamwriter = csv.writer(csvfile, delimiter=' ',
                            quotechar='|', quoting=csv.QUOTE_MINIMAL)
    spamwriter.writerow(['Spam'] * 5 + ['Baked Beans'])
    spamwriter.writerow(['Spam', 'Lovely Spam', 'Wonderful Spam'])
```

csv.register_dialect(*name*[, *dialect*[, ***fmtparams*]])

Associate *dialect* with *name*. *name* must be a string. The dialect can be specified either by passing a sub-class of *Dialect*, or by *fmtparams* keyword arguments, or both, with keyword arguments overriding parameters of the dialect. For full details about the dialect and formatting parameters, see section *Dialects and Formatting Parameters*.

csv.unregister_dialect(*name*)

Delete the dialect associated with *name* from the dialect registry. An *Error* is raised if *name* is not a registered dialect name.

csv.get_dialect(*name*)

Return the dialect associated with *name*. An *Error* is raised if *name* is not a registered dialect name. This function returns an immutable *Dialect*.

csv.list_dialects()

Return the names of all registered dialects.

csv.field_size_limit([*new_limit*])

Returns the current maximum field size allowed by the parser. If *new_limit* is given, this becomes the new limit.

The *csv* module defines the following classes:

class csv.DictReader(*f*, *fieldnames=None*, *restkey=None*, *restval=None*, *dialect='excel'*, **args*, ***kwds*)

Create an object that operates like a regular reader but maps the information in each row to an *OrderedDict* whose keys are given by the optional *fieldnames* parameter.

The *fieldnames* parameter is a *sequence*. If *fieldnames* is omitted, the values in the first row of file *f* will be used as the fieldnames. Regardless of how the fieldnames are determined, the ordered dictionary preserves their original ordering.

If a row has more fields than fieldnames, the remaining data is put in a list and stored with the fieldname specified by *restkey* (which defaults to `None`). If a non-blank row has fewer fields than fieldnames, the missing values are filled-in with `None`.

All other optional or keyword arguments are passed to the underlying *reader* instance.

Changed in version 3.6: Returned rows are now of type `OrderedDict`.

A short usage example:

```
>>> import csv
>>> with open('names.csv', newline='') as csvfile:
...     reader = csv.DictReader(csvfile)
...     for row in reader:
...         print(row['first_name'], row['last_name'])
...
Eric Idle
John Cleese

>>> print(row)
OrderedDict([('first_name', 'John'), ('last_name', 'Cleese')])
```

class csv.DictWriter(*f*, *fieldnames*, *restval=''*, *extrasaction='raise'*, *dialect='excel'*, **args*, ***kwds*)

Create an object which operates like a regular writer but maps dictionaries onto output rows. The *fieldnames* parameter is a *sequence* of keys that identify the order in which values in the dictionary passed to the `writerow()` method are written to file *f*. The optional *restval* parameter specifies the value to be written if the dictionary is missing a key in *fieldnames*. If the dictionary passed to the `writerow()` method contains a key not found in *fieldnames*, the optional *extrasaction* parameter indicates what action to take. If it is set to `'raise'`, the default value, a *ValueError* is raised. If it is set to `'ignore'`, extra values in the dictionary are ignored. Any other optional or keyword arguments are passed to the underlying *writer* instance.

Note that unlike the *DictReader* class, the *fieldnames* parameter of the *DictWriter* class is not optional.

A short usage example:

```
import csv

with open('names.csv', 'w', newline='') as csvfile:
    fieldnames = ['first_name', 'last_name']
    writer = csv.DictWriter(csvfile, fieldnames=fieldnames)

    writer.writeheader()
    writer.writerow({'first_name': 'Baked', 'last_name': 'Beans'})
    writer.writerow({'first_name': 'Lovely', 'last_name': 'Spam'})
    writer.writerow({'first_name': 'Wonderful', 'last_name': 'Spam'})
```

class csv.Dialect

The *Dialect* class is a container class relied on primarily for its attributes, which are used to define

the parameters for a specific *reader* or *writer* instance.

class csv.excel
The *excel* class defines the usual properties of an Excel-generated CSV file. It is registered with the dialect name 'excel'.

class csv.excel_tab
The *excel_tab* class defines the usual properties of an Excel-generated TAB-delimited file. It is registered with the dialect name 'excel-tab'.

class csv.unix_dialect
The *unix_dialect* class defines the usual properties of a CSV file generated on UNIX systems, i.e. using '\n' as line terminator and quoting all fields. It is registered with the dialect name 'unix'.

New in version 3.2.

class csv.Sniffer
The *Sniffer* class is used to deduce the format of a CSV file.

The *Sniffer* class provides two methods:

sniff(*sample*, *delimiters=None*)
Analyze the given *sample* and return a *Dialect* subclass reflecting the parameters found. If the optional *delimiters* parameter is given, it is interpreted as a string containing possible valid delimiter characters.

has_header(*sample*)
Analyze the sample text (presumed to be in CSV format) and return *True* if the first row appears to be a series of column headers.

An example for *Sniffer* use:

```
with open('example.csv', newline='') as csvfile:
    dialect = csv.Sniffer().sniff(csvfile.read(1024))
    csvfile.seek(0)
    reader = csv.reader(csvfile, dialect)
    # ... process CSV file contents here ...
```

The *csv* module defines the following constants:

csv.QUOTE_ALL
Instructs *writer* objects to quote all fields.

csv.QUOTE_MINIMAL
Instructs *writer* objects to only quote those fields which contain special characters such as *delimiter*, *quotechar* or any of the characters in *lineterminator*.

csv.QUOTE_NONNUMERIC
Instructs *writer* objects to quote all non-numeric fields.

Instructs the reader to convert all non-quoted fields to type *float*.

csv.QUOTE_NONE
Instructs *writer* objects to never quote fields. When the current *delimiter* occurs in output data it is preceded by the current *escapechar* character. If *escapechar* is not set, the writer will raise *Error* if any characters that require escaping are encountered.

Instructs *reader* to perform no special processing of quote characters.

The *csv* module defines the following exception:

exception csv.Error
Raised by any of the functions when an error is detected.

14.1.2 Dialects and Formatting Parameters

To make it easier to specify the format of input and output records, specific formatting parameters are grouped together into dialects. A dialect is a subclass of the *Dialect* class having a set of specific methods and a single `validate()` method. When creating *reader* or *writer* objects, the programmer can specify a string or a subclass of the *Dialect* class as the dialect parameter. In addition to, or instead of, the *dialect* parameter, the programmer can also specify individual formatting parameters, which have the same names as the attributes defined below for the *Dialect* class.

Dialects support the following attributes:

Dialect.delimiter
A one-character string used to separate fields. It defaults to `','`.

Dialect.doublequote
Controls how instances of *quotechar* appearing inside a field should themselves be quoted. When *True*, the character is doubled. When *False*, the *escapechar* is used as a prefix to the *quotechar*. It defaults to *True*.

On output, if *doublequote* is *False* and no *escapechar* is set, *Error* is raised if a *quotechar* is found in a field.

Dialect.escapechar
A one-character string used by the writer to escape the *delimiter* if *quoting* is set to *QUOTE_NONE* and the *quotechar* if *doublequote* is *False*. On reading, the *escapechar* removes any special meaning from the following character. It defaults to *None*, which disables escaping.

Dialect.lineterminator
The string used to terminate lines produced by the *writer*. It defaults to `'\r\n'`.

Note: The *reader* is hard-coded to recognise either `'\r'` or `'\n'` as end-of-line, and ignores *lineterminator*. This behavior may change in the future.

Dialect.quotechar
A one-character string used to quote fields containing special characters, such as the *delimiter* or *quotechar*, or which contain new-line characters. It defaults to `'"'`.

Dialect.quoting
Controls when quotes should be generated by the writer and recognised by the reader. It can take on any of the `QUOTE_*` constants (see section *Module Contents*) and defaults to *QUOTE_MINIMAL*.

Dialect.skipinitialspace
When *True*, whitespace immediately following the *delimiter* is ignored. The default is *False*.

Dialect.strict
When `True`, raise exception *Error* on bad CSV input. The default is `False`.

14.1.3 Reader Objects

Reader objects (*DictReader* instances and objects returned by the *reader()* function) have the following public methods:

csvreader.__next__()
Return the next row of the reader's iterable object as a list (if the object was returned from *reader()*) or a dict (if it is a *DictReader* instance), parsed according to the current dialect. Usually you should call this as `next(reader)`.

Reader objects have the following public attributes:

csvreader.dialect
A read-only description of the dialect in use by the parser.

csvreader.line_num
The number of lines read from the source iterator. This is not the same as the number of records returned, as records can span multiple lines.

DictReader objects have the following public attribute:

csvreader.fieldnames
If not passed as a parameter when creating the object, this attribute is initialized upon first access or when the first record is read from the file.

14.1.4 Writer Objects

`Writer` objects (*DictWriter* instances and objects returned by the *writer()* function) have the following public methods. A *row* must be an iterable of strings or numbers for `Writer` objects and a dictionary mapping fieldnames to strings or numbers (by passing them through *str()* first) for *DictWriter* objects. Note that complex numbers are written out surrounded by parens. This may cause some problems for other programs which read CSV files (assuming they support complex numbers at all).

csvwriter.writerow(*row*)
Write the *row* parameter to the writer's file object, formatted according to the current dialect.

Changed in version 3.5: Added support of arbitrary iterables.

csvwriter.writerows(*rows*)
Write all elements in *rows* (an iterable of *row* objects as described above) to the writer's file object, formatted according to the current dialect.

Writer objects have the following public attribute:

csvwriter.dialect
A read-only description of the dialect in use by the writer.

DictWriter objects have the following public method:

DictWriter.writeheader()
Write a row with the field names (as specified in the constructor).

New in version 3.2.

14.1.5 Examples

The simplest example of reading a CSV file:

```
import csv
with open('some.csv', newline='') as f:
    reader = csv.reader(f)
    for row in reader:
        print(row)
```

Reading a file with an alternate format:

```
import csv
with open('passwd', newline='') as f:
    reader = csv.reader(f, delimiter=':', quoting=csv.QUOTE_NONE)
    for row in reader:
        print(row)
```

The corresponding simplest possible writing example is:

```
import csv
with open('some.csv', 'w', newline='') as f:
    writer = csv.writer(f)
    writer.writerows(someiterable)
```

Since *open()* is used to open a CSV file for reading, the file will by default be decoded into unicode using the system default encoding (see *locale.getpreferredencoding()*). To decode a file using a different encoding, use the `encoding` argument of open:

```
import csv
with open('some.csv', newline='', encoding='utf-8') as f:
    reader = csv.reader(f)
    for row in reader:
        print(row)
```

The same applies to writing in something other than the system default encoding: specify the encoding argument when opening the output file.

Registering a new dialect:

```
import csv
csv.register_dialect('unixpwd', delimiter=':', quoting=csv.QUOTE_NONE)
with open('passwd', newline='') as f:
    reader = csv.reader(f, 'unixpwd')
```

A slightly more advanced use of the reader — catching and reporting errors:

```
import csv, sys
filename = 'some.csv'
with open(filename, newline='') as f:
    reader = csv.reader(f)
    try:
        for row in reader:
            print(row)
    except csv.Error as e:
        sys.exit('file {}, line {}: {}'.format(filename, reader.line_num, e))
```

And while the module doesn't directly support parsing strings, it can easily be done:

```
import csv
for row in csv.reader(['one,two,three']):
    print(row)
```

14.2 `configparser` — Configuration file parser

Source code: Lib/configparser.py

This module provides the *ConfigParser* class which implements a basic configuration language which provides a structure similar to what's found in Microsoft Windows INI files. You can use this to write Python programs which can be customized by end users easily.

Note: This library does *not* interpret or write the value-type prefixes used in the Windows Registry extended version of INI syntax.

See also:

Module *shlex* Support for creating Unix shell-like mini-languages which can be used as an alternate format for application configuration files.

Module *json* The json module implements a subset of JavaScript syntax which can also be used for this purpose.

14.2.1 Quick Start

Let's take a very basic configuration file that looks like this:

```
[DEFAULT]
ServerAliveInterval = 45
Compression = yes
CompressionLevel = 9
ForwardX11 = yes

[bitbucket.org]
User = hg

[topsecret.server.com]
Port = 50022
ForwardX11 = no
```

The structure of INI files is described *in the following section*. Essentially, the file consists of sections, each of which contains keys with values. *configparser* classes can read and write such files. Let's start by creating the above configuration file programmatically.

```
>>> import configparser
>>> config = configparser.ConfigParser()
>>> config['DEFAULT'] = {'ServerAliveInterval': '45',
...                      'Compression': 'yes',
...                      'CompressionLevel': '9'}
>>> config['bitbucket.org'] = {}
>>> config['bitbucket.org']['User'] = 'hg'
>>> config['topsecret.server.com'] = {}
>>> topsecret = config['topsecret.server.com']
>>> topsecret['Port'] = '50022'     # mutates the parser
>>> topsecret['ForwardX11'] = 'no'  # same here
>>> config['DEFAULT']['ForwardX11'] = 'yes'
>>> with open('example.ini', 'w') as configfile:
...   config.write(configfile)
...
```

As you can see, we can treat a config parser much like a dictionary. There are differences, *outlined later*, but the behavior is very close to what you would expect from a dictionary.

Now that we have created and saved a configuration file, let's read it back and explore the data it holds.

```
>>> config = configparser.ConfigParser()
>>> config.sections()
[]
```

(continues on next page)

(continued from previous page)

```
>>> config.read('example.ini')
['example.ini']
>>> config.sections()
['bitbucket.org', 'topsecret.server.com']
>>> 'bitbucket.org' in config
True
>>> 'bytebong.com' in config
False
>>> config['bitbucket.org']['User']
'hg'
>>> config['DEFAULT']['Compression']
'yes'
>>> topsecret = config['topsecret.server.com']
>>> topsecret['ForwardX11']
'no'
>>> topsecret['Port']
'50022'
>>> for key in config['bitbucket.org']:
...     print(key)
user
compressionlevel
serveraliveinterval
compression
forwardx11
>>> config['bitbucket.org']['ForwardX11']
'yes'
```

As we can see above, the API is pretty straightforward. The only bit of magic involves the `DEFAULT` section which provides default values for all other sections[1]. Note also that keys in sections are case-insensitive and stored in lowercase[1].

14.2.2 Supported Datatypes

Config parsers do not guess datatypes of values in configuration files, always storing them internally as strings. This means that if you need other datatypes, you should convert on your own:

```
>>> int(topsecret['Port'])
50022
>>> float(topsecret['CompressionLevel'])
9.0
```

Since this task is so common, config parsers provide a range of handy getter methods to handle integers, floats and booleans. The last one is the most interesting because simply passing the value to `bool()` would do no good since `bool('False')` is still `True`. This is why config parsers also provide *`getboolean()`*. This method is case-insensitive and recognizes Boolean values from `'yes'`/`'no'`, `'on'`/`'off'`, `'true'`/`'false'` and `'1'`/`'0'`[1]. For example:

```
>>> topsecret.getboolean('ForwardX11')
False
>>> config['bitbucket.org'].getboolean('ForwardX11')
True
>>> config.getboolean('bitbucket.org', 'Compression')
True
```

[1] Config parsers allow for heavy customization. If you are interested in changing the behaviour outlined by the footnote reference, consult the *Customizing Parser Behaviour* section.

Apart from *getboolean()*, config parsers also provide equivalent *getint()* and *getfloat()* methods. You can register your own converters and customize the provided ones.[1]

14.2.3 Fallback Values

As with a dictionary, you can use a section's `get()` method to provide fallback values:

```
>>> topsecret.get('Port')
'50022'
>>> topsecret.get('CompressionLevel')
'9'
>>> topsecret.get('Cipher')
>>> topsecret.get('Cipher', '3des-cbc')
'3des-cbc'
```

Please note that default values have precedence over fallback values. For instance, in our example the `'CompressionLevel'` key was specified only in the `'DEFAULT'` section. If we try to get it from the section `'topsecret.server.com'`, we will always get the default, even if we specify a fallback:

```
>>> topsecret.get('CompressionLevel', '3')
'9'
```

One more thing to be aware of is that the parser-level `get()` method provides a custom, more complex interface, maintained for backwards compatibility. When using this method, a fallback value can be provided via the `fallback` keyword-only argument:

```
>>> config.get('bitbucket.org', 'monster',
...            fallback='No such things as monsters')
'No such things as monsters'
```

The same `fallback` argument can be used with the *getint()*, *getfloat()* and *getboolean()* methods, for example:

```
>>> 'BatchMode' in topsecret
False
>>> topsecret.getboolean('BatchMode', fallback=True)
True
>>> config['DEFAULT']['BatchMode'] = 'no'
>>> topsecret.getboolean('BatchMode', fallback=True)
False
```

14.2.4 Supported INI File Structure

A configuration file consists of sections, each led by a `[section]` header, followed by key/value entries separated by a specific string (`=` or `:` by default[1]). By default, section names are case sensitive but keys are not[1]. Leading and trailing whitespace is removed from keys and values. Values can be omitted, in which case the key/value delimiter may also be left out. Values can also span multiple lines, as long as they are indented deeper than the first line of the value. Depending on the parser's mode, blank lines may be treated as parts of multiline values or ignored.

Configuration files may include comments, prefixed by specific characters (`#` and `;` by default[1]). Comments may appear on their own on an otherwise empty line, possibly indented.[1]

For example:

```
[Simple Values]
key=value
spaces in keys=allowed
spaces in values=allowed as well
spaces around the delimiter = obviously
you can also use : to delimit keys from values

[All Values Are Strings]
values like this: 1000000
or this: 3.14159265359
are they treated as numbers? : no
integers, floats and booleans are held as: strings
can use the API to get converted values directly: true

[Multiline Values]
chorus: I'm a lumberjack, and I'm okay
    I sleep all night and I work all day

[No Values]
key_without_value
empty string value here =

[You can use comments]
# like this
; or this

# By default only in an empty line.
# Inline comments can be harmful because they prevent users
# from using the delimiting characters as parts of values.
# That being said, this can be customized.

    [Sections Can Be Indented]
        can_values_be_as_well = True
        does_that_mean_anything_special = False
        purpose = formatting for readability
        multiline_values = are
            handled just fine as
            long as they are indented
            deeper than the first line
            of a value
        # Did I mention we can indent comments, too?
```

14.2.5 Interpolation of values

On top of the core functionality, *ConfigParser* supports interpolation. This means values can be preprocessed before returning them from `get()` calls.

class configparser.BasicInterpolation

The default implementation used by *ConfigParser*. It enables values to contain format strings which refer to other values in the same section, or values in the special default section[1]. Additional default values can be provided on initialization.

For example:

```
[Paths]
home_dir: /Users
```

(continues on next page)

(continued from previous page)

```
my_dir: %(home_dir)s/lumberjack
my_pictures: %(my_dir)s/Pictures
```

In the example above, *ConfigParser* with *interpolation* set to `BasicInterpolation()` would resolve `%(home_dir)s` to the value of `home_dir` (`/Users` in this case). `%(my_dir)s` in effect would resolve to `/Users/lumberjack`. All interpolations are done on demand so keys used in the chain of references do not have to be specified in any specific order in the configuration file.

With `interpolation` set to `None`, the parser would simply return `%(my_dir)s/Pictures` as the value of `my_pictures` and `%(home_dir)s/lumberjack` as the value of `my_dir`.

class configparser.ExtendedInterpolation

An alternative handler for interpolation which implements a more advanced syntax, used for instance in `zc.buildout`. Extended interpolation is using `${section:option}` to denote a value from a foreign section. Interpolation can span multiple levels. For convenience, if the `section:` part is omitted, interpolation defaults to the current section (and possibly the default values from the special section).

For example, the configuration specified above with basic interpolation, would look like this with extended interpolation:

```
[Paths]
home_dir: /Users
my_dir: ${home_dir}/lumberjack
my_pictures: ${my_dir}/Pictures
```

Values from other sections can be fetched as well:

```
[Common]
home_dir: /Users
library_dir: /Library
system_dir: /System
macports_dir: /opt/local

[Frameworks]
Python: 3.2
path: ${Common:system_dir}/Library/Frameworks/

[Arthur]
nickname: Two Sheds
last_name: Jackson
my_dir: ${Common:home_dir}/twosheds
my_pictures: ${my_dir}/Pictures
python_dir: ${Frameworks:path}/Python/Versions/${Frameworks:Python}
```

14.2.6 Mapping Protocol Access

New in version 3.2.

Mapping protocol access is a generic name for functionality that enables using custom objects as if they were dictionaries. In case of *configparser*, the mapping interface implementation is using the `parser['section']['option']` notation.

`parser['section']` in particular returns a proxy for the section's data in the parser. This means that the values are not copied but they are taken from the original parser on demand. What's even more important is that when values are changed on a section proxy, they are actually mutated in the original parser.

configparser objects behave as close to actual dictionaries as possible. The mapping interface is complete and adheres to the *MutableMapping* ABC. However, there are a few differences that should be taken into account:

- By default, all keys in sections are accessible in a case-insensitive manner[1]. E.g. `for option in parser["section"]` yields only `optionxform`'ed option key names. This means lowercased keys by default. At the same time, for a section that holds the key `'a'`, both expressions return `True`:

```
"a" in parser["section"]
"A" in parser["section"]
```

- All sections include `DEFAULTSECT` values as well which means that `.clear()` on a section may not leave the section visibly empty. This is because default values cannot be deleted from the section (because technically they are not there). If they are overridden in the section, deleting causes the default value to be visible again. Trying to delete a default value causes a `KeyError`.
- `DEFAULTSECT` cannot be removed from the parser:
  - trying to delete it raises `ValueError`,
  - `parser.clear()` leaves it intact,
  - `parser.popitem()` never returns it.
- `parser.get(section, option, **kwargs)` - the second argument is **not** a fallback value. Note however that the section-level `get()` methods are compatible both with the mapping protocol and the classic configparser API.
- `parser.items()` is compatible with the mapping protocol (returns a list of *section_name*, *section_proxy* pairs including the DEFAULTSECT). However, this method can also be invoked with arguments: `parser.items(section, raw, vars)`. The latter call returns a list of *option*, *value* pairs for a specified `section`, with all interpolations expanded (unless `raw=True` is provided).

The mapping protocol is implemented on top of the existing legacy API so that subclasses overriding the original interface still should have mappings working as expected.

14.2.7 Customizing Parser Behaviour

There are nearly as many INI format variants as there are applications using it. *configparser* goes a long way to provide support for the largest sensible set of INI styles available. The default functionality is mainly dictated by historical background and it's very likely that you will want to customize some of the features.

The most common way to change the way a specific config parser works is to use the `__init__()` options:

- *defaults*, default value: `None`

  This option accepts a dictionary of key-value pairs which will be initially put in the `DEFAULT` section. This makes for an elegant way to support concise configuration files that don't specify values which are the same as the documented default.

  Hint: if you want to specify default values for a specific section, use `read_dict()` before you read the actual file.

- *dict_type*, default value: *collections.OrderedDict*

  This option has a major impact on how the mapping protocol will behave and how the written configuration files look. With the default ordered dictionary, every section is stored in the order they were added to the parser. Same goes for options within sections.

  An alternative dictionary type can be used for example to sort sections and options on write-back. You can also use a regular dictionary for performance reasons.

Please note: there are ways to add a set of key-value pairs in a single operation. When you use a regular dictionary in those operations, the order of the keys may be random. For example:

```
>>> parser = configparser.ConfigParser()
>>> parser.read_dict({'section1': {'key1': 'value1',
...                                'key2': 'value2',
...                                'key3': 'value3'},
...                   'section2': {'keyA': 'valueA',
...                                'keyB': 'valueB',
...                                'keyC': 'valueC'},
...                   'section3': {'foo': 'x',
...                                'bar': 'y',
...                                'baz': 'z'}
... })
>>> parser.sections()
['section3', 'section2', 'section1']
>>> [option for option in parser['section3']]
['baz', 'foo', 'bar']
```

In these operations you need to use an ordered dictionary as well:

```
>>> from collections import OrderedDict
>>> parser = configparser.ConfigParser()
>>> parser.read_dict(
...   OrderedDict((
...     ('s1',
...      OrderedDict((
...        ('1', '2'),
...        ('3', '4'),
...        ('5', '6'),
...      ))
...     ),
...     ('s2',
...      OrderedDict((
...        ('a', 'b'),
...        ('c', 'd'),
...        ('e', 'f'),
...      ))
...     ),
...   ))
... )
>>> parser.sections()
['s1', 's2']
>>> [option for option in parser['s1']]
['1', '3', '5']
>>> [option for option in parser['s2'].values()]
['b', 'd', 'f']
```

- *allow_no_value*, default value: `False`

  Some configuration files are known to include settings without values, but which otherwise conform to the syntax supported by *configparser*. The *allow_no_value* parameter to the constructor can be used to indicate that such values should be accepted:

```
>>> import configparser

>>> sample_config = """
... [mysqld]
```

(continues on next page)

(continued from previous page)

```
...   user = mysql
...   pid-file = /var/run/mysqld/mysqld.pid
...   skip-external-locking
...   old_passwords = 1
...   skip-bdb
...   # we don't need ACID today
...   skip-innodb
... """
>>> config = configparser.ConfigParser(allow_no_value=True)
>>> config.read_string(sample_config)

>>> # Settings with values are treated as before:
>>> config["mysqld"]["user"]
'mysql'

>>> # Settings without values provide None:
>>> config["mysqld"]["skip-bdb"]

>>> # Settings which aren't specified still raise an error:
>>> config["mysqld"]["does-not-exist"]
Traceback (most recent call last):
  ...
KeyError: 'does-not-exist'
```

- *delimiters*, default value: `('=', ':')`

  Delimiters are substrings that delimit keys from values within a section. The first occurrence of a delimiting substring on a line is considered a delimiter. This means values (but not keys) can contain the delimiters.

  See also the *space_around_delimiters* argument to *ConfigParser.write()*.

- *comment_prefixes*, default value: `('#', ';')`

- *inline_comment_prefixes*, default value: `None`

  Comment prefixes are strings that indicate the start of a valid comment within a config file. *comment_prefixes* are used only on otherwise empty lines (optionally indented) whereas *inline_comment_prefixes* can be used after every valid value (e.g. section names, options and empty lines as well). By default inline comments are disabled and `'#'` and `';'` are used as prefixes for whole line comments.

  Changed in version 3.2: In previous versions of *configparser* behaviour matched `comment_prefixes=('#',';')` and `inline_comment_prefixes=(';',)`.

  Please note that config parsers don't support escaping of comment prefixes so using *inline_comment_prefixes* may prevent users from specifying option values with characters used as comment prefixes. When in doubt, avoid setting *inline_comment_prefixes*. In any circumstances, the only way of storing comment prefix characters at the beginning of a line in multiline values is to interpolate the prefix, for example:

```
>>> from configparser import ConfigParser, ExtendedInterpolation
>>> parser = ConfigParser(interpolation=ExtendedInterpolation())
>>> # the default BasicInterpolation could be used as well
>>> parser.read_string("""
... [DEFAULT]
... hash = #
...
... [hashes]
```

(continues on next page)

(continued from previous page)

```
... shebang =
...   ${hash}!/usr/bin/env python
...   ${hash} -*- coding: utf-8 -*-
...
... extensions =
...   enabled_extension
...   another_extension
...   #disabled_by_comment
...   yet_another_extension
...
... interpolation not necessary = if # is not at line start
... even in multiline values = line #1
...   line #2
...   line #3
... """)
>>> print(parser['hashes']['shebang'])

#!/usr/bin/env python
# -*- coding: utf-8 -*-
>>> print(parser['hashes']['extensions'])

enabled_extension
another_extension
yet_another_extension
>>> print(parser['hashes']['interpolation not necessary'])
if # is not at line start
>>> print(parser['hashes']['even in multiline values'])
line #1
line #2
line #3
```

- *strict*, default value: `True`

  When set to `True`, the parser will not allow for any section or option duplicates while reading from a single source (using `read_file()`, `read_string()` or `read_dict()`). It is recommended to use strict parsers in new applications.

  Changed in version 3.2: In previous versions of *configparser* behaviour matched `strict=False`.

- *empty_lines_in_values*, default value: `True`

  In config parsers, values can span multiple lines as long as they are indented more than the key that holds them. By default parsers also let empty lines to be parts of values. At the same time, keys can be arbitrarily indented themselves to improve readability. In consequence, when configuration files get big and complex, it is easy for the user to lose track of the file structure. Take for instance:

```
[Section]
key = multiline
  value with a gotcha

 this = is still a part of the multiline value of 'key'
```

  This can be especially problematic for the user to see if she's using a proportional font to edit the file. That is why when your application does not need values with empty lines, you should consider disallowing them. This will make empty lines split keys every time. In the example above, it would produce two keys, `key` and `this`.

- *default_section*, default value: `configparser.DEFAULTSECT` (that is: `"DEFAULT"`)

The convention of allowing a special section of default values for other sections or interpolation purposes is a powerful concept of this library, letting users create complex declarative configurations. This section is normally called `"DEFAULT"` but this can be customized to point to any other valid section name. Some typical values include: `"general"` or `"common"`. The name provided is used for recognizing default sections when reading from any source and is used when writing configuration back to a file. Its current value can be retrieved using the `parser_instance.default_section` attribute and may be modified at runtime (i.e. to convert files from one format to another).

- *interpolation*, default value: `configparser.BasicInterpolation`

  Interpolation behaviour may be customized by providing a custom handler through the *interpolation* argument. `None` can be used to turn off interpolation completely, `ExtendedInterpolation()` provides a more advanced variant inspired by `zc.buildout`. More on the subject in the *dedicated documentation section*. *`RawConfigParser`* has a default value of `None`.

- *converters*, default value: not set

  Config parsers provide option value getters that perform type conversion. By default *`getint()`*, *`getfloat()`*, and *`getboolean()`* are implemented. Should other getters be desirable, users may define them in a subclass or pass a dictionary where each key is a name of the converter and each value is a callable implementing said conversion. For instance, passing `{'decimal': decimal.Decimal}` would add `getdecimal()` on both the parser object and all section proxies. In other words, it will be possible to write both `parser_instance.getdecimal('section', 'key', fallback=0)` and `parser_instance['section'].getdecimal('key', 0)`.

  If the converter needs to access the state of the parser, it can be implemented as a method on a config parser subclass. If the name of this method starts with `get`, it will be available on all section proxies, in the dict-compatible form (see the `getdecimal()` example above).

More advanced customization may be achieved by overriding default values of these parser attributes. The defaults are defined on the classes, so they may be overridden by subclasses or by attribute assignment.

`configparser.BOOLEAN_STATES`
By default when using *`getboolean()`*, config parsers consider the following values `True`: `'1'`, `'yes'`, `'true'`, `'on'` and the following values `False`: `'0'`, `'no'`, `'false'`, `'off'`. You can override this by specifying a custom dictionary of strings and their Boolean outcomes. For example:

```
>>> custom = configparser.ConfigParser()
>>> custom['section1'] = {'funky': 'nope'}
>>> custom['section1'].getboolean('funky')
Traceback (most recent call last):
...
ValueError: Not a boolean: nope
>>> custom.BOOLEAN_STATES = {'sure': True, 'nope': False}
>>> custom['section1'].getboolean('funky')
False
```

Other typical Boolean pairs include `accept`/`reject` or `enabled`/`disabled`.

`configparser.optionxform`(*option*)
This method transforms option names on every read, get, or set operation. The default converts the name to lowercase. This also means that when a configuration file gets written, all keys will be lowercase. Override this method if that's unsuitable. For example:

```
>>> config = """
... [Section1]
... Key = Value
...
... [Section2]
```

(continues on next page)

(continued from previous page)

```
... AnotherKey = Value
... """
>>> typical = configparser.ConfigParser()
>>> typical.read_string(config)
>>> list(typical['Section1'].keys())
['key']
>>> list(typical['Section2'].keys())
['anotherkey']
>>> custom = configparser.RawConfigParser()
>>> custom.optionxform = lambda option: option
>>> custom.read_string(config)
>>> list(custom['Section1'].keys())
['Key']
>>> list(custom['Section2'].keys())
['AnotherKey']
```

`configparser.SECTCRE`
: A compiled regular expression used to parse section headers. The default matches `[section]` to the name `"section"`. Whitespace is considered part of the section name, thus `[ larch ]` will be read as a section of name `" larch "`. Override this attribute if that's unsuitable. For example:

```
>>> import re
>>> config = """
... [Section 1]
... option = value
...
... [  Section 2  ]
... another = val
... """
>>> typical = configparser.ConfigParser()
>>> typical.read_string(config)
>>> typical.sections()
['Section 1', '  Section 2  ']
>>> custom = configparser.ConfigParser()
>>> custom.SECTCRE = re.compile(r"\[ *(?P<header>[^]]+?) *\]")
>>> custom.read_string(config)
>>> custom.sections()
['Section 1', 'Section 2']
```

Note: While ConfigParser objects also use an `OPTCRE` attribute for recognizing option lines, it's not recommended to override it because that would interfere with constructor options *allow_no_value* and *delimiters*.

14.2.8 Legacy API Examples

Mainly because of backwards compatibility concerns, *configparser* provides also a legacy API with explicit `get`/`set` methods. While there are valid use cases for the methods outlined below, mapping protocol access is preferred for new projects. The legacy API is at times more advanced, low-level and downright counterintuitive.

An example of writing to a configuration file:

```
import configparser

config = configparser.RawConfigParser()

# Please note that using RawConfigParser's set functions, you can assign
# non-string values to keys internally, but will receive an error when
# attempting to write to a file or when you get it in non-raw mode. Setting
# values using the mapping protocol or ConfigParser's set() does not allow
# such assignments to take place.
config.add_section('Section1')
config.set('Section1', 'an_int', '15')
config.set('Section1', 'a_bool', 'true')
config.set('Section1', 'a_float', '3.1415')
config.set('Section1', 'baz', 'fun')
config.set('Section1', 'bar', 'Python')
config.set('Section1', 'foo', '%(bar)s is %(baz)s!')

# Writing our configuration file to 'example.cfg'
with open('example.cfg', 'w') as configfile:
    config.write(configfile)
```

An example of reading the configuration file again:

```
import configparser

config = configparser.RawConfigParser()
config.read('example.cfg')

# getfloat() raises an exception if the value is not a float
# getint() and getboolean() also do this for their respective types
a_float = config.getfloat('Section1', 'a_float')
an_int = config.getint('Section1', 'an_int')
print(a_float + an_int)

# Notice that the next output does not interpolate '%(bar)s' or '%(baz)s'.
# This is because we are using a RawConfigParser().
if config.getboolean('Section1', 'a_bool'):
    print(config.get('Section1', 'foo'))
```

To get interpolation, use *ConfigParser*:

```
import configparser

cfg = configparser.ConfigParser()
cfg.read('example.cfg')

# Set the optional *raw* argument of get() to True if you wish to disable
# interpolation in a single get operation.
print(cfg.get('Section1', 'foo', raw=False))  # -> "Python is fun!"
print(cfg.get('Section1', 'foo', raw=True))   # -> "%(bar)s is %(baz)s!"

# The optional *vars* argument is a dict with members that will take
# precedence in interpolation.
print(cfg.get('Section1', 'foo', vars={'bar': 'Documentation',
                                       'baz': 'evil'}))

# The optional *fallback* argument can be used to provide a fallback value
```

(continues on next page)

(continued from previous page)

```
print(cfg.get('Section1', 'foo'))
      # -> "Python is fun!"

print(cfg.get('Section1', 'foo', fallback='Monty is not.'))
      # -> "Python is fun!"

print(cfg.get('Section1', 'monster', fallback='No such things as monsters.'))
      # -> "No such things as monsters."

# A bare print(cfg.get('Section1', 'monster')) would raise NoOptionError
# but we can also use:

print(cfg.get('Section1', 'monster', fallback=None))
      # -> None
```

Default values are available in both types of ConfigParsers. They are used in interpolation if an option used is not defined elsewhere.

```
import configparser

# New instance with 'bar' and 'baz' defaulting to 'Life' and 'hard' each
config = configparser.ConfigParser({'bar': 'Life', 'baz': 'hard'})
config.read('example.cfg')

print(config.get('Section1', 'foo'))     # -> "Python is fun!"
config.remove_option('Section1', 'bar')
config.remove_option('Section1', 'baz')
print(config.get('Section1', 'foo'))     # -> "Life is hard!"
```

14.2.9 ConfigParser Objects

class configparser.ConfigParser(*defaults=None, dict_type=dict, allow_no_value=False, delimiters=('=', ':'), comment_prefixes=('#', ';'), inline_comment_prefixes=None, strict=True, empty_lines_in_values=True, default_section=configparser.DEFAULTSECT, interpolation=BasicInterpolation(), converters={}*)

The main configuration parser. When *defaults* is given, it is initialized into the dictionary of intrinsic defaults. When *dict_type* is given, it will be used to create the dictionary objects for the list of sections, for the options within a section, and for the default values.

When *delimiters* is given, it is used as the set of substrings that divide keys from values. When *comment_prefixes* is given, it will be used as the set of substrings that prefix comments in otherwise empty lines. Comments can be indented. When *inline_comment_prefixes* is given, it will be used as the set of substrings that prefix comments in non-empty lines.

When *strict* is `True` (the default), the parser won't allow for any section or option duplicates while reading from a single source (file, string or dictionary), raising *DuplicateSectionError* or *DuplicateOptionError*. When *empty_lines_in_values* is `False` (default: `True`), each empty line marks the end of an option. Otherwise, internal empty lines of a multiline option are kept as part of the value. When *allow_no_value* is `True` (default: `False`), options without values are accepted; the value held for these is `None` and they are serialized without the trailing delimiter.

When *default_section* is given, it specifies the name for the special section holding default values for other sections and interpolation purposes (normally named `"DEFAULT"`). This value can be retrieved and changed on runtime using the `default_section` instance attribute.

Interpolation behaviour may be customized by providing a custom handler through the *interpolation* argument. `None` can be used to turn off interpolation completely, `ExtendedInterpolation()` provides a more advanced variant inspired by `zc.buildout`. More on the subject in the *dedicated documentation section*.

All option names used in interpolation will be passed through the *optionxform()* method just like any other option name reference. For example, using the default implementation of *optionxform()* (which converts option names to lower case), the values `foo %(bar)s` and `foo %(BAR)s` are equivalent.

When *converters* is given, it should be a dictionary where each key represents the name of a type converter and each value is a callable implementing the conversion from string to the desired datatype. Every converter gets its own corresponding `get*()` method on the parser object and section proxies.

Changed in version 3.1: The default *dict_type* is *collections.OrderedDict*.

Changed in version 3.2: *allow_no_value*, *delimiters*, *comment_prefixes*, *strict*, *empty_lines_in_values*, *default_section* and *interpolation* were added.

Changed in version 3.5: The *converters* argument was added.

Changed in version 3.7: The *defaults* argument is read with *read_dict()*, providing consistent behavior across the parser: non-string keys and values are implicitly converted to strings.

Changed in version 3.7: The default *dict_type* is *dict*, since it now preserves insertion order.

defaults()
Return a dictionary containing the instance-wide defaults.

sections()
Return a list of the sections available; the *default section* is not included in the list.

add_section(*section*)
Add a section named *section* to the instance. If a section by the given name already exists, *DuplicateSectionError* is raised. If the *default section* name is passed, *ValueError* is raised. The name of the section must be a string; if not, *TypeError* is raised.

Changed in version 3.2: Non-string section names raise *TypeError*.

has_section(*section*)
Indicates whether the named *section* is present in the configuration. The *default section* is not acknowledged.

options(*section*)
Return a list of options available in the specified *section*.

has_option(*section*, *option*)
If the given *section* exists, and contains the given *option*, return *True*; otherwise return *False*. If the specified *section* is *None* or an empty string, DEFAULT is assumed.

read(*filenames*, *encoding=None*)
Attempt to read and parse a list of filenames, returning a list of filenames which were successfully parsed.

If *filenames* is a string, a *bytes* object or a *path-like object*, it is treated as a single filename. If a file named in *filenames* cannot be opened, that file will be ignored. This is designed so that you can specify a list of potential configuration file locations (for example, the current directory, the user's home directory, and some system-wide directory), and all existing configuration files in the list will be read.

If none of the named files exist, the *ConfigParser* instance will contain an empty dataset. An application which requires initial values to be loaded from a file should load the required file or files using *read_file()* before calling *read()* for any optional files:

```
import configparser, os

config = configparser.ConfigParser()
config.read_file(open('defaults.cfg'))
config.read(['site.cfg', os.path.expanduser('~/.myapp.cfg')],
            encoding='cp1250')
```

New in version 3.2: The *encoding* parameter. Previously, all files were read using the default encoding for *open()*.

New in version 3.6.1: The *filenames* parameter accepts a *path-like object*.

New in version 3.7: The *filenames* parameter accepts a *bytes* object.

read_file(*f*, *source=None*)
Read and parse configuration data from *f* which must be an iterable yielding Unicode strings (for example files opened in text mode).

Optional argument *source* specifies the name of the file being read. If not given and *f* has a `name` attribute, that is used for *source*; the default is `'<???>'`.

New in version 3.2: Replaces *readfp()*.

read_string(*string*, *source='<string>'*)
Parse configuration data from a string.

Optional argument *source* specifies a context-specific name of the string passed. If not given, `'<string>'` is used. This should commonly be a filesystem path or a URL.

New in version 3.2.

read_dict(*dictionary*, *source='<dict>'*)
Load configuration from any object that provides a dict-like `items()` method. Keys are section names, values are dictionaries with keys and values that should be present in the section. If the used dictionary type preserves order, sections and their keys will be added in order. Values are automatically converted to strings.

Optional argument *source* specifies a context-specific name of the dictionary passed. If not given, `<dict>` is used.

This method can be used to copy state between parsers.

New in version 3.2.

get(*section*, *option*, ***, *raw=False*, *vars=None*[, *fallback*])
Get an *option* value for the named *section*. If *vars* is provided, it must be a dictionary. The *option* is looked up in *vars* (if provided), *section*, and in *DEFAULTSECT* in that order. If the key is not found and *fallback* is provided, it is used as a fallback value. `None` can be provided as a *fallback* value.

All the `'%'` interpolations are expanded in the return values, unless the *raw* argument is true. Values for interpolation keys are looked up in the same manner as the option.

Changed in version 3.2: Arguments *raw*, *vars* and *fallback* are keyword only to protect users from trying to use the third argument as the *fallback* fallback (especially when using the mapping protocol).

getint(*section*, *option*, ***, *raw=False*, *vars=None*[, *fallback*])
A convenience method which coerces the *option* in the specified *section* to an integer. See *get()* for explanation of *raw*, *vars* and *fallback*.

getfloat(*section*, *option*, *, *raw=False*, *vars=None*[, *fallback*])
A convenience method which coerces the *option* in the specified *section* to a floating point number. See *get()* for explanation of *raw*, *vars* and *fallback*.

getboolean(*section*, *option*, *, *raw=False*, *vars=None*[, *fallback*])
A convenience method which coerces the *option* in the specified *section* to a Boolean value. Note that the accepted values for the option are `'1'`, `'yes'`, `'true'`, and `'on'`, which cause this method to return `True`, and `'0'`, `'no'`, `'false'`, and `'off'`, which cause it to return `False`. These string values are checked in a case-insensitive manner. Any other value will cause it to raise *ValueError*. See *get()* for explanation of *raw*, *vars* and *fallback*.

items(*raw=False*, *vars=None*)
items(*section*, *raw=False*, *vars=None*)
When *section* is not given, return a list of *section_name*, *section_proxy* pairs, including DEFAULTSECT.

Otherwise, return a list of *name*, *value* pairs for the options in the given *section*. Optional arguments have the same meaning as for the *get()* method.

set(*section*, *option*, *value*)
If the given section exists, set the given option to the specified value; otherwise raise *NoSectionError*. *option* and *value* must be strings; if not, *TypeError* is raised.

write(*fileobject*, *space_around_delimiters=True*)
Write a representation of the configuration to the specified *file object*, which must be opened in text mode (accepting strings). This representation can be parsed by a future *read()* call. If *space_around_delimiters* is true, delimiters between keys and values are surrounded by spaces.

remove_option(*section*, *option*)
Remove the specified *option* from the specified *section*. If the section does not exist, raise *NoSectionError*. If the option existed to be removed, return *True*; otherwise return *False*.

remove_section(*section*)
Remove the specified *section* from the configuration. If the section in fact existed, return `True`. Otherwise return `False`.

optionxform(*option*)
Transforms the option name *option* as found in an input file or as passed in by client code to the form that should be used in the internal structures. The default implementation returns a lower-case version of *option*; subclasses may override this or client code can set an attribute of this name on instances to affect this behavior.

You don't need to subclass the parser to use this method, you can also set it on an instance, to a function that takes a string argument and returns a string. Setting it to `str`, for example, would make option names case sensitive:

```
cfgparser = ConfigParser()
cfgparser.optionxform = str
```

Note that when reading configuration files, whitespace around the option names is stripped before *optionxform()* is called.

readfp(*fp*, *filename=None*)
Deprecated since version 3.2: Use *read_file()* instead.

Changed in version 3.2: *readfp()* now iterates on *fp* instead of calling `fp.readline()`.

For existing code calling *readfp()* with arguments which don't support iteration, the following generator may be used as a wrapper around the file-like object:

```
def readline_generator(fp):
    line = fp.readline()
    while line:
        yield line
        line = fp.readline()
```

Instead of `parser.readfp(fp)` use `parser.read_file(readline_generator(fp))`.

`configparser.MAX_INTERPOLATION_DEPTH`
The maximum depth for recursive interpolation for `get()` when the *raw* parameter is false. This is relevant only when the default *interpolation* is used.

14.2.10 RawConfigParser Objects

`class configparser.RawConfigParser`(*defaults=None, dict_type=dict, allow_no_value=False, *, delimiters=('=', ':'), comment_prefixes=('#', ';'), inline_comment_prefixes=None, strict=True, empty_lines_in_values=True, default_section=configparser.DEFAULTSECT*[, *interpolation*])

Legacy variant of the *ConfigParser*. It has interpolation disabled by default and allows for non-string section names, option names, and values via its unsafe `add_section` and `set` methods, as well as the legacy `defaults=` keyword argument handling.

Changed in version 3.7: The default *dict_type* is *dict*, since it now preserves insertion order.

Note: Consider using *ConfigParser* instead which checks types of the values to be stored internally. If you don't want interpolation, you can use `ConfigParser(interpolation=None)`.

`add_section`(*section*)
Add a section named *section* to the instance. If a section by the given name already exists, *DuplicateSectionError* is raised. If the *default section* name is passed, *ValueError* is raised.

Type of *section* is not checked which lets users create non-string named sections. This behaviour is unsupported and may cause internal errors.

`set`(*section*, *option*, *value*)
If the given section exists, set the given option to the specified value; otherwise raise *NoSectionError*. While it is possible to use *RawConfigParser* (or *ConfigParser* with *raw* parameters set to true) for *internal* storage of non-string values, full functionality (including interpolation and output to files) can only be achieved using string values.

This method lets users assign non-string values to keys internally. This behaviour is unsupported and will cause errors when attempting to write to a file or get it in non-raw mode. **Use the mapping protocol API** which does not allow such assignments to take place.

14.2.11 Exceptions

`exception configparser.Error`
Base class for all other *configparser* exceptions.

`exception configparser.NoSectionError`
Exception raised when a specified section is not found.

exception configparser.**DuplicateSectionError**
Exception raised if `add_section()` is called with the name of a section that is already present or in strict parsers when a section if found more than once in a single input file, string or dictionary.

New in version 3.2: Optional `source` and `lineno` attributes and arguments to `__init__()` were added.

exception configparser.**DuplicateOptionError**
Exception raised by strict parsers if a single option appears twice during reading from a single file, string or dictionary. This catches misspellings and case sensitivity-related errors, e.g. a dictionary may have two keys representing the same case-insensitive configuration key.

exception configparser.**NoOptionError**
Exception raised when a specified option is not found in the specified section.

exception configparser.**InterpolationError**
Base class for exceptions raised when problems occur performing string interpolation.

exception configparser.**InterpolationDepthError**
Exception raised when string interpolation cannot be completed because the number of iterations exceeds *MAX_INTERPOLATION_DEPTH*. Subclass of *InterpolationError*.

exception configparser.**InterpolationMissingOptionError**
Exception raised when an option referenced from a value does not exist. Subclass of *InterpolationError*.

exception configparser.**InterpolationSyntaxError**
Exception raised when the source text into which substitutions are made does not conform to the required syntax. Subclass of *InterpolationError*.

exception configparser.**MissingSectionHeaderError**
Exception raised when attempting to parse a file which has no section headers.

exception configparser.**ParsingError**
Exception raised when errors occur attempting to parse a file.

Changed in version 3.2: The `filename` attribute and `__init__()` argument were renamed to `source` for consistency.

14.3 netrc — netrc file processing

Source code: Lib/netrc.py

The *netrc* class parses and encapsulates the netrc file format used by the Unix **ftp** program and other FTP clients.

class netrc.**netrc**([*file*])
A *netrc* instance or subclass instance encapsulates data from a netrc file. The initialization argument, if present, specifies the file to parse. If no argument is given, the file `.netrc` in the user's home directory – as determined by *os.path.expanduser()* – will be read. Otherwise, a *FileNotFoundError* exception will be raised. Parse errors will raise *NetrcParseError* with diagnostic information including the file name, line number, and terminating token. If no argument is specified on a POSIX system, the presence of passwords in the `.netrc` file will raise a *NetrcParseError* if the file ownership or permissions are insecure (owned by a user other than the user running the process, or accessible for read or write by any other user). This implements security behavior equivalent to that of ftp and other programs that use `.netrc`.

Changed in version 3.4: Added the POSIX permission check.

Changed in version 3.7: *os.path.expanduser()* is used to find the location of the `.netrc` file when *file* is not passed as argument.

exception `netrc.NetrcParseError`
Exception raised by the *netrc* class when syntactical errors are encountered in source text. Instances of this exception provide three interesting attributes: `msg` is a textual explanation of the error, `filename` is the name of the source file, and `lineno` gives the line number on which the error was found.

14.3.1 netrc Objects

A *netrc* instance has the following methods:

`netrc.authenticators(`*host*`)`
Return a 3-tuple `(login, account, password)` of authenticators for *host*. If the netrc file did not contain an entry for the given host, return the tuple associated with the 'default' entry. If neither matching host nor default entry is available, return `None`.

`netrc.__repr__()`
Dump the class data as a string in the format of a netrc file. (This discards comments and may reorder the entries.)

Instances of *netrc* have public instance variables:

`netrc.hosts`
Dictionary mapping host names to `(login, account, password)` tuples. The 'default' entry, if any, is represented as a pseudo-host by that name.

`netrc.macros`
Dictionary mapping macro names to string lists.

Note: Passwords are limited to a subset of the ASCII character set. All ASCII punctuation is allowed in passwords, however, note that whitespace and non-printable characters are not allowed in passwords. This is a limitation of the way the .netrc file is parsed and may be removed in the future.

14.4 `xdrlib` — Encode and decode XDR data

Source code: Lib/xdrlib.py

The *xdrlib* module supports the External Data Representation Standard as described in **RFC 1014**, written by Sun Microsystems, Inc. June 1987. It supports most of the data types described in the RFC.

The *xdrlib* module defines two classes, one for packing variables into XDR representation, and another for unpacking from XDR representation. There are also two exception classes.

class `xdrlib.Packer`
Packer is the class for packing data into XDR representation. The *Packer* class is instantiated with no arguments.

class `xdrlib.Unpacker(`*data*`)`
`Unpacker` is the complementary class which unpacks XDR data values from a string buffer. The input buffer is given as *data*.

See also:

RFC 1014 - XDR: External Data Representation Standard This RFC defined the encoding of data which was XDR at the time this module was originally written. It has apparently been obsoleted by **RFC 1832**.

RFC 1832 - XDR: External Data Representation Standard Newer RFC that provides a revised definition of XDR.

14.4.1 Packer Objects

Packer instances have the following methods:

`Packer.get_buffer()`
Returns the current pack buffer as a string.

`Packer.reset()`
Resets the pack buffer to the empty string.

In general, you can pack any of the most common XDR data types by calling the appropriate `pack_type()` method. Each method takes a single argument, the value to pack. The following simple data type packing methods are supported: `pack_uint()`, `pack_int()`, `pack_enum()`, `pack_bool()`, `pack_uhyper()`, and `pack_hyper()`.

`Packer.pack_float(`*value*`)`
Packs the single-precision floating point number *value*.

`Packer.pack_double(`*value*`)`
Packs the double-precision floating point number *value*.

The following methods support packing strings, bytes, and opaque data:

`Packer.pack_fstring(`*n*, *s*`)`
Packs a fixed length string, *s*. *n* is the length of the string but it is *not* packed into the data buffer. The string is padded with null bytes if necessary to guaranteed 4 byte alignment.

`Packer.pack_fopaque(`*n*, *data*`)`
Packs a fixed length opaque data stream, similarly to *pack_fstring()*.

`Packer.pack_string(`*s*`)`
Packs a variable length string, *s*. The length of the string is first packed as an unsigned integer, then the string data is packed with *pack_fstring()*.

`Packer.pack_opaque(`*data*`)`
Packs a variable length opaque data string, similarly to *pack_string()*.

`Packer.pack_bytes(`*bytes*`)`
Packs a variable length byte stream, similarly to *pack_string()*.

The following methods support packing arrays and lists:

`Packer.pack_list(`*list*, *pack_item*`)`
Packs a *list* of homogeneous items. This method is useful for lists with an indeterminate size; i.e. the size is not available until the entire list has been walked. For each item in the list, an unsigned integer `1` is packed first, followed by the data value from the list. *pack_item* is the function that is called to pack the individual item. At the end of the list, an unsigned integer `0` is packed.

For example, to pack a list of integers, the code might appear like this:

```
import xdrlib
p = xdrlib.Packer()
p.pack_list([1, 2, 3], p.pack_int)
```

Packer.**pack_farray**(*n*, *array*, *pack_item*)
Packs a fixed length list (*array*) of homogeneous items. *n* is the length of the list; it is *not* packed into the buffer, but a *ValueError* exception is raised if `len(array)` is not equal to *n*. As above, *pack_item* is the function used to pack each element.

Packer.**pack_array**(*list*, *pack_item*)
Packs a variable length *list* of homogeneous items. First, the length of the list is packed as an unsigned integer, then each element is packed as in *pack_farray()* above.

14.4.2 Unpacker Objects

The *Unpacker* class offers the following methods:

Unpacker.**reset**(*data*)
Resets the string buffer with the given *data*.

Unpacker.**get_position**()
Returns the current unpack position in the data buffer.

Unpacker.**set_position**(*position*)
Sets the data buffer unpack position to *position*. You should be careful about using *get_position()* and *set_position()*.

Unpacker.**get_buffer**()
Returns the current unpack data buffer as a string.

Unpacker.**done**()
Indicates unpack completion. Raises an *Error* exception if all of the data has not been unpacked.

In addition, every data type that can be packed with a *Packer*, can be unpacked with an *Unpacker*. Unpacking methods are of the form `unpack_type()`, and take no arguments. They return the unpacked object.

Unpacker.**unpack_float**()
Unpacks a single-precision floating point number.

Unpacker.**unpack_double**()
Unpacks a double-precision floating point number, similarly to *unpack_float()*.

In addition, the following methods unpack strings, bytes, and opaque data:

Unpacker.**unpack_fstring**(*n*)
Unpacks and returns a fixed length string. *n* is the number of characters expected. Padding with null bytes to guaranteed 4 byte alignment is assumed.

Unpacker.**unpack_fopaque**(*n*)
Unpacks and returns a fixed length opaque data stream, similarly to *unpack_fstring()*.

Unpacker.**unpack_string**()
Unpacks and returns a variable length string. The length of the string is first unpacked as an unsigned integer, then the string data is unpacked with *unpack_fstring()*.

Unpacker.**unpack_opaque**()
Unpacks and returns a variable length opaque data string, similarly to *unpack_string()*.

Unpacker.**unpack_bytes**()
Unpacks and returns a variable length byte stream, similarly to *unpack_string()*.

The following methods support unpacking arrays and lists:

Unpacker.**unpack_list**(*unpack_item*)
Unpacks and returns a list of homogeneous items. The list is unpacked one element at a time by first unpacking an unsigned integer flag. If the flag is `1`, then the item is unpacked and appended to the

list. A flag of 0 indicates the end of the list. *unpack_item* is the function that is called to unpack the items.

Unpacker.unpack_farray(*n*, *unpack_item*)
Unpacks and returns (as a list) a fixed length array of homogeneous items. *n* is number of list elements to expect in the buffer. As above, *unpack_item* is the function used to unpack each element.

Unpacker.unpack_array(*unpack_item*)
Unpacks and returns a variable length *list* of homogeneous items. First, the length of the list is unpacked as an unsigned integer, then each element is unpacked as in *unpack_farray()* above.

14.4.3 Exceptions

Exceptions in this module are coded as class instances:

exception xdrlib.Error
The base exception class. *Error* has a single public attribute **msg** containing the description of the error.

exception xdrlib.ConversionError
Class derived from *Error*. Contains no additional instance variables.

Here is an example of how you would catch one of these exceptions:

```
import xdrlib
p = xdrlib.Packer()
try:
    p.pack_double(8.01)
except xdrlib.ConversionError as instance:
    print('packing the double failed:', instance.msg)
```

14.5 plistlib — Generate and parse Mac OS X .plist files

Source code: Lib/plistlib.py

This module provides an interface for reading and writing the "property list" files used mainly by Mac OS X and supports both binary and XML plist files.

The property list (.plist) file format is a simple serialization supporting basic object types, like dictionaries, lists, numbers and strings. Usually the top level object is a dictionary.

To write out and to parse a plist file, use the *dump()* and *load()* functions.

To work with plist data in bytes objects, use *dumps()* and *loads()*.

Values can be strings, integers, floats, booleans, tuples, lists, dictionaries (but only with string keys), *Data*, *bytes*, bytesarray or *datetime.datetime* objects.

Changed in version 3.4: New API, old API deprecated. Support for binary format plists added.

See also:

PList manual page Apple's documentation of the file format.

This module defines the following functions:

plistlib.load(*fp*, *, *fmt=None*, *use_builtin_types=True*, *dict_type=dict*)
Read a plist file. *fp* should be a readable and binary file object. Return the unpacked root object (which usually is a dictionary).

The *fmt* is the format of the file and the following values are valid:

- *None*: Autodetect the file format
- *FMT_XML*: XML file format
- *FMT_BINARY*: Binary plist format

If *use_builtin_types* is true (the default) binary data will be returned as instances of *bytes*, otherwise it is returned as instances of *Data*.

The *dict_type* is the type used for dictionaries that are read from the plist file.

XML data for the *FMT_XML* format is parsed using the Expat parser from *xml.parsers.expat* – see its documentation for possible exceptions on ill-formed XML. Unknown elements will simply be ignored by the plist parser.

The parser for the binary format raises `InvalidFileException` when the file cannot be parsed.

New in version 3.4.

plistlib.loads(*data*, *, *fmt=None*, *use_builtin_types=True*, *dict_type=dict*)
Load a plist from a bytes object. See *load()* for an explanation of the keyword arguments.

New in version 3.4.

plistlib.dump(*value*, *fp*, *, *fmt=FMT_XML*, *sort_keys=True*, *skipkeys=False*)
Write *value* to a plist file. *Fp* should be a writable, binary file object.

The *fmt* argument specifies the format of the plist file and can be one of the following values:

- *FMT_XML*: XML formatted plist file
- *FMT_BINARY*: Binary formatted plist file

When *sort_keys* is true (the default) the keys for dictionaries will be written to the plist in sorted order, otherwise they will be written in the iteration order of the dictionary.

When *skipkeys* is false (the default) the function raises *TypeError* when a key of a dictionary is not a string, otherwise such keys are skipped.

A *TypeError* will be raised if the object is of an unsupported type or a container that contains objects of unsupported types.

An *OverflowError* will be raised for integer values that cannot be represented in (binary) plist files.

New in version 3.4.

plistlib.dumps(*value*, *, *fmt=FMT_XML*, *sort_keys=True*, *skipkeys=False*)
Return *value* as a plist-formatted bytes object. See the documentation for *dump()* for an explanation of the keyword arguments of this function.

New in version 3.4.

The following functions are deprecated:

plistlib.readPlist(*pathOrFile*)
Read a plist file. *pathOrFile* may be either a file name or a (readable and binary) file object. Returns the unpacked root object (which usually is a dictionary).

This function calls *load()* to do the actual work, see the documentation of *that function* for an explanation of the keyword arguments.

Deprecated since version 3.4: Use *load()* instead.

Changed in version 3.7: Dict values in the result are now normal dicts. You no longer can use attribute access to access items of these dictionaries.

plistlib.writePlist(*rootObject*, *pathOrFile*)
Write *rootObject* to an XML plist file. *pathOrFile* may be either a file name or a (writable and binary) file object

Deprecated since version 3.4: Use *dump()* instead.

plistlib.readPlistFromBytes(*data*)
Read a plist data from a bytes object. Return the root object.

See *load()* for a description of the keyword arguments.

Deprecated since version 3.4: Use *loads()* instead.

Changed in version 3.7: Dict values in the result are now normal dicts. You no longer can use attribute access to access items of these dictionaries.

plistlib.writePlistToBytes(*rootObject*)
Return *rootObject* as an XML plist-formatted bytes object.

Deprecated since version 3.4: Use *dumps()* instead.

The following classes are available:

class plistlib.Data(*data*)
Return a "data" wrapper object around the bytes object *data*. This is used in functions converting from/to plists to represent the `<data>` type available in plists.

It has one attribute, `data`, that can be used to retrieve the Python bytes object stored in it.

Deprecated since version 3.4: Use a *bytes* object instead.

The following constants are available:

plistlib.FMT_XML
The XML format for plist files.

New in version 3.4.

plistlib.FMT_BINARY
The binary format for plist files

New in version 3.4.

14.5.1 Examples

Generating a plist:

```
pl = dict(
    aString = "Doodah",
    aList = ["A", "B", 12, 32.1, [1, 2, 3]],
    aFloat = 0.1,
    anInt = 728,
    aDict = dict(
        anotherString = "<hello & hi there!>",
        aThirdString = "M\xe4ssig, Ma\xdf",
        aTrueValue = True,
        aFalseValue = False,
    ),
    someData = b"<binary gunk>",
    someMoreData = b"<lots of binary gunk>" * 10,
    aDate = datetime.datetime.fromtimestamp(time.mktime(time.gmtime())),
```

(continues on next page)

(continued from previous page)

```
)
with open(fileName, 'wb') as fp:
    dump(pl, fp)
```

Parsing a plist:

```
with open(fileName, 'rb') as fp:
    pl = load(fp)
print(pl["aKey"])
```

CHAPTER

FIFTEEN

CRYPTOGRAPHIC SERVICES

The modules described in this chapter implement various algorithms of a cryptographic nature. They are available at the discretion of the installation. On Unix systems, the *crypt* module may also be available. Here's an overview:

15.1 hashlib — Secure hashes and message digests

Source code: Lib/hashlib.py

This module implements a common interface to many different secure hash and message digest algorithms. Included are the FIPS secure hash algorithms SHA1, SHA224, SHA256, SHA384, and SHA512 (defined in FIPS 180-2) as well as RSA's MD5 algorithm (defined in Internet **RFC 1321**). The terms "secure hash" and "message digest" are interchangeable. Older algorithms were called message digests. The modern term is secure hash.

Note: If you want the adler32 or crc32 hash functions, they are available in the *zlib* module.

Warning: Some algorithms have known hash collision weaknesses, refer to the "See also" section at the end.

15.1.1 Hash algorithms

There is one constructor method named for each type of *hash*. All return a hash object with the same simple interface. For example: use `sha256()` to create a SHA-256 hash object. You can now feed this object with *bytes-like objects* (normally *bytes*) using the `update()` method. At any point you can ask it for the *digest* of the concatenation of the data fed to it so far using the `digest()` or `hexdigest()` methods.

Note: For better multithreading performance, the Python *GIL* is released for data larger than 2047 bytes at object creation or on update.

Note: Feeding string objects into `update()` is not supported, as hashes work on bytes, not on characters.

Constructors for hash algorithms that are always present in this module are `sha1()`, `sha224()`, `sha256()`, `sha384()`, `sha512()`, *blake2b()*, and *blake2s()*. `md5()` is normally available as well, though it may be

missing if you are using a rare "FIPS compliant" build of Python. Additional algorithms may also be available depending upon the OpenSSL library that Python uses on your platform. On most platforms the `sha3_224()`, `sha3_256()`, `sha3_384()`, `sha3_512()`, `shake_128()`, `shake_256()` are also available.

New in version 3.6: SHA3 (Keccak) and SHAKE constructors `sha3_224()`, `sha3_256()`, `sha3_384()`, `sha3_512()`, `shake_128()`, `shake_256()`.

New in version 3.6: *blake2b()* and *blake2s()* were added.

For example, to obtain the digest of the byte string `b'Nobody inspects the spammish repetition'`:

```
>>> import hashlib
>>> m = hashlib.sha256()
>>> m.update(b"Nobody inspects")
>>> m.update(b" the spammish repetition")
>>> m.digest()
b'\x03\x1e\xdd}Ae\x15\x93\xc5\xfe\\\x00o\xa5u+7\xfd\xdf\xf7\xbcN\x84:\xa6\xaf\x0c\x95\x0fK\x94\x06'
>>> m.digest_size
32
>>> m.block_size
64
```

More condensed:

```
>>> hashlib.sha224(b"Nobody inspects the spammish repetition").hexdigest()
'a4337bc45a8fc544c03f52dc550cd6e1e87021bc896588bd79e901e2'
```

hashlib.new(*name*[, *data*])
: Is a generic constructor that takes the string name of the desired algorithm as its first parameter. It also exists to allow access to the above listed hashes as well as any other algorithms that your OpenSSL library may offer. The named constructors are much faster than *new()* and should be preferred.

Using *new()* with an algorithm provided by OpenSSL:

```
>>> h = hashlib.new('ripemd160')
>>> h.update(b"Nobody inspects the spammish repetition")
>>> h.hexdigest()
'cc4a5ce1b3df48aec5d22d1f16b894a0b894eccc'
```

Hashlib provides the following constant attributes:

hashlib.algorithms_guaranteed
: A set containing the names of the hash algorithms guaranteed to be supported by this module on all platforms. Note that 'md5' is in this list despite some upstream vendors offering an odd "FIPS compliant" Python build that excludes it.

  New in version 3.2.

hashlib.algorithms_available
: A set containing the names of the hash algorithms that are available in the running Python interpreter. These names will be recognized when passed to *new()*. *algorithms_guaranteed* will always be a subset. The same algorithm may appear multiple times in this set under different names (thanks to OpenSSL).

  New in version 3.2.

The following values are provided as constant attributes of the hash objects returned by the constructors:

hash.digest_size
: The size of the resulting hash in bytes.

hash.block_size
: The internal block size of the hash algorithm in bytes.

A hash object has the following attributes:

`hash.name`
: The canonical name of this hash, always lowercase and always suitable as a parameter to *new()* to create another hash of this type.

  Changed in version 3.4: The name attribute has been present in CPython since its inception, but until Python 3.4 was not formally specified, so may not exist on some platforms.

A hash object has the following methods:

`hash.update(`*arg*`)`
: Update the hash object with the object *arg*, which must be interpretable as a buffer of bytes. Repeated calls are equivalent to a single call with the concatenation of all the arguments: `m.update(a); m.update(b)` is equivalent to `m.update(a+b)`.

  Changed in version 3.1: The Python GIL is released to allow other threads to run while hash updates on data larger than 2047 bytes is taking place when using hash algorithms supplied by OpenSSL.

`hash.digest()`
: Return the digest of the data passed to the *update()* method so far. This is a bytes object of size *digest_size* which may contain bytes in the whole range from 0 to 255.

`hash.hexdigest()`
: Like *digest()* except the digest is returned as a string object of double length, containing only hexadecimal digits. This may be used to exchange the value safely in email or other non-binary environments.

`hash.copy()`
: Return a copy ("clone") of the hash object. This can be used to efficiently compute the digests of data sharing a common initial substring.

15.1.2 SHAKE variable length digests

The `shake_128()` and `shake_256()` algorithms provide variable length digests with length_in_bits//2 up to 128 or 256 bits of security. As such, their digest methods require a length. Maximum length is not limited by the SHAKE algorithm.

`shake.digest(`*length*`)`
: Return the digest of the data passed to the `update()` method so far. This is a bytes object of size `length` which may contain bytes in the whole range from 0 to 255.

`shake.hexdigest(`*length*`)`
: Like *digest()* except the digest is returned as a string object of double length, containing only hexadecimal digits. This may be used to exchange the value safely in email or other non-binary environments.

15.1.3 Key derivation

Key derivation and key stretching algorithms are designed for secure password hashing. Naive algorithms such as `sha1(password)` are not resistant against brute-force attacks. A good password hashing function must be tunable, slow, and include a salt.

`hashlib.pbkdf2_hmac(`*hash_name*, *password*, *salt*, *iterations*, *dklen=None*`)`
: The function provides PKCS#5 password-based key derivation function 2. It uses HMAC as pseudo-random function.

  The string *hash_name* is the desired name of the hash digest algorithm for HMAC, e.g. 'sha1' or 'sha256'. *password* and *salt* are interpreted as buffers of bytes. Applications and libraries should limit *password* to a sensible length (e.g. 1024). *salt* should be about 16 or more bytes from a proper source, e.g. *os.urandom()*.

The number of *iterations* should be chosen based on the hash algorithm and computing power. As of 2013, at least 100,000 iterations of SHA-256 are suggested.

dklen is the length of the derived key. If *dklen* is `None` then the digest size of the hash algorithm *hash_name* is used, e.g. 64 for SHA-512.

```
>>> import hashlib, binascii
>>> dk = hashlib.pbkdf2_hmac('sha256', b'password', b'salt', 100000)
>>> binascii.hexlify(dk)
b'0394a2ede332c9a13eb82e9b24631604c31df978b4e2f0fbd2c549944f9d79a5'
```

New in version 3.4.

Note: A fast implementation of *pbkdf2_hmac* is available with OpenSSL. The Python implementation uses an inline version of *hmac*. It is about three times slower and doesn't release the GIL.

`hashlib.scrypt`(*password*, ***, *salt*, *n*, *r*, *p*, *maxmem=0*, *dklen=64*)

The function provides scrypt password-based key derivation function as defined in **RFC 7914**.

password and *salt* must be bytes-like objects. Applications and libraries should limit *password* to a sensible length (e.g. 1024). *salt* should be about 16 or more bytes from a proper source, e.g. *os.urandom()*.

n is the CPU/Memory cost factor, *r* the block size, *p* parallelization factor and *maxmem* limits memory (OpenSSL 1.1.0 defaults to 32 MiB). *dklen* is the length of the derived key.

Availability: OpenSSL 1.1+

New in version 3.6.

15.1.4 BLAKE2

BLAKE2 is a cryptographic hash function defined in **RFC 7693** that comes in two flavors:

- **BLAKE2b**, optimized for 64-bit platforms and produces digests of any size between 1 and 64 bytes,
- **BLAKE2s**, optimized for 8- to 32-bit platforms and produces digests of any size between 1 and 32 bytes.

BLAKE2 supports **keyed mode** (a faster and simpler replacement for HMAC), **salted hashing**, **personalization**, and **tree hashing**.

Hash objects from this module follow the API of standard library's *hashlib* objects.

Creating hash objects

New hash objects are created by calling constructor functions:

`hashlib.blake2b`(*data=b''*, *digest_size=64*, *key=b''*, *salt=b''*, *person=b''*, *fanout=1*, *depth=1*, *leaf_size=0*, *node_offset=0*, *node_depth=0*, *inner_size=0*, *last_node=False*)

`hashlib.blake2s`(*data=b''*, *digest_size=32*, *key=b''*, *salt=b''*, *person=b''*, *fanout=1*, *depth=1*, *leaf_size=0*, *node_offset=0*, *node_depth=0*, *inner_size=0*, *last_node=False*)

These functions return the corresponding hash objects for calculating BLAKE2b or BLAKE2s. They optionally take these general parameters:

- *data*: initial chunk of data to hash, which must be interpretable as buffer of bytes.
- *digest_size*: size of output digest in bytes.
- *key*: key for keyed hashing (up to 64 bytes for BLAKE2b, up to 32 bytes for BLAKE2s).

- *salt*: salt for randomized hashing (up to 16 bytes for BLAKE2b, up to 8 bytes for BLAKE2s).
- *person*: personalization string (up to 16 bytes for BLAKE2b, up to 8 bytes for BLAKE2s).

The following table shows limits for general parameters (in bytes):

Hash	digest_size	len(key)	len(salt)	len(person)
BLAKE2b	64	64	16	16
BLAKE2s	32	32	8	8

Note: BLAKE2 specification defines constant lengths for salt and personalization parameters, however, for convenience, this implementation accepts byte strings of any size up to the specified length. If the length of the parameter is less than specified, it is padded with zeros, thus, for example, `b'salt'` and `b'salt\x00'` is the same value. (This is not the case for *key*.)

These sizes are available as module *constants* described below.

Constructor functions also accept the following tree hashing parameters:

- *fanout*: fanout (0 to 255, 0 if unlimited, 1 in sequential mode).
- *depth*: maximal depth of tree (1 to 255, 255 if unlimited, 1 in sequential mode).
- *leaf_size*: maximal byte length of leaf (0 to 2**32-1, 0 if unlimited or in sequential mode).
- *node_offset*: node offset (0 to 2**64-1 for BLAKE2b, 0 to 2**48-1 for BLAKE2s, 0 for the first, leftmost, leaf, or in sequential mode).
- *node_depth*: node depth (0 to 255, 0 for leaves, or in sequential mode).
- *inner_size*: inner digest size (0 to 64 for BLAKE2b, 0 to 32 for BLAKE2s, 0 in sequential mode).
- *last_node*: boolean indicating whether the processed node is the last one (*False* for sequential mode).

See section 2.10 in BLAKE2 specification for comprehensive review of tree hashing.

Constants

`blake2b.SALT_SIZE`

`blake2s.SALT_SIZE`

Salt length (maximum length accepted by constructors).

`blake2b.PERSON_SIZE`

`blake2s.PERSON_SIZE`

Personalization string length (maximum length accepted by constructors).

`blake2b.MAX_KEY_SIZE`

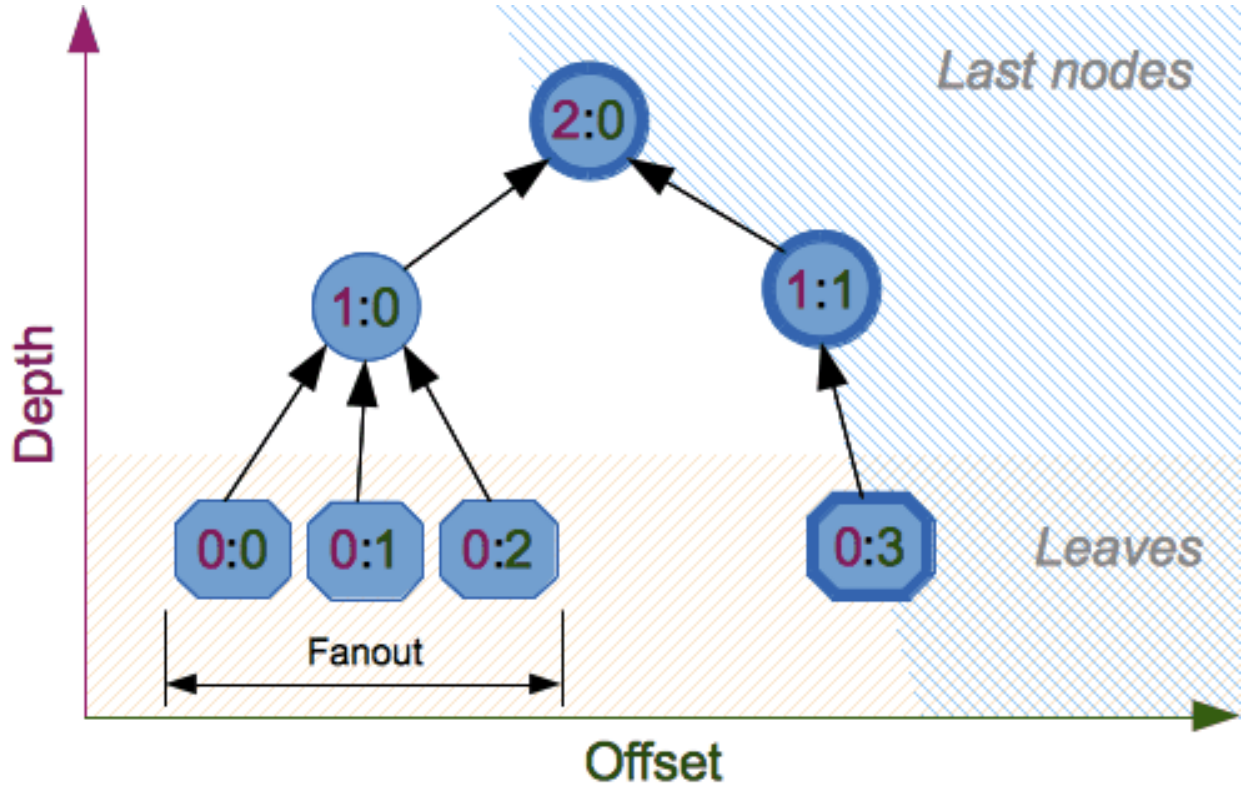
`blake2s.MAX_KEY_SIZE`

Maximum key size.

`blake2b.MAX_DIGEST_SIZE`

`blake2s.MAX_DIGEST_SIZE`

Maximum digest size that the hash function can output.



Examples

Simple hashing

To calculate hash of some data, you should first construct a hash object by calling the appropriate constructor function (*blake2b()* or *blake2s()*), then update it with the data by calling `update()` on the object, and, finally, get the digest out of the object by calling `digest()` (or `hexdigest()` for hex-encoded string).

```
>>> from hashlib import blake2b
>>> h = blake2b()
>>> h.update(b'Hello world')
>>> h.hexdigest()

↪'6ff843ba685842aa82031d3f53c48b66326df7639a63d128974c5c14f31a0f33343a8c65551134ed1ae0f2b0dd2bb495dc81039e3eeb0aa1
↪'
```

As a shortcut, you can pass the first chunk of data to update directly to the constructor as the first argument (or as *data* keyword argument):

```
>>> from hashlib import blake2b
>>> blake2b(b'Hello world').hexdigest()

↪'6ff843ba685842aa82031d3f53c48b66326df7639a63d128974c5c14f31a0f33343a8c65551134ed1ae0f2b0dd2bb495dc81039e3eeb0aa1
↪'
```

You can call *hash.update()* as many times as you need to iteratively update the hash:

```
>>> from hashlib import blake2b
>>> items = [b'Hello', b' ', b'world']
>>> h = blake2b()
>>> for item in items:
...     h.update(item)
>>> h.hexdigest()

↪'6ff843ba685842aa82031d3f53c48b66326df7639a63d128974c5c14f31a0f33343a8c65551134ed1ae0f2b0dd2bb495dc81039e3eeb0aa1
↪'
```

Using different digest sizes

BLAKE2 has configurable size of digests up to 64 bytes for BLAKE2b and up to 32 bytes for BLAKE2s. For example, to replace SHA-1 with BLAKE2b without changing the size of output, we can tell BLAKE2b to produce 20-byte digests:

```
>>> from hashlib import blake2b
>>> h = blake2b(digest_size=20)
>>> h.update(b'Replacing SHA1 with the more secure function')
>>> h.hexdigest()
'd24f26cf8de66472d58d4e1b1774b4c9158b1f4c'
>>> h.digest_size
20
>>> len(h.digest())
20
```

Hash objects with different digest sizes have completely different outputs (shorter hashes are *not* prefixes of longer hashes); BLAKE2b and BLAKE2s produce different outputs even if the output length is the same:

```
>>> from hashlib import blake2b, blake2s
>>> blake2b(digest_size=10).hexdigest()
'6fa1d8fcfd719046d762'
>>> blake2b(digest_size=11).hexdigest()
'eb6ec15daf9546254f0809'
>>> blake2s(digest_size=10).hexdigest()
'1bf21a98c78a1c376ae9'
>>> blake2s(digest_size=11).hexdigest()
'567004bf96e4a25773ebf4'
```

Keyed hashing

Keyed hashing can be used for authentication as a faster and simpler replacement for Hash-based message authentication code (HMAC). BLAKE2 can be securely used in prefix-MAC mode thanks to the indifferentiability property inherited from BLAKE.

This example shows how to get a (hex-encoded) 128-bit authentication code for message `b'message data'` with key `b'pseudorandom key'`:

```
>>> from hashlib import blake2b
>>> h = blake2b(key=b'pseudorandom key', digest_size=16)
>>> h.update(b'message data')
>>> h.hexdigest()
'3d363ff7401e02026f4a4687d4863ced'
```

As a practical example, a web application can symmetrically sign cookies sent to users and later verify them to make sure they weren't tampered with:

```
>>> from hashlib import blake2b
>>> from hmac import compare_digest
>>>
>>> SECRET_KEY = b'pseudorandomly generated server secret key'
>>> AUTH_SIZE = 16
>>>
>>> def sign(cookie):
...     h = blake2b(digest_size=AUTH_SIZE, key=SECRET_KEY)
...     h.update(cookie)
...     return h.hexdigest().encode('utf-8')
>>>
>>> def verify(cookie, sig):
...     good_sig = sign(cookie)
...     return compare_digest(good_sig, sig)
>>>
>>> cookie = b'user-alice'
>>> sig = sign(cookie)
>>> print("{0},{1}".format(cookie.decode('utf-8'), sig))
user-alice,b'43b3c982cf697e0c5ab22172d1ca7421'
>>> verify(cookie, sig)
True
>>> verify(b'user-bob', sig)
False
>>> verify(cookie, b'0102030405060708090a0b0c0d0e0f00')
False
```

Even though there's a native keyed hashing mode, BLAKE2 can, of course, be used in HMAC construction with *hmac* module:

```
>>> import hmac, hashlib
>>> m = hmac.new(b'secret key', digestmod=hashlib.blake2s)
>>> m.update(b'message')
>>> m.hexdigest()
'e3c8102868d28b5ff85fc35dda07329970d1a01e273c37481326fe0c861c8142'
```

Randomized hashing

By setting *salt* parameter users can introduce randomization to the hash function. Randomized hashing is useful for protecting against collision attacks on the hash function used in digital signatures.

> Randomized hashing is designed for situations where one party, the message preparer, generates all or part of a message to be signed by a second party, the message signer. If the message preparer is able to find cryptographic hash function collisions (i.e., two messages producing the same hash value), then they might prepare meaningful versions of the message that would produce the same hash value and digital signature, but with different results (e.g., transferring $1,000,000 to an account, rather than $10). Cryptographic hash functions have been designed with collision resistance as a major goal, but the current concentration on attacking cryptographic hash functions may result in a given cryptographic hash function providing less collision resistance than expected. Randomized hashing offers the signer additional protection by reducing the likelihood that a preparer can generate two or more messages that ultimately yield the same hash value during the digital signature generation process — even if it is practical to find collisions for the hash function. However, the use of randomized hashing may reduce the amount of security provided by a digital signature when all portions of the message are prepared by the signer.

(NIST SP-800-106 "Randomized Hashing for Digital Signatures")

In BLAKE2 the salt is processed as a one-time input to the hash function during initialization, rather than as an input to each compression function.

Warning: *Salted hashing* (or just hashing) with BLAKE2 or any other general-purpose cryptographic hash function, such as SHA-256, is not suitable for hashing passwords. See BLAKE2 FAQ for more information.

```
>>> import os
>>> from hashlib import blake2b
>>> msg = b'some message'
>>> # Calculate the first hash with a random salt.
>>> salt1 = os.urandom(blake2b.SALT_SIZE)
>>> h1 = blake2b(salt=salt1)
>>> h1.update(msg)
>>> # Calculate the second hash with a different random salt.
>>> salt2 = os.urandom(blake2b.SALT_SIZE)
>>> h2 = blake2b(salt=salt2)
>>> h2.update(msg)
>>> # The digests are different.
>>> h1.digest() != h2.digest()
True
```

Personalization

Sometimes it is useful to force hash function to produce different digests for the same input for different purposes. Quoting the authors of the Skein hash function:

> We recommend that all application designers seriously consider doing this; we have seen many protocols where a hash that is computed in one part of the protocol can be used in an entirely different part because two hash computations were done on similar or related data, and the attacker can force the application to make the hash inputs the same. Personalizing each hash function used in the protocol summarily stops this type of attack.
>
> (The Skein Hash Function Family, p. 21)

BLAKE2 can be personalized by passing bytes to the *person* argument:

```
>>> from hashlib import blake2b
>>> FILES_HASH_PERSON = b'MyApp Files Hash'
>>> BLOCK_HASH_PERSON = b'MyApp Block Hash'
>>> h = blake2b(digest_size=32, person=FILES_HASH_PERSON)
>>> h.update(b'the same content')
>>> h.hexdigest()
'20d9cd024d4fb086aae819a1432dd2466de12947831b75c5a30cf2676095d3b4'
>>> h = blake2b(digest_size=32, person=BLOCK_HASH_PERSON)
>>> h.update(b'the same content')
>>> h.hexdigest()
'cf68fb5761b9c44e7878bfb2c4c9aea52264a80b75005e65619778de59f383a3'
```

Personalization together with the keyed mode can also be used to derive different keys from a single one.

```
>>> from hashlib import blake2s
>>> from base64 import b64decode, b64encode
```

(continues on next page)

(continued from previous page)

```
>>> orig_key = b64decode(b'Rm5EPJai72qcK3RGBpW3vPNfZy5OZothY+kHY6h21KM=')
>>> enc_key = blake2s(key=orig_key, person=b'kEncrypt').digest()
>>> mac_key = blake2s(key=orig_key, person=b'kMAC').digest()
>>> print(b64encode(enc_key).decode('utf-8'))
rbPb15S/Z9t+agffno5wuhB77VbRi6F9Iv2qIxU7WHw=
>>> print(b64encode(mac_key).decode('utf-8'))
G9GtHFE1YluXY1zWPlYk1e/nWfu0WSEb0KRcjhDeP/o=
```

Tree mode

Here's an example of hashing a minimal tree with two leaf nodes:

```
  10
 /  \
00  01
```

This example uses 64-byte internal digests, and returns the 32-byte final digest:

```
>>> from hashlib import blake2b
>>>
>>> FANOUT = 2
>>> DEPTH = 2
>>> LEAF_SIZE = 4096
>>> INNER_SIZE = 64
>>>
>>> buf = bytearray(6000)
>>>
>>> # Left leaf
... h00 = blake2b(buf[0:LEAF_SIZE], fanout=FANOUT, depth=DEPTH,
...               leaf_size=LEAF_SIZE, inner_size=INNER_SIZE,
...               node_offset=0, node_depth=0, last_node=False)
>>> # Right leaf
... h01 = blake2b(buf[LEAF_SIZE:], fanout=FANOUT, depth=DEPTH,
...               leaf_size=LEAF_SIZE, inner_size=INNER_SIZE,
...               node_offset=1, node_depth=0, last_node=True)
>>> # Root node
... h10 = blake2b(digest_size=32, fanout=FANOUT, depth=DEPTH,
...               leaf_size=LEAF_SIZE, inner_size=INNER_SIZE,
...               node_offset=0, node_depth=1, last_node=True)
>>> h10.update(h00.digest())
>>> h10.update(h01.digest())
>>> h10.hexdigest()
'3ad2a9b37c6070e374c7a8c508fe20ca86b6ed54e286e93a0318e95e881db5aa'
```

Credits

BLAKE2 was designed by *Jean-Philippe Aumasson*, *Samuel Neves*, *Zooko Wilcox-O'Hearn*, and *Christian Winnerlein* based on SHA-3 finalist BLAKE created by *Jean-Philippe Aumasson*, *Luca Henzen*, *Willi Meier*, and *Raphael C.-W. Phan*.

It uses core algorithm from ChaCha cipher designed by *Daniel J. Bernstein*.

The stdlib implementation is based on pyblake2 module. It was written by *Dmitry Chestnykh* based on C implementation written by *Samuel Neves*. The documentation was copied from pyblake2 and written by *Dmitry Chestnykh*.

The C code was partly rewritten for Python by *Christian Heimes*.

The following public domain dedication applies for both C hash function implementation, extension code, and this documentation:

15.2 hmac — Keyed-Hashing for Message Authentication

Source code: Lib/hmac.py

This module implements the HMAC algorithm as described by **RFC 2104**.

`hmac.new`(*key*, *msg=None*, *digestmod=None*)

Return a new hmac object. *key* is a bytes or bytearray object giving the secret key. If *msg* is present, the method call `update(msg)` is made. *digestmod* is the digest name, digest constructor or module for the HMAC object to use. It supports any name suitable to *hashlib.new()* and defaults to the `hashlib.md5` constructor.

Changed in version 3.4: Parameter *key* can be a bytes or bytearray object. Parameter *msg* can be of any type supported by *hashlib*. Parameter *digestmod* can be the name of a hash algorithm.

Deprecated since version 3.4, will be removed in version 3.8: MD5 as implicit default digest for *digestmod* is deprecated.

`hmac.digest`(*key*, *msg*, *digest*)

Return digest of *msg* for given secret *key* and *digest*. The function is equivalent to `HMAC(key, msg, digest).digest()`, but uses an optimized C or inline implementation, which is faster for messages that fit into memory. The parameters *key*, *msg*, and *digest* have the same meaning as in *new()*.

CPython implementation detail, the optimized C implementation is only used when *digest* is a string and name of a digest algorithm, which is supported by OpenSSL.

New in version 3.7.

An HMAC object has the following methods:

HMAC.update(*msg*)
Update the hmac object with *msg*. Repeated calls are equivalent to a single call with the concatenation of all the arguments: `m.update(a); m.update(b)` is equivalent to `m.update(a + b)`.

Changed in version 3.4: Parameter *msg* can be of any type supported by *hashlib*.

HMAC.digest()
Return the digest of the bytes passed to the *update()* method so far. This bytes object will be the same length as the *digest_size* of the digest given to the constructor. It may contain non-ASCII bytes, including NUL bytes.

> **Warning:** When comparing the output of *digest()* to an externally-supplied digest during a verification routine, it is recommended to use the *compare_digest()* function instead of the `==` operator to reduce the vulnerability to timing attacks.

HMAC.hexdigest()
Like *digest()* except the digest is returned as a string twice the length containing only hexadecimal digits. This may be used to exchange the value safely in email or other non-binary environments.

> **Warning:** When comparing the output of *hexdigest()* to an externally-supplied digest during a verification routine, it is recommended to use the *compare_digest()* function instead of the `==` operator to reduce the vulnerability to timing attacks.

HMAC.copy()
Return a copy ("clone") of the hmac object. This can be used to efficiently compute the digests of strings that share a common initial substring.

A hash object has the following attributes:

HMAC.digest_size
The size of the resulting HMAC digest in bytes.

HMAC.block_size
The internal block size of the hash algorithm in bytes.

New in version 3.4.

HMAC.name
The canonical name of this HMAC, always lowercase, e.g. `hmac-md5`.

New in version 3.4.

This module also provides the following helper function:

hmac.compare_digest(*a*, *b*)
Return `a == b`. This function uses an approach designed to prevent timing analysis by avoiding content-based short circuiting behaviour, making it appropriate for cryptography. *a* and *b* must both be of the same type: either *str* (ASCII only, as e.g. returned by *HMAC.hexdigest()*), or a *bytes-like object*.

> **Note:** If *a* and *b* are of different lengths, or if an error occurs, a timing attack could theoretically reveal information about the types and lengths of *a* and *b*—but not their values.

New in version 3.3.

See also:

Module *hashlib* The Python module providing secure hash functions.

15.3 secrets — Generate secure random numbers for managing secrets

New in version 3.6.

Source code: Lib/secrets.py

The *secrets* module is used for generating cryptographically strong random numbers suitable for managing data such as passwords, account authentication, security tokens, and related secrets.

In particularly, *secrets* should be used in preference to the default pseudo-random number generator in the *random* module, which is designed for modelling and simulation, not security or cryptography.

See also:

PEP 506

15.3.1 Random numbers

The *secrets* module provides access to the most secure source of randomness that your operating system provides.

class secrets.SystemRandom
A class for generating random numbers using the highest-quality sources provided by the operating system. See *random.SystemRandom* for additional details.

secrets.choice(*sequence*)
Return a randomly-chosen element from a non-empty sequence.

secrets.randbelow(*n*)
Return a random int in the range [0, *n*).

secrets.randbits(*k*)
Return an int with *k* random bits.

15.3.2 Generating tokens

The *secrets* module provides functions for generating secure tokens, suitable for applications such as password resets, hard-to-guess URLs, and similar.

secrets.token_bytes([*nbytes=None*])
Return a random byte string containing *nbytes* number of bytes. If *nbytes* is `None` or not supplied, a reasonable default is used.

```
>>> token_bytes(16)
b'\xebr\x17D*t\xae\xd4\xe3S\xb6\xe2\xebP1\x8b'
```

secrets.token_hex([*nbytes=None*])
Return a random text string, in hexadecimal. The string has *nbytes* random bytes, each byte converted to two hex digits. If *nbytes* is `None` or not supplied, a reasonable default is used.

```
>>> token_hex(16)
'f9bf78b9a18ce6d46a0cd2b0b86df9da'
```

secrets.token_urlsafe([*nbytes=None*])
Return a random URL-safe text string, containing *nbytes* random bytes. The text is Base64 encoded, so on average each byte results in approximately 1.3 characters. If *nbytes* is `None` or not supplied, a reasonable default is used.

```
>>> token_urlsafe(16)
'Drmhze6EPcv0fN_81Bj-nA'
```

How many bytes should tokens use?

To be secure against brute-force attacks, tokens need to have sufficient randomness. Unfortunately, what is considered sufficient will necessarily increase as computers get more powerful and able to make more guesses in a shorter period. As of 2015, it is believed that 32 bytes (256 bits) of randomness is sufficient for the typical use-case expected for the *secrets* module.

For those who want to manage their own token length, you can explicitly specify how much randomness is used for tokens by giving an *int* argument to the various `token_*` functions. That argument is taken as the number of bytes of randomness to use.

Otherwise, if no argument is provided, or if the argument is `None`, the `token_*` functions will use a reasonable default instead.

Note: That default is subject to change at any time, including during maintenance releases.

15.3.3 Other functions

secrets.compare_digest(*a*, *b*)
Return `True` if strings *a* and *b* are equal, otherwise `False`, in such a way as to reduce the risk of timing attacks. See *hmac.compare_digest()* for additional details.

15.3.4 Recipes and best practices

This section shows recipes and best practices for using *secrets* to manage a basic level of security.

Generate an eight-character alphanumeric password:

```
import string
alphabet = string.ascii_letters + string.digits
password = ''.join(choice(alphabet) for i in range(8))
```

Note: Applications should not store passwords in a recoverable format, whether plain text or encrypted. They should be salted and hashed using a cryptographically-strong one-way (irreversible) hash function.

Generate a ten-character alphanumeric password with at least one lowercase character, at least one uppercase character, and at least three digits:

```
import string
alphabet = string.ascii_letters + string.digits
while True:
    password = ''.join(choice(alphabet) for i in range(10))
    if (any(c.islower() for c in password)
```

(continues on next page)

(continued from previous page)

```
            and any(c.isupper() for c in password)
            and sum(c.isdigit() for c in password) >= 3):
        break
```

Generate an XKCD-style passphrase:

```
# On standard Linux systems, use a convenient dictionary file.
# Other platforms may need to provide their own word-list.
with open('/usr/share/dict/words') as f:
    words = [word.strip() for word in f]
    password = ' '.join(choice(words) for i in range(4))
```

Generate a hard-to-guess temporary URL containing a security token suitable for password recovery applications:

```
url = 'https://mydomain.com/reset=' + token_urlsafe()
```

CHAPTER

SIXTEEN

GENERIC OPERATING SYSTEM SERVICES

The modules described in this chapter provide interfaces to operating system features that are available on (almost) all operating systems, such as files and a clock. The interfaces are generally modeled after the Unix or C interfaces, but they are available on most other systems as well. Here's an overview:

16.1 os — Miscellaneous operating system interfaces

Source code: Lib/os.py

This module provides a portable way of using operating system dependent functionality. If you just want to read or write a file see *open()*, if you want to manipulate paths, see the *os.path* module, and if you want to read all the lines in all the files on the command line see the *fileinput* module. For creating temporary files and directories see the *tempfile* module, and for high-level file and directory handling see the *shutil* module.

Notes on the availability of these functions:

- The design of all built-in operating system dependent modules of Python is such that as long as the same functionality is available, it uses the same interface; for example, the function `os.stat(path)` returns stat information about *path* in the same format (which happens to have originated with the POSIX interface).
- Extensions peculiar to a particular operating system are also available through the *os* module, but using them is of course a threat to portability.
- All functions accepting path or file names accept both bytes and string objects, and result in an object of the same type, if a path or file name is returned.
- An "Availability: Unix" note means that this function is commonly found on Unix systems. It does not make any claims about its existence on a specific operating system.
- If not separately noted, all functions that claim "Availability: Unix" are supported on Mac OS X, which builds on a Unix core.

Note: All functions in this module raise *OSError* in the case of invalid or inaccessible file names and paths, or other arguments that have the correct type, but are not accepted by the operating system.

---

exception os.error
An alias for the built-in *OSError* exception.

os.name
The name of the operating system dependent module imported. The following names have currently been registered: `'posix'`, `'nt'`, `'java'`.

See also:

sys.platform has a finer granularity. *os.uname()* gives system-dependent version information.

The *platform* module provides detailed checks for the system's identity.

16.1.1 File Names, Command Line Arguments, and Environment Variables

In Python, file names, command line arguments, and environment variables are represented using the string type. On some systems, decoding these strings to and from bytes is necessary before passing them to the operating system. Python uses the file system encoding to perform this conversion (see *sys.getfilesystemencoding()*).

Changed in version 3.1: On some systems, conversion using the file system encoding may fail. In this case, Python uses the *surrogateescape encoding error handler*, which means that undecodable bytes are replaced by a Unicode character U+DCxx on decoding, and these are again translated to the original byte on encoding.

The file system encoding must guarantee to successfully decode all bytes below 128. If the file system encoding fails to provide this guarantee, API functions may raise UnicodeErrors.

16.1.2 Process Parameters

These functions and data items provide information and operate on the current process and user.

`os.ctermid()`
Return the filename corresponding to the controlling terminal of the process.

Availability: Unix.

`os.environ`
A *mapping* object representing the string environment. For example, `environ['HOME']` is the pathname of your home directory (on some platforms), and is equivalent to `getenv("HOME")` in C.

This mapping is captured the first time the *os* module is imported, typically during Python startup as part of processing `site.py`. Changes to the environment made after this time are not reflected in `os.environ`, except for changes made by modifying `os.environ` directly.

If the platform supports the *putenv()* function, this mapping may be used to modify the environment as well as query the environment. *putenv()* will be called automatically when the mapping is modified.

On Unix, keys and values use *sys.getfilesystemencoding()* and `'surrogateescape'` error handler. Use *environb* if you would like to use a different encoding.

Note: Calling *putenv()* directly does not change `os.environ`, so it's better to modify `os.environ`.

Note: On some platforms, including FreeBSD and Mac OS X, setting `environ` may cause memory leaks. Refer to the system documentation for `putenv()`.

If *putenv()* is not provided, a modified copy of this mapping may be passed to the appropriate process-creation functions to cause child processes to use a modified environment.

If the platform supports the *unsetenv()* function, you can delete items in this mapping to unset environment variables. *unsetenv()* will be called automatically when an item is deleted from `os.environ`, and when one of the `pop()` or `clear()` methods is called.

os.environb
: Bytes version of *environ*: a *mapping* object representing the environment as byte strings. *environ* and *environb* are synchronized (modify *environb* updates *environ*, and vice versa).

  environb is only available if *supports_bytes_environ* is True.

  New in version 3.2.

os.chdir(*path*)
os.fchdir(*fd*)
os.getcwd()
: These functions are described in *Files and Directories*.

os.fsencode(*filename*)
: Encode *path-like* *filename* to the filesystem encoding with 'surrogateescape' error handler, or 'strict' on Windows; return *bytes* unchanged.

  fsdecode() is the reverse function.

  New in version 3.2.

  Changed in version 3.6: Support added to accept objects implementing the *os.PathLike* interface.

os.fsdecode(*filename*)
: Decode the *path-like* *filename* from the filesystem encoding with 'surrogateescape' error handler, or 'strict' on Windows; return *str* unchanged.

  fsencode() is the reverse function.

  New in version 3.2.

  Changed in version 3.6: Support added to accept objects implementing the *os.PathLike* interface.

os.fspath(*path*)
: Return the file system representation of the path.

  If *str* or *bytes* is passed in, it is returned unchanged. Otherwise *__fspath__()* is called and its value is returned as long as it is a *str* or *bytes* object. In all other cases, *TypeError* is raised.

  New in version 3.6.

class os.PathLike
: An *abstract base class* for objects representing a file system path, e.g. *pathlib.PurePath*.

  New in version 3.6.

  abstractmethod __fspath__()
  : Return the file system path representation of the object.

    The method should only return a *str* or *bytes* object, with the preference being for *str*.

os.getenv(*key*, *default=None*)
: Return the value of the environment variable *key* if it exists, or *default* if it doesn't. *key*, *default* and the result are str.

  On Unix, keys and values are decoded with *sys.getfilesystemencoding()* and 'surrogateescape' error handler. Use *os.getenvb()* if you would like to use a different encoding.

  Availability: most flavors of Unix, Windows.

os.getenvb(*key*, *default=None*)
: Return the value of the environment variable *key* if it exists, or *default* if it doesn't. *key*, *default* and the result are bytes.

  getenvb() is only available if *supports_bytes_environ* is True.

  Availability: most flavors of Unix.

New in version 3.2.

os.get_exec_path(*env=None*)
Returns the list of directories that will be searched for a named executable, similar to a shell, when launching a process. *env*, when specified, should be an environment variable dictionary to lookup the PATH in. By default, when *env* is None, *environ* is used.

New in version 3.2.

os.getegid()
Return the effective group id of the current process. This corresponds to the "set id" bit on the file being executed in the current process.

Availability: Unix.

os.geteuid()
Return the current process's effective user id.

Availability: Unix.

os.getgid()
Return the real group id of the current process.

Availability: Unix.

os.getgrouplist(*user*, *group*)
Return list of group ids that *user* belongs to. If *group* is not in the list, it is included; typically, *group* is specified as the group ID field from the password record for *user*.

Availability: Unix.

New in version 3.3.

os.getgroups()
Return list of supplemental group ids associated with the current process.

Availability: Unix.

Note: On Mac OS X, *getgroups()* behavior differs somewhat from other Unix platforms. If the Python interpreter was built with a deployment target of 10.5 or earlier, *getgroups()* returns the list of effective group ids associated with the current user process; this list is limited to a system-defined number of entries, typically 16, and may be modified by calls to *setgroups()* if suitably privileged. If built with a deployment target greater than 10.5, *getgroups()* returns the current group access list for the user associated with the effective user id of the process; the group access list may change over the lifetime of the process, it is not affected by calls to *setgroups()*, and its length is not limited to 16. The deployment target value, MACOSX_DEPLOYMENT_TARGET, can be obtained with *sysconfig.get_config_var()*.

---

os.getlogin()
Return the name of the user logged in on the controlling terminal of the process. For most purposes, it is more useful to use *getpass.getuser()* since the latter checks the environment variables LOGNAME or USERNAME to find out who the user is, and falls back to pwd.getpwuid(os.getuid())[0] to get the login name of the current real user id.

Availability: Unix, Windows.

os.getpgid(*pid*)
Return the process group id of the process with process id *pid*. If *pid* is 0, the process group id of the current process is returned.

Availability: Unix.

os.**getpgrp**()
Return the id of the current process group.

Availability: Unix.

os.**getpid**()
Return the current process id.

os.**getppid**()
Return the parent's process id. When the parent process has exited, on Unix the id returned is the one of the init process (1), on Windows it is still the same id, which may be already reused by another process.

Availability: Unix, Windows.

Changed in version 3.2: Added support for Windows.

os.**getpriority**(*which*, *who*)
Get program scheduling priority. The value *which* is one of *PRIO_PROCESS*, *PRIO_PGRP*, or *PRIO_USER*, and *who* is interpreted relative to *which* (a process identifier for *PRIO_PROCESS*, process group identifier for *PRIO_PGRP*, and a user ID for *PRIO_USER*). A zero value for *who* denotes (respectively) the calling process, the process group of the calling process, or the real user ID of the calling process.

Availability: Unix.

New in version 3.3.

os.**PRIO_PROCESS**
os.**PRIO_PGRP**
os.**PRIO_USER**
Parameters for the *getpriority()* and *setpriority()* functions.

Availability: Unix.

New in version 3.3.

os.**getresuid**()
Return a tuple (ruid, euid, suid) denoting the current process's real, effective, and saved user ids.

Availability: Unix.

New in version 3.2.

os.**getresgid**()
Return a tuple (rgid, egid, sgid) denoting the current process's real, effective, and saved group ids.

Availability: Unix.

New in version 3.2.

os.**getuid**()
Return the current process's real user id.

Availability: Unix.

os.**initgroups**(*username*, *gid*)
Call the system initgroups() to initialize the group access list with all of the groups of which the specified username is a member, plus the specified group id.

Availability: Unix.

New in version 3.2.

os.**putenv**(*key*, *value*)
Set the environment variable named *key* to the string *value*. Such changes to the environment affect subprocesses started with *os.system()*, *popen()* or *fork()* and *execv()*.

Availability: most flavors of Unix, Windows.

Note: On some platforms, including FreeBSD and Mac OS X, setting `environ` may cause memory leaks. Refer to the system documentation for putenv.

When *putenv()* is supported, assignments to items in `os.environ` are automatically translated into corresponding calls to *putenv()*; however, calls to *putenv()* don't update `os.environ`, so it is actually preferable to assign to items of `os.environ`.

`os.setegid(`*egid*`)`
Set the current process's effective group id.

Availability: Unix.

`os.seteuid(`*euid*`)`
Set the current process's effective user id.

Availability: Unix.

`os.setgid(`*gid*`)`
Set the current process' group id.

Availability: Unix.

`os.setgroups(`*groups*`)`
Set the list of supplemental group ids associated with the current process to *groups*. *groups* must be a sequence, and each element must be an integer identifying a group. This operation is typically available only to the superuser.

Availability: Unix.

Note: On Mac OS X, the length of *groups* may not exceed the system-defined maximum number of effective group ids, typically 16. See the documentation for *getgroups()* for cases where it may not return the same group list set by calling setgroups().

`os.setpgrp()`
Call the system call `setpgrp()` or `setpgrp(0, 0)` depending on which version is implemented (if any). See the Unix manual for the semantics.

Availability: Unix.

`os.setpgid(`*pid*, *pgrp*`)`
Call the system call `setpgid()` to set the process group id of the process with id *pid* to the process group with id *pgrp*. See the Unix manual for the semantics.

Availability: Unix.

`os.setpriority(`*which*, *who*, *priority*`)`
Set program scheduling priority. The value *which* is one of *PRIO_PROCESS*, *PRIO_PGRP*, or *PRIO_USER*, and *who* is interpreted relative to *which* (a process identifier for *PRIO_PROCESS*, process group identifier for *PRIO_PGRP*, and a user ID for *PRIO_USER*). A zero value for *who* denotes (respectively) the calling process, the process group of the calling process, or the real user ID of the calling process. *priority* is a value in the range -20 to 19. The default priority is 0; lower priorities cause more favorable scheduling.

Availability: Unix

New in version 3.3.

`os.setregid(`*rgid*, *egid*`)`
Set the current process's real and effective group ids.

Availability: Unix.

os.**setresgid**(*rgid*, *egid*, *sgid*)
Set the current process's real, effective, and saved group ids.

Availability: Unix.

New in version 3.2.

os.**setresuid**(*ruid*, *euid*, *suid*)
Set the current process's real, effective, and saved user ids.

Availability: Unix.

New in version 3.2.

os.**setreuid**(*ruid*, *euid*)
Set the current process's real and effective user ids.

Availability: Unix.

os.**getsid**(*pid*)
Call the system call `getsid()`. See the Unix manual for the semantics.

Availability: Unix.

os.**setsid**()
Call the system call `setsid()`. See the Unix manual for the semantics.

Availability: Unix.

os.**setuid**(*uid*)
Set the current process's user id.

Availability: Unix.

os.**strerror**(*code*)
Return the error message corresponding to the error code in *code*. On platforms where `strerror()` returns `NULL` when given an unknown error number, *ValueError* is raised.

os.**supports_bytes_environ**
`True` if the native OS type of the environment is bytes (eg. `False` on Windows).

New in version 3.2.

os.**umask**(*mask*)
Set the current numeric umask and return the previous umask.

os.**uname**()
Returns information identifying the current operating system. The return value is an object with five attributes:

- `sysname` - operating system name
- `nodename` - name of machine on network (implementation-defined)
- `release` - operating system release
- `version` - operating system version
- `machine` - hardware identifier

For backwards compatibility, this object is also iterable, behaving like a five-tuple containing `sysname`, `nodename`, `release`, `version`, and `machine` in that order.

Some systems truncate `nodename` to 8 characters or to the leading component; a better way to get the hostname is *socket.gethostname()* or even `socket.gethostbyaddr(socket.gethostname())`.

Availability: recent flavors of Unix.

Changed in version 3.3: Return type changed from a tuple to a tuple-like object with named attributes.

os.unsetenv(*key*)
Unset (delete) the environment variable named *key*. Such changes to the environment affect subprocesses started with *os.system()*, *popen()* or *fork()* and *execv()*.

When *unsetenv()* is supported, deletion of items in os.environ is automatically translated into a corresponding call to *unsetenv()*; however, calls to *unsetenv()* don't update os.environ, so it is actually preferable to delete items of os.environ.

Availability: most flavors of Unix, Windows.

16.1.3 File Object Creation

This function creates new *file objects*. (See also *open()* for opening file descriptors.)

os.fdopen(*fd*, **args*, ***kwargs*)
Return an open file object connected to the file descriptor *fd*. This is an alias of the *open()* built-in function and accepts the same arguments. The only difference is that the first argument of *fdopen()* must always be an integer.

16.1.4 File Descriptor Operations

These functions operate on I/O streams referenced using file descriptors.

File descriptors are small integers corresponding to a file that has been opened by the current process. For example, standard input is usually file descriptor 0, standard output is 1, and standard error is 2. Further files opened by a process will then be assigned 3, 4, 5, and so forth. The name "file descriptor" is slightly deceptive; on Unix platforms, sockets and pipes are also referenced by file descriptors.

The *fileno()* method can be used to obtain the file descriptor associated with a *file object* when required. Note that using the file descriptor directly will bypass the file object methods, ignoring aspects such as internal buffering of data.

os.close(*fd*)
Close file descriptor *fd*.

Note: This function is intended for low-level I/O and must be applied to a file descriptor as returned by *os.open()* or *pipe()*. To close a "file object" returned by the built-in function *open()* or by *popen()* or *fdopen()*, use its *close()* method.

---

os.closerange(*fd_low*, *fd_high*)
Close all file descriptors from *fd_low* (inclusive) to *fd_high* (exclusive), ignoring errors. Equivalent to (but much faster than):

```
for fd in range(fd_low, fd_high):
    try:
        os.close(fd)
    except OSError:
        pass
```

os.device_encoding(*fd*)
Return a string describing the encoding of the device associated with *fd* if it is connected to a terminal; else return *None*.

os.dup(*fd*)
Return a duplicate of file descriptor *fd*. The new file descriptor is *non-inheritable*.

On Windows, when duplicating a standard stream (0: stdin, 1: stdout, 2: stderr), the new file descriptor is *inheritable*.

Changed in version 3.4: The new file descriptor is now non-inheritable.

`os.dup2`(*fd*, *fd2*, *inheritable=True*)
Duplicate file descriptor *fd* to *fd2*, closing the latter first if necessary. Return *fd2*. The new file descriptor is *inheritable* by default or non-inheritable if *inheritable* is `False`.

Changed in version 3.4: Add the optional *inheritable* parameter.

Changed in version 3.7: Return *fd2* on success. Previously, `None` was always returned.

`os.fchmod`(*fd*, *mode*)
Change the mode of the file given by *fd* to the numeric *mode*. See the docs for *chmod()* for possible values of *mode*. As of Python 3.3, this is equivalent to `os.chmod(fd, mode)`.

Availability: Unix.

`os.fchown`(*fd*, *uid*, *gid*)
Change the owner and group id of the file given by *fd* to the numeric *uid* and *gid*. To leave one of the ids unchanged, set it to -1. See *chown()*. As of Python 3.3, this is equivalent to `os.chown(fd, uid, gid)`.

Availability: Unix.

`os.fdatasync`(*fd*)
Force write of file with filedescriptor *fd* to disk. Does not force update of metadata.

Availability: Unix.

Note: This function is not available on MacOS.

`os.fpathconf`(*fd*, *name*)
Return system configuration information relevant to an open file. *name* specifies the configuration value to retrieve; it may be a string which is the name of a defined system value; these names are specified in a number of standards (POSIX.1, Unix 95, Unix 98, and others). Some platforms define additional names as well. The names known to the host operating system are given in the `pathconf_names` dictionary. For configuration variables not included in that mapping, passing an integer for *name* is also accepted.

If *name* is a string and is not known, *ValueError* is raised. If a specific value for *name* is not supported by the host system, even if it is included in `pathconf_names`, an *OSError* is raised with *errno.EINVAL* for the error number.

As of Python 3.3, this is equivalent to `os.pathconf(fd, name)`.

Availability: Unix.

`os.fstat`(*fd*)
Get the status of the file descriptor *fd*. Return a *stat_result* object.

As of Python 3.3, this is equivalent to `os.stat(fd)`.

See also:

The *stat()* function.

`os.fstatvfs`(*fd*)
Return information about the filesystem containing the file associated with file descriptor *fd*, like *statvfs()*. As of Python 3.3, this is equivalent to `os.statvfs(fd)`.

Availability: Unix.

os.fsync(*fd*)
Force write of file with filedescriptor *fd* to disk. On Unix, this calls the native `fsync()` function; on Windows, the MS `_commit()` function.

If you're starting with a buffered Python *file object* *f*, first do `f.flush()`, and then do `os.fsync(f.fileno())`, to ensure that all internal buffers associated with *f* are written to disk.

Availability: Unix, Windows.

os.ftruncate(*fd*, *length*)
Truncate the file corresponding to file descriptor *fd*, so that it is at most *length* bytes in size. As of Python 3.3, this is equivalent to `os.truncate(fd, length)`.

Availability: Unix, Windows.

Changed in version 3.5: Added support for Windows

os.get_blocking(*fd*)
Get the blocking mode of the file descriptor: `False` if the *O_NONBLOCK* flag is set, `True` if the flag is cleared.

See also *set_blocking()* and *socket.socket.setblocking()*.

Availability: Unix.

New in version 3.5.

os.isatty(*fd*)
Return `True` if the file descriptor *fd* is open and connected to a tty(-like) device, else `False`.

os.lockf(*fd*, *cmd*, *len*)
Apply, test or remove a POSIX lock on an open file descriptor. *fd* is an open file descriptor. *cmd* specifies the command to use - one of *F_LOCK*, *F_TLOCK*, *F_ULOCK* or *F_TEST*. *len* specifies the section of the file to lock.

Availability: Unix.

New in version 3.3.

os.F_LOCK
os.F_TLOCK
os.F_ULOCK
os.F_TEST
Flags that specify what action *lockf()* will take.

Availability: Unix.

New in version 3.3.

os.lseek(*fd*, *pos*, *how*)
Set the current position of file descriptor *fd* to position *pos*, modified by *how*: *SEEK_SET* or `0` to set the position relative to the beginning of the file; *SEEK_CUR* or `1` to set it relative to the current position; *SEEK_END* or `2` to set it relative to the end of the file. Return the new cursor position in bytes, starting from the beginning.

os.SEEK_SET
os.SEEK_CUR
os.SEEK_END
Parameters to the *lseek()* function. Their values are 0, 1, and 2, respectively.

New in version 3.3: Some operating systems could support additional values, like `os.SEEK_HOLE` or `os.SEEK_DATA`.

os.open(*path*, *flags*, *mode=0o777*, ***, *dir_fd=None*)
Open the file *path* and set various flags according to *flags* and possibly its mode according to *mode*.

When computing *mode*, the current umask value is first masked out. Return the file descriptor for the newly opened file. The new file descriptor is *non-inheritable*.

For a description of the flag and mode values, see the C run-time documentation; flag constants (like *O_RDONLY* and *O_WRONLY*) are defined in the *os* module. In particular, on Windows adding *O_BINARY* is needed to open files in binary mode.

This function can support *paths relative to directory descriptors* with the *dir_fd* parameter.

Changed in version 3.4: The new file descriptor is now non-inheritable.

Note: This function is intended for low-level I/O. For normal usage, use the built-in function *open()*, which returns a *file object* with `read()` and `write()` methods (and many more). To wrap a file descriptor in a file object, use *fdopen()*.

New in version 3.3: The *dir_fd* argument.

Changed in version 3.5: If the system call is interrupted and the signal handler does not raise an exception, the function now retries the system call instead of raising an *InterruptedError* exception (see **PEP 475** for the rationale).

Changed in version 3.6: Accepts a *path-like object*.

The following constants are options for the *flags* parameter to the *open()* function. They can be combined using the bitwise OR operator `|`. Some of them are not available on all platforms. For descriptions of their availability and use, consult the *open(2)* manual page on Unix or the MSDN on Windows.

`os.O_RDONLY`
`os.O_WRONLY`
`os.O_RDWR`
`os.O_APPEND`
`os.O_CREAT`
`os.O_EXCL`
`os.O_TRUNC`
The above constants are available on Unix and Windows.

`os.O_DSYNC`
`os.O_RSYNC`
`os.O_SYNC`
`os.O_NDELAY`
`os.O_NONBLOCK`
`os.O_NOCTTY`
`os.O_CLOEXEC`
The above constants are only available on Unix.

Changed in version 3.3: Add *O_CLOEXEC* constant.

`os.O_BINARY`
`os.O_NOINHERIT`
`os.O_SHORT_LIVED`
`os.O_TEMPORARY`
`os.O_RANDOM`
`os.O_SEQUENTIAL`
`os.O_TEXT`
The above constants are only available on Windows.

`os.O_ASYNC`
`os.O_DIRECT`
`os.O_DIRECTORY`

os.O_NOFOLLOW
os.O_NOATIME
os.O_PATH
os.O_TMPFILE
os.O_SHLOCK
os.O_EXLOCK

The above constants are extensions and not present if they are not defined by the C library.

Changed in version 3.4: Add *O_PATH* on systems that support it. Add *O_TMPFILE*, only available on Linux Kernel 3.11 or newer.

os.openpty()

Open a new pseudo-terminal pair. Return a pair of file descriptors `(master, slave)` for the pty and the tty, respectively. The new file descriptors are *non-inheritable*. For a (slightly) more portable approach, use the *pty* module.

Availability: some flavors of Unix.

Changed in version 3.4: The new file descriptors are now non-inheritable.

os.pipe()

Create a pipe. Return a pair of file descriptors `(r, w)` usable for reading and writing, respectively. The new file descriptor is *non-inheritable*.

Availability: Unix, Windows.

Changed in version 3.4: The new file descriptors are now non-inheritable.

os.pipe2(*flags*)

Create a pipe with *flags* set atomically. *flags* can be constructed by ORing together one or more of these values: *O_NONBLOCK*, *O_CLOEXEC*. Return a pair of file descriptors `(r, w)` usable for reading and writing, respectively.

Availability: some flavors of Unix.

New in version 3.3.

os.posix_fallocate(*fd*, *offset*, *len*)

Ensures that enough disk space is allocated for the file specified by *fd* starting from *offset* and continuing for *len* bytes.

Availability: Unix.

New in version 3.3.

os.posix_fadvise(*fd*, *offset*, *len*, *advice*)

Announces an intention to access data in a specific pattern thus allowing the kernel to make optimizations. The advice applies to the region of the file specified by *fd* starting at *offset* and continuing for *len* bytes. *advice* is one of *POSIX_FADV_NORMAL*, *POSIX_FADV_SEQUENTIAL*, *POSIX_FADV_RANDOM*, *POSIX_FADV_NOREUSE*, *POSIX_FADV_WILLNEED* or *POSIX_FADV_DONTNEED*.

Availability: Unix.

New in version 3.3.

os.POSIX_FADV_NORMAL
os.POSIX_FADV_SEQUENTIAL
os.POSIX_FADV_RANDOM
os.POSIX_FADV_NOREUSE
os.POSIX_FADV_WILLNEED
os.POSIX_FADV_DONTNEED

Flags that can be used in *advice* in *posix_fadvise()* that specify the access pattern that is likely to be used.

Availability: Unix.

New in version 3.3.

os.pread(*fd*, *n*, *offset*)
Read at most *n* bytes from file descriptor *fd* at a position of *offset*, leaving the file offset unchanged.

Return a bytestring containing the bytes read. If the end of the file referred to by *fd* has been reached, an empty bytes object is returned.

Availability: Unix.

New in version 3.3.

os.preadv(*fd*, *buffers*, *offset*, *flags=0*)
Read from a file descriptor *fd* at a position of *offset* into mutable *bytes-like objects* *buffers*, leaving the file offset unchanged. Transfer data into each buffer until it is full and then move on to the next buffer in the sequence to hold the rest of the data.

The flags argument contains a bitwise OR of zero or more of the following flags:

- *RWF_HIPRI*
- *RWF_NOWAIT*

Return the total number of bytes actually read which can be less than the total capacity of all the objects.

The operating system may set a limit (*sysconf()* value `'SC_IOV_MAX'`) on the number of buffers that can be used.

Combine the functionality of *os.readv()* and *os.pread()*.

Availability: Linux 2.6.30 and newer, FreeBSD 6.0 and newer, OpenBSD 2.7 and newer. Using flags requires Linux 4.6 or newer.

New in version 3.7.

os.RWF_NOWAIT
Do not wait for data which is not immediately available. If this flag is specified, the system call will return instantly if it would have to read data from the backing storage or wait for a lock.

If some data was successfully read, it will return the number of bytes read. If no bytes were read, it will return `-1` and set errno to *errno.EAGAIN*.

Availability: Linux 4.14 and newer.

New in version 3.7.

os.RWF_HIPRI
High priority read/write. Allows block-based filesystems to use polling of the device, which provides lower latency, but may use additional resources.

Currently, on Linux, this feature is usable only on a file descriptor opened using the *O_DIRECT* flag.

Availability: Linux 4.6 and newer.

New in version 3.7.

os.pwrite(*fd*, *str*, *offset*)
Write the bytestring in *str* to file descriptor *fd* at position of *offset*, leaving the file offset unchanged.

Return the number of bytes actually written.

Availability: Unix.

New in version 3.3.

os.**pwritev**(*fd*, *buffers*, *offset*, *flags=0*)

Write the *buffers* contents to file descriptor *fd* at a offset *offset*, leaving the file offset unchanged. *buffers* must be a sequence of *bytes-like objects*. Buffers are processed in array order. Entire contents of the first buffer is written before proceeding to the second, and so on.

The flags argument contains a bitwise OR of zero or more of the following flags:

- *RWF_DSYNC*
- *RWF_SYNC*

Return the total number of bytes actually written.

The operating system may set a limit (*sysconf()* value `'SC_IOV_MAX'`) on the number of buffers that can be used.

Combine the functionality of *os.writev()* and *os.pwrite()*.

Availability: Linux 2.6.30 and newer, FreeBSD 6.0 and newer, OpenBSD 2.7 and newer. Using flags requires Linux 4.7 or newer.

New in version 3.7.

os.**RWF_DSYNC**

Provide a per-write equivalent of the *O_DSYNC* `open(2)` flag. This flag effect applies only to the data range written by the system call.

Availability: Linux 4.7 and newer.

New in version 3.7.

os.**RWF_SYNC**

Provide a per-write equivalent of the *O_SYNC* `open(2)` flag. This flag effect applies only to the data range written by the system call.

Availability: Linux 4.7 and newer.

New in version 3.7.

os.**read**(*fd*, *n*)

Read at most *n* bytes from file descriptor *fd*.

Return a bytestring containing the bytes read. If the end of the file referred to by *fd* has been reached, an empty bytes object is returned.

Note: This function is intended for low-level I/O and must be applied to a file descriptor as returned by *os.open()* or *pipe()*. To read a "file object" returned by the built-in function *open()* or by *popen()* or *fdopen()*, or *sys.stdin*, use its `read()` or `readline()` methods.

Changed in version 3.5: If the system call is interrupted and the signal handler does not raise an exception, the function now retries the system call instead of raising an *InterruptedError* exception (see **PEP 475** for the rationale).

os.**sendfile**(*out*, *in*, *offset*, *count*)

os.**sendfile**(*out*, *in*, *offset*, *count*[, *headers*][, *trailers*], *flags=0*)

Copy *count* bytes from file descriptor *in* to file descriptor *out* starting at *offset*. Return the number of bytes sent. When EOF is reached return 0.

The first function notation is supported by all platforms that define *sendfile()*.

On Linux, if *offset* is given as `None`, the bytes are read from the current position of *in* and the position of *in* is updated.

The second case may be used on Mac OS X and FreeBSD where *headers* and *trailers* are arbitrary sequences of buffers that are written before and after the data from *in* is written. It returns the same as the first case.

On Mac OS X and FreeBSD, a value of 0 for *count* specifies to send until the end of *in* is reached.

All platforms support sockets as *out* file descriptor, and some platforms allow other types (e.g. regular file, pipe) as well.

Cross-platform applications should not use *headers*, *trailers* and *flags* arguments.

Availability: Unix.

Note: For a higher-level wrapper of *sendfile()*, see *socket.socket.sendfile()*.

New in version 3.3.

os.set_blocking(*fd*, *blocking*)
Set the blocking mode of the specified file descriptor. Set the *O_NONBLOCK* flag if blocking is `False`, clear the flag otherwise.

See also *get_blocking()* and *socket.socket.setblocking()*.

Availability: Unix.

New in version 3.5.

os.SF_NODISKIO
os.SF_MNOWAIT
os.SF_SYNC
Parameters to the *sendfile()* function, if the implementation supports them.

Availability: Unix.

New in version 3.3.

os.readv(*fd*, *buffers*)
Read from a file descriptor *fd* into a number of mutable *bytes-like objects* *buffers*. Transfer data into each buffer until it is full and then move on to the next buffer in the sequence to hold the rest of the data.

Return the total number of bytes actually read which can be less than the total capacity of all the objects.

The operating system may set a limit (*sysconf()* value `'SC_IOV_MAX'`) on the number of buffers that can be used.

Availability: Unix.

New in version 3.3.

os.tcgetpgrp(*fd*)
Return the process group associated with the terminal given by *fd* (an open file descriptor as returned by *os.open()*).

Availability: Unix.

os.tcsetpgrp(*fd*, *pg*)
Set the process group associated with the terminal given by *fd* (an open file descriptor as returned by *os.open()*) to *pg*.

Availability: Unix.

os.**ttyname**(*fd*)
Return a string which specifies the terminal device associated with file descriptor *fd*. If *fd* is not associated with a terminal device, an exception is raised.

Availability: Unix.

os.**write**(*fd*, *str*)
Write the bytestring in *str* to file descriptor *fd*.

Return the number of bytes actually written.

Note: This function is intended for low-level I/O and must be applied to a file descriptor as returned by *os.open()* or *pipe()*. To write a "file object" returned by the built-in function *open()* or by *popen()* or *fdopen()*, or *sys.stdout* or *sys.stderr*, use its `write()` method.

Changed in version 3.5: If the system call is interrupted and the signal handler does not raise an exception, the function now retries the system call instead of raising an *InterruptedError* exception (see **PEP 475** for the rationale).

os.**writev**(*fd*, *buffers*)
Write the contents of *buffers* to file descriptor *fd*. *buffers* must be a sequence of *bytes-like objects*. Buffers are processed in array order. Entire contents of the first buffer is written before proceeding to the second, and so on.

Returns the total number of bytes actually written.

The operating system may set a limit (*sysconf()* value `'SC_IOV_MAX'`) on the number of buffers that can be used.

Availability: Unix.

New in version 3.3.

Querying the size of a terminal

New in version 3.3.

os.**get_terminal_size**(*fd=STDOUT_FILENO*)
Return the size of the terminal window as `(columns, lines)`, tuple of type *terminal_size*.

The optional argument `fd` (default `STDOUT_FILENO`, or standard output) specifies which file descriptor should be queried.

If the file descriptor is not connected to a terminal, an *OSError* is raised.

shutil.get_terminal_size() is the high-level function which should normally be used, `os.get_terminal_size` is the low-level implementation.

Availability: Unix, Windows.

class os.**terminal_size**
A subclass of tuple, holding `(columns, lines)` of the terminal window size.

columns
Width of the terminal window in characters.

lines
Height of the terminal window in characters.

Inheritance of File Descriptors

New in version 3.4.

A file descriptor has an "inheritable" flag which indicates if the file descriptor can be inherited by child processes. Since Python 3.4, file descriptors created by Python are non-inheritable by default.

On UNIX, non-inheritable file descriptors are closed in child processes at the execution of a new program, other file descriptors are inherited.

On Windows, non-inheritable handles and file descriptors are closed in child processes, except for standard streams (file descriptors 0, 1 and 2: stdin, stdout and stderr), which are always inherited. Using *spawn** functions, all inheritable handles and all inheritable file descriptors are inherited. Using the *subprocess* module, all file descriptors except standard streams are closed, and inheritable handles are only inherited if the *close_fds* parameter is `False`.

`os.get_inheritable(`*fd*`)`
Get the "inheritable" flag of the specified file descriptor (a boolean).

`os.set_inheritable(`*fd*, *inheritable*`)`
Set the "inheritable" flag of the specified file descriptor.

`os.get_handle_inheritable(`*handle*`)`
Get the "inheritable" flag of the specified handle (a boolean).

Availability: Windows.

`os.set_handle_inheritable(`*handle*, *inheritable*`)`
Set the "inheritable" flag of the specified handle.

Availability: Windows.

16.1.5 Files and Directories

On some Unix platforms, many of these functions support one or more of these features:

- **specifying a file descriptor:** For some functions, the *path* argument can be not only a string giving a path name, but also a file descriptor. The function will then operate on the file referred to by the descriptor. (For POSIX systems, Python will call the `f...` version of the function.)

  You can check whether or not *path* can be specified as a file descriptor on your platform using *os.supports_fd*. If it is unavailable, using it will raise a *NotImplementedError*.

  If the function also supports *dir_fd* or *follow_symlinks* arguments, it is an error to specify one of those when supplying *path* as a file descriptor.

- **paths relative to directory descriptors:** If *dir_fd* is not `None`, it should be a file descriptor referring to a directory, and the path to operate on should be relative; path will then be relative to that directory. If the path is absolute, *dir_fd* is ignored. (For POSIX systems, Python will call the `...at` or `f...at` version of the function.)

  You can check whether or not *dir_fd* is supported on your platform using *os.supports_dir_fd*. If it is unavailable, using it will raise a *NotImplementedError*.

- **not following symlinks:** If *follow_symlinks* is `False`, and the last element of the path to operate on is a symbolic link, the function will operate on the symbolic link itself instead of the file the link points to. (For POSIX systems, Python will call the `l...` version of the function.)

  You can check whether or not *follow_symlinks* is supported on your platform using *os.supports_follow_symlinks*. If it is unavailable, using it will raise a *NotImplementedError*.

os.access(*path*, *mode*, ***, *dir_fd=None*, *effective_ids=False*, *follow_symlinks=True*)

Use the real uid/gid to test for access to *path*. Note that most operations will use the effective uid/gid, therefore this routine can be used in a suid/sgid environment to test if the invoking user has the specified access to *path*. *mode* should be *F_OK* to test the existence of *path*, or it can be the inclusive OR of one or more of *R_OK*, *W_OK*, and *X_OK* to test permissions. Return *True* if access is allowed, *False* if not. See the Unix man page *access(2)* for more information.

This function can support specifying *paths relative to directory descriptors* and *not following symlinks*.

If *effective_ids* is `True`, *access()* will perform its access checks using the effective uid/gid instead of the real uid/gid. *effective_ids* may not be supported on your platform; you can check whether or not it is available using *os.supports_effective_ids*. If it is unavailable, using it will raise a *NotImplementedError*.

Note: Using *access()* to check if a user is authorized to e.g. open a file before actually doing so using *open()* creates a security hole, because the user might exploit the short time interval between checking and opening the file to manipulate it. It's preferable to use *EAFP* techniques. For example:

```
if os.access("myfile", os.R_OK):
    with open("myfile") as fp:
        return fp.read()
return "some default data"
```

is better written as:

```
try:
    fp = open("myfile")
except PermissionError:
    return "some default data"
else:
    with fp:
        return fp.read()
```

Note: I/O operations may fail even when *access()* indicates that they would succeed, particularly for operations on network filesystems which may have permissions semantics beyond the usual POSIX permission-bit model.

Changed in version 3.3: Added the *dir_fd*, *effective_ids*, and *follow_symlinks* parameters.

Changed in version 3.6: Accepts a *path-like object*.

os.F_OK
os.R_OK
os.W_OK
os.X_OK

Values to pass as the *mode* parameter of *access()* to test the existence, readability, writability and executability of *path*, respectively.

os.chdir(*path*)

Change the current working directory to *path*.

This function can support *specifying a file descriptor*. The descriptor must refer to an opened directory, not an open file.

New in version 3.3: Added support for specifying *path* as a file descriptor on some platforms.

Changed in version 3.6: Accepts a *path-like object*.

os.**chflags**(*path*, *flags*, ***, *follow_symlinks=True*)

Set the flags of *path* to the numeric *flags*. *flags* may take a combination (bitwise OR) of the following values (as defined in the *stat* module):

- *stat.UF_NODUMP*
- *stat.UF_IMMUTABLE*
- *stat.UF_APPEND*
- *stat.UF_OPAQUE*
- *stat.UF_NOUNLINK*
- *stat.UF_COMPRESSED*
- *stat.UF_HIDDEN*
- *stat.SF_ARCHIVED*
- *stat.SF_IMMUTABLE*
- *stat.SF_APPEND*
- *stat.SF_NOUNLINK*
- *stat.SF_SNAPSHOT*

This function can support *not following symlinks*.

Availability: Unix.

New in version 3.3: The *follow_symlinks* argument.

Changed in version 3.6: Accepts a *path-like object*.

os.**chmod**(*path*, *mode*, ***, *dir_fd=None*, *follow_symlinks=True*)

Change the mode of *path* to the numeric *mode*. *mode* may take one of the following values (as defined in the *stat* module) or bitwise ORed combinations of them:

- *stat.S_ISUID*
- *stat.S_ISGID*
- *stat.S_ENFMT*
- *stat.S_ISVTX*
- *stat.S_IREAD*
- *stat.S_IWRITE*
- *stat.S_IEXEC*
- *stat.S_IRWXU*
- *stat.S_IRUSR*
- *stat.S_IWUSR*
- *stat.S_IXUSR*
- *stat.S_IRWXG*
- *stat.S_IRGRP*
- *stat.S_IWGRP*
- *stat.S_IXGRP*
- *stat.S_IRWXO*
- *stat.S_IROTH*

- *stat.S_IWOTH*
- *stat.S_IXOTH*

This function can support *specifying a file descriptor*, *paths relative to directory descriptors* and *not following symlinks*.

Note: Although Windows supports *chmod()*, you can only set the file's read-only flag with it (via the `stat.S_IWRITE` and `stat.S_IREAD` constants or a corresponding integer value). All other bits are ignored.

New in version 3.3: Added support for specifying *path* as an open file descriptor, and the *dir_fd* and *follow_symlinks* arguments.

Changed in version 3.6: Accepts a *path-like object*.

`os.chown`(*path*, *uid*, *gid*, ***, *dir_fd=None*, *follow_symlinks=True*)
Change the owner and group id of *path* to the numeric *uid* and *gid*. To leave one of the ids unchanged, set it to -1.

This function can support *specifying a file descriptor*, *paths relative to directory descriptors* and *not following symlinks*.

See *shutil.chown()* for a higher-level function that accepts names in addition to numeric ids.

Availability: Unix.

New in version 3.3: Added support for specifying an open file descriptor for *path*, and the *dir_fd* and *follow_symlinks* arguments.

Changed in version 3.6: Supports a *path-like object*.

`os.chroot`(*path*)
Change the root directory of the current process to *path*.

Availability: Unix.

Changed in version 3.6: Accepts a *path-like object*.

`os.fchdir`(*fd*)
Change the current working directory to the directory represented by the file descriptor *fd*. The descriptor must refer to an opened directory, not an open file. As of Python 3.3, this is equivalent to `os.chdir(fd)`.

Availability: Unix.

`os.getcwd`()
Return a string representing the current working directory.

`os.getcwdb`()
Return a bytestring representing the current working directory.

`os.lchflags`(*path*, *flags*)
Set the flags of *path* to the numeric *flags*, like *chflags()*, but do not follow symbolic links. As of Python 3.3, this is equivalent to `os.chflags(path, flags, follow_symlinks=False)`.

Availability: Unix.

Changed in version 3.6: Accepts a *path-like object*.

`os.lchmod`(*path*, *mode*)
Change the mode of *path* to the numeric *mode*. If path is a symlink, this affects the symlink rather than the target. See the docs for *chmod()* for possible values of *mode*. As of Python 3.3, this is equivalent to `os.chmod(path, mode, follow_symlinks=False)`.

Availability: Unix.

Changed in version 3.6: Accepts a *path-like object*.

`os.lchown`(*path*, *uid*, *gid*)
Change the owner and group id of *path* to the numeric *uid* and *gid*. This function will not follow symbolic links. As of Python 3.3, this is equivalent to `os.chown(path, uid, gid, follow_symlinks=False)`.

Availability: Unix.

Changed in version 3.6: Accepts a *path-like object*.

`os.link`(*src*, *dst*, ***, *src_dir_fd=None*, *dst_dir_fd=None*, *follow_symlinks=True*)
Create a hard link pointing to *src* named *dst*.

This function can support specifying *src_dir_fd* and/or *dst_dir_fd* to supply *paths relative to directory descriptors*, and *not following symlinks*.

Availability: Unix, Windows.

Changed in version 3.2: Added Windows support.

New in version 3.3: Added the *src_dir_fd*, *dst_dir_fd*, and *follow_symlinks* arguments.

Changed in version 3.6: Accepts a *path-like object* for *src* and *dst*.

`os.listdir`(*path='.'*)
Return a list containing the names of the entries in the directory given by *path*. The list is in arbitrary order, and does not include the special entries `'.'` and `'..'` even if they are present in the directory.

path may be a *path-like object*. If *path* is of type `bytes` (directly or indirectly through the *PathLike* interface), the filenames returned will also be of type `bytes`; in all other circumstances, they will be of type `str`.

This function can also support *specifying a file descriptor*; the file descriptor must refer to a directory.

Note: To encode `str` filenames to `bytes`, use *fsencode()*.

See also:

The *scandir()* function returns directory entries along with file attribute information, giving better performance for many common use cases.

Changed in version 3.2: The *path* parameter became optional.

New in version 3.3: Added support for specifying an open file descriptor for *path*.

Changed in version 3.6: Accepts a *path-like object*.

`os.lstat`(*path*, ***, *dir_fd=None*)
Perform the equivalent of an `lstat()` system call on the given path. Similar to *stat()*, but does not follow symbolic links. Return a *stat_result* object.

On platforms that do not support symbolic links, this is an alias for *stat()*.

As of Python 3.3, this is equivalent to `os.stat(path, dir_fd=dir_fd, follow_symlinks=False)`.

This function can also support *paths relative to directory descriptors*.

See also:

The *stat()* function.

Changed in version 3.2: Added support for Windows 6.0 (Vista) symbolic links.

Changed in version 3.3: Added the *dir_fd* parameter.

Changed in version 3.6: Accepts a *path-like object* for *src* and *dst*.

os.mkdir(*path*, *mode=0o777*, ***, *dir_fd=None*)
Create a directory named *path* with numeric mode *mode*.

If the directory already exists, *FileExistsError* is raised.

On some systems, *mode* is ignored. Where it is used, the current umask value is first masked out. If bits other than the last 9 (i.e. the last 3 digits of the octal representation of the *mode*) are set, their meaning is platform-dependent. On some platforms, they are ignored and you should call *chmod()* explicitly to set them.

This function can also support *paths relative to directory descriptors*.

It is also possible to create temporary directories; see the *tempfile* module's *tempfile.mkdtemp()* function.

New in version 3.3: The *dir_fd* argument.

Changed in version 3.6: Accepts a *path-like object*.

os.makedirs(*name*, *mode=0o777*, *exist_ok=False*)
Recursive directory creation function. Like *mkdir()*, but makes all intermediate-level directories needed to contain the leaf directory.

The *mode* parameter is passed to *mkdir()* for creating the leaf directory; see *the mkdir() description* for how it is interpreted. To set the file permission bits of any newly-created parent directories you can set the umask before invoking *makedirs()*. The file permission bits of existing parent directories are not changed.

If *exist_ok* is `False` (the default), an *OSError* is raised if the target directory already exists.

Note: *makedirs()* will become confused if the path elements to create include *pardir* (eg. ".." on UNIX systems).

This function handles UNC paths correctly.

New in version 3.2: The *exist_ok* parameter.

Changed in version 3.4.1: Before Python 3.4.1, if *exist_ok* was `True` and the directory existed, *makedirs()* would still raise an error if *mode* did not match the mode of the existing directory. Since this behavior was impossible to implement safely, it was removed in Python 3.4.1. See bpo-21082.

Changed in version 3.6: Accepts a *path-like object*.

Changed in version 3.7: The *mode* argument no longer affects the file permission bits of newly-created intermediate-level directories.

os.mkfifo(*path*, *mode=0o666*, ***, *dir_fd=None*)
Create a FIFO (a named pipe) named *path* with numeric mode *mode*. The current umask value is first masked out from the mode.

This function can also support *paths relative to directory descriptors*.

FIFOs are pipes that can be accessed like regular files. FIFOs exist until they are deleted (for example with *os.unlink()*). Generally, FIFOs are used as rendezvous between "client" and "server" type processes: the server opens the FIFO for reading, and the client opens it for writing. Note that *mkfifo()* doesn't open the FIFO — it just creates the rendezvous point.

Availability: Unix.

New in version 3.3: The *dir_fd* argument.

Changed in version 3.6: Accepts a *path-like object*.

os.**mknod**(*path*, *mode=0o600*, *device=0*, ***, *dir_fd=None*)
Create a filesystem node (file, device special file or named pipe) named *path*. *mode* specifies both the permissions to use and the type of node to be created, being combined (bitwise OR) with one of `stat.S_IFREG`, `stat.S_IFCHR`, `stat.S_IFBLK`, and `stat.S_IFIFO` (those constants are available in *stat*). For `stat.S_IFCHR` and `stat.S_IFBLK`, *device* defines the newly created device special file (probably using *os.makedev()*), otherwise it is ignored.

This function can also support *paths relative to directory descriptors*.

Availability: Unix.

New in version 3.3: The *dir_fd* argument.

Changed in version 3.6: Accepts a *path-like object*.

os.**major**(*device*)
Extract the device major number from a raw device number (usually the `st_dev` or `st_rdev` field from `stat`).

os.**minor**(*device*)
Extract the device minor number from a raw device number (usually the `st_dev` or `st_rdev` field from `stat`).

os.**makedev**(*major*, *minor*)
Compose a raw device number from the major and minor device numbers.

os.**pathconf**(*path*, *name*)
Return system configuration information relevant to a named file. *name* specifies the configuration value to retrieve; it may be a string which is the name of a defined system value; these names are specified in a number of standards (POSIX.1, Unix 95, Unix 98, and others). Some platforms define additional names as well. The names known to the host operating system are given in the `pathconf_names` dictionary. For configuration variables not included in that mapping, passing an integer for *name* is also accepted.

If *name* is a string and is not known, *ValueError* is raised. If a specific value for *name* is not supported by the host system, even if it is included in `pathconf_names`, an *OSError* is raised with *errno.EINVAL* for the error number.

This function can support *specifying a file descriptor*.

Availability: Unix.

Changed in version 3.6: Accepts a *path-like object*.

os.**pathconf_names**
Dictionary mapping names accepted by *pathconf()* and *fpathconf()* to the integer values defined for those names by the host operating system. This can be used to determine the set of names known to the system.

Availability: Unix.

os.**readlink**(*path*, ***, *dir_fd=None*)
Return a string representing the path to which the symbolic link points. The result may be either an absolute or relative pathname; if it is relative, it may be converted to an absolute pathname using `os.path.join(os.path.dirname(path), result)`.

If the *path* is a string object (directly or indirectly through a *PathLike* interface), the result will also be a string object, and the call may raise a UnicodeDecodeError. If the *path* is a bytes object (direct or indirectly), the result will be a bytes object.

This function can also support *paths relative to directory descriptors*.

Availability: Unix, Windows

Changed in version 3.2: Added support for Windows 6.0 (Vista) symbolic links.

New in version 3.3: The *dir_fd* argument.

Changed in version 3.6: Accepts a *path-like object*.

os.remove(*path*, ***, *dir_fd=None*)
Remove (delete) the file *path*. If *path* is a directory, *OSError* is raised. Use *rmdir()* to remove directories.

This function can support *paths relative to directory descriptors*.

On Windows, attempting to remove a file that is in use causes an exception to be raised; on Unix, the directory entry is removed but the storage allocated to the file is not made available until the original file is no longer in use.

This function is semantically identical to *unlink()*.

New in version 3.3: The *dir_fd* argument.

Changed in version 3.6: Accepts a *path-like object*.

os.removedirs(*name*)
Remove directories recursively. Works like *rmdir()* except that, if the leaf directory is successfully removed, *removedirs()* tries to successively remove every parent directory mentioned in *path* until an error is raised (which is ignored, because it generally means that a parent directory is not empty). For example, `os.removedirs('foo/bar/baz')` will first remove the directory `'foo/bar/baz'`, and then remove `'foo/bar'` and `'foo'` if they are empty. Raises *OSError* if the leaf directory could not be successfully removed.

Changed in version 3.6: Accepts a *path-like object*.

os.rename(*src*, *dst*, ***, *src_dir_fd=None*, *dst_dir_fd=None*)
Rename the file or directory *src* to *dst*. If *dst* is a directory, *OSError* will be raised. On Unix, if *dst* exists and is a file, it will be replaced silently if the user has permission. The operation may fail on some Unix flavors if *src* and *dst* are on different filesystems. If successful, the renaming will be an atomic operation (this is a POSIX requirement). On Windows, if *dst* already exists, *OSError* will be raised even if it is a file.

This function can support specifying *src_dir_fd* and/or *dst_dir_fd* to supply *paths relative to directory descriptors*.

If you want cross-platform overwriting of the destination, use *replace()*.

New in version 3.3: The *src_dir_fd* and *dst_dir_fd* arguments.

Changed in version 3.6: Accepts a *path-like object* for *src* and *dst*.

os.renames(*old*, *new*)
Recursive directory or file renaming function. Works like *rename()*, except creation of any intermediate directories needed to make the new pathname good is attempted first. After the rename, directories corresponding to rightmost path segments of the old name will be pruned away using *removedirs()*.

Note: This function can fail with the new directory structure made if you lack permissions needed to remove the leaf directory or file.

Changed in version 3.6: Accepts a *path-like object* for *old* and *new*.

os.replace(*src*, *dst*, ***, *src_dir_fd=None*, *dst_dir_fd=None*)
Rename the file or directory *src* to *dst*. If *dst* is a directory, *OSError* will be raised. If *dst* exists and is a file, it will be replaced silently if the user has permission. The operation may fail if *src* and *dst* are on different filesystems. If successful, the renaming will be an atomic operation (this is a POSIX requirement).

This function can support specifying *src_dir_fd* and/or *dst_dir_fd* to supply *paths relative to directory descriptors*.

New in version 3.3.

Changed in version 3.6: Accepts a *path-like object* for *src* and *dst*.

os.rmdir(*path*, ***, *dir_fd=None*)

Remove (delete) the directory *path*. Only works when the directory is empty, otherwise, *OSError* is raised. In order to remove whole directory trees, *shutil.rmtree()* can be used.

This function can support *paths relative to directory descriptors*.

New in version 3.3: The *dir_fd* parameter.

Changed in version 3.6: Accepts a *path-like object*.

os.scandir(*path='.'*)

Return an iterator of *os.DirEntry* objects corresponding to the entries in the directory given by *path*. The entries are yielded in arbitrary order, and the special entries `'.'` and `'..'` are not included.

Using *scandir()* instead of *listdir()* can significantly increase the performance of code that also needs file type or file attribute information, because *os.DirEntry* objects expose this information if the operating system provides it when scanning a directory. All *os.DirEntry* methods may perform a system call, but *is_dir()* and *is_file()* usually only require a system call for symbolic links; *os.DirEntry.stat()* always requires a system call on Unix but only requires one for symbolic links on Windows.

path may be a *path-like object*. If *path* is of type `bytes` (directly or indirectly through the *PathLike* interface), the type of the *name* and *path* attributes of each *os.DirEntry* will be `bytes`; in all other circumstances, they will be of type `str`.

This function can also support *specifying a file descriptor*; the file descriptor must refer to a directory.

The *scandir()* iterator supports the *context manager* protocol and has the following method:

scandir.close()

Close the iterator and free acquired resources.

This is called automatically when the iterator is exhausted or garbage collected, or when an error happens during iterating. However it is advisable to call it explicitly or use the `with` statement.

New in version 3.6.

The following example shows a simple use of *scandir()* to display all the files (excluding directories) in the given *path* that don't start with `'.'`. The `entry.is_file()` call will generally not make an additional system call:

```
with os.scandir(path) as it:
    for entry in it:
        if not entry.name.startswith('.') and entry.is_file():
            print(entry.name)
```

Note: On Unix-based systems, *scandir()* uses the system's opendir() and readdir() functions. On Windows, it uses the Win32 FindFirstFileW and FindNextFileW functions.

New in version 3.5.

New in version 3.6: Added support for the *context manager* protocol and the *close()* method. If a *scandir()* iterator is neither exhausted nor explicitly closed a *ResourceWarning* will be emitted in its destructor.

The function accepts a *path-like object*.

Changed in version 3.7: Added support for *file descriptors* on Unix.

class os.DirEntry

Object yielded by *scandir()* to expose the file path and other file attributes of a directory entry.

scandir() will provide as much of this information as possible without making additional system calls. When a `stat()` or `lstat()` system call is made, the `os.DirEntry` object will cache the result.

`os.DirEntry` instances are not intended to be stored in long-lived data structures; if you know the file metadata has changed or if a long time has elapsed since calling *scandir()*, call `os.stat(entry.path)` to fetch up-to-date information.

Because the `os.DirEntry` methods can make operating system calls, they may also raise *OSError*. If you need very fine-grained control over errors, you can catch *OSError* when calling one of the `os.DirEntry` methods and handle as appropriate.

To be directly usable as a *path-like object*, `os.DirEntry` implements the *PathLike* interface.

Attributes and methods on a `os.DirEntry` instance are as follows:

name

The entry's base filename, relative to the *scandir()* *path* argument.

The *name* attribute will be `bytes` if the *scandir()* *path* argument is of type `bytes` and `str` otherwise. Use *fsdecode()* to decode byte filenames.

path

The entry's full path name: equivalent to `os.path.join(scandir_path, entry.name)` where *scandir_path* is the *scandir()* *path* argument. The path is only absolute if the *scandir()* *path* argument was absolute. If the *scandir()* *path* argument was a *file descriptor*, the *path* attribute is the same as the *name* attribute.

The *path* attribute will be `bytes` if the *scandir()* *path* argument is of type `bytes` and `str` otherwise. Use *fsdecode()* to decode byte filenames.

inode()

Return the inode number of the entry.

The result is cached on the `os.DirEntry` object. Use `os.stat(entry.path, follow_symlinks=False).st_ino` to fetch up-to-date information.

On the first, uncached call, a system call is required on Windows but not on Unix.

is_dir(**, follow_symlinks=True*)

Return `True` if this entry is a directory or a symbolic link pointing to a directory; return `False` if the entry is or points to any other kind of file, or if it doesn't exist anymore.

If *follow_symlinks* is `False`, return `True` only if this entry is a directory (without following symlinks); return `False` if the entry is any other kind of file or if it doesn't exist anymore.

The result is cached on the `os.DirEntry` object, with a separate cache for *follow_symlinks* `True` and `False`. Call *os.stat()* along with *stat.S_ISDIR()* to fetch up-to-date information.

On the first, uncached call, no system call is required in most cases. Specifically, for non-symlinks, neither Windows or Unix require a system call, except on certain Unix file systems, such as network file systems, that return `dirent.d_type == DT_UNKNOWN`. If the entry is a symlink, a system call will be required to follow the symlink unless *follow_symlinks* is `False`.

This method can raise *OSError*, such as *PermissionError*, but *FileNotFoundError* is caught and not raised.

is_file(**, follow_symlinks=True*)

Return `True` if this entry is a file or a symbolic link pointing to a file; return `False` if the entry is or points to a directory or other non-file entry, or if it doesn't exist anymore.

If *follow_symlinks* is `False`, return `True` only if this entry is a file (without following symlinks); return `False` if the entry is a directory or other non-file entry, or if it doesn't exist anymore.

The result is cached on the `os.DirEntry` object. Caching, system calls made, and exceptions raised are as per *is_dir()*.

`is_symlink()`
Return `True` if this entry is a symbolic link (even if broken); return `False` if the entry points to a directory or any kind of file, or if it doesn't exist anymore.

The result is cached on the `os.DirEntry` object. Call *os.path.islink()* to fetch up-to-date information.

On the first, uncached call, no system call is required in most cases. Specifically, neither Windows or Unix require a system call, except on certain Unix file systems, such as network file systems, that return `dirent.d_type == DT_UNKNOWN`.

This method can raise *OSError*, such as *PermissionError*, but *FileNotFoundError* is caught and not raised.

`stat`(**, follow_symlinks=True*)
Return a *stat_result* object for this entry. This method follows symbolic links by default; to stat a symbolic link add the `follow_symlinks=False` argument.

On Unix, this method always requires a system call. On Windows, it only requires a system call if *follow_symlinks* is `True` and the entry is a symbolic link.

On Windows, the `st_ino`, `st_dev` and `st_nlink` attributes of the *stat_result* are always set to zero. Call *os.stat()* to get these attributes.

The result is cached on the `os.DirEntry` object, with a separate cache for *follow_symlinks* `True` and `False`. Call *os.stat()* to fetch up-to-date information.

Note that there is a nice correspondence between several attributes and methods of `os.DirEntry` and of *pathlib.Path*. In particular, the `name` attribute has the same meaning, as do the `is_dir()`, `is_file()`, `is_symlink()` and `stat()` methods.

New in version 3.5.

Changed in version 3.6: Added support for the *PathLike* interface. Added support for *bytes* paths on Windows.

`os.stat`(*path*, ***, *dir_fd=None*, *follow_symlinks=True*)
Get the status of a file or a file descriptor. Perform the equivalent of a `stat()` system call on the given path. *path* may be specified as either a string or bytes – directly or indirectly through the *PathLike* interface – or as an open file descriptor. Return a *stat_result* object.

This function normally follows symlinks; to stat a symlink add the argument `follow_symlinks=False`, or use *lstat()*.

This function can support *specifying a file descriptor* and *not following symlinks*.

Example:

```
>>> import os
>>> statinfo = os.stat('somefile.txt')
>>> statinfo
os.stat_result(st_mode=33188, st_ino=7876932, st_dev=234881026,
st_nlink=1, st_uid=501, st_gid=501, st_size=264, st_atime=1297230295,
st_mtime=1297230027, st_ctime=1297230027)
>>> statinfo.st_size
264
```

See also:

fstat() and *lstat()* functions.

New in version 3.3: Added the *dir_fd* and *follow_symlinks* arguments, specifying a file descriptor instead of a path.

Changed in version 3.6: Accepts a *path-like object*.

class os.stat_result

Object whose attributes correspond roughly to the members of the `stat` structure. It is used for the result of *os.stat()*, *os.fstat()* and *os.lstat()*.

Attributes:

st_mode
File mode: file type and file mode bits (permissions).

st_ino
Platform dependent, but if non-zero, uniquely identifies the file for a given value of `st_dev`. Typically:

- the inode number on Unix,
- the file index on Windows

st_dev
Identifier of the device on which this file resides.

st_nlink
Number of hard links.

st_uid
User identifier of the file owner.

st_gid
Group identifier of the file owner.

st_size
Size of the file in bytes, if it is a regular file or a symbolic link. The size of a symbolic link is the length of the pathname it contains, without a terminating null byte.

Timestamps:

st_atime
Time of most recent access expressed in seconds.

st_mtime
Time of most recent content modification expressed in seconds.

st_ctime
Platform dependent:

- the time of most recent metadata change on Unix,
- the time of creation on Windows, expressed in seconds.

st_atime_ns
Time of most recent access expressed in nanoseconds as an integer.

st_mtime_ns
Time of most recent content modification expressed in nanoseconds as an integer.

st_ctime_ns
Platform dependent:

- the time of most recent metadata change on Unix,

- the time of creation on Windows, expressed in nanoseconds as an integer.

Note: The exact meaning and resolution of the *st_atime*, *st_mtime*, and *st_ctime* attributes depend on the operating system and the file system. For example, on Windows systems using the FAT or FAT32 file systems, *st_mtime* has 2-second resolution, and *st_atime* has only 1-day resolution. See your operating system documentation for details.

Similarly, although *st_atime_ns*, *st_mtime_ns*, and *st_ctime_ns* are always expressed in nanoseconds, many systems do not provide nanosecond precision. On systems that do provide nanosecond precision, the floating-point object used to store *st_atime*, *st_mtime*, and *st_ctime* cannot preserve all of it, and as such will be slightly inexact. If you need the exact timestamps you should always use *st_atime_ns*, *st_mtime_ns*, and *st_ctime_ns*.

On some Unix systems (such as Linux), the following attributes may also be available:

st_blocks
Number of 512-byte blocks allocated for file. This may be smaller than *st_size*/512 when the file has holes.

st_blksize
"Preferred" blocksize for efficient file system I/O. Writing to a file in smaller chunks may cause an inefficient read-modify-rewrite.

st_rdev
Type of device if an inode device.

st_flags
User defined flags for file.

On other Unix systems (such as FreeBSD), the following attributes may be available (but may be only filled out if root tries to use them):

st_gen
File generation number.

st_birthtime
Time of file creation.

On Solaris and derivatives, the following attributes may also be available:

st_fstype
String that uniquely identifies the type of the filesystem that contains the file.

On Mac OS systems, the following attributes may also be available:

st_rsize
Real size of the file.

st_creator
Creator of the file.

st_type
File type.

On Windows systems, the following attribute is also available:

st_file_attributes
Windows file attributes: `dwFileAttributes` member of the `BY_HANDLE_FILE_INFORMATION` structure returned by `GetFileInformationByHandle()`. See the `FILE_ATTRIBUTE_*` constants in the *stat* module.

The standard module *stat* defines functions and constants that are useful for extracting information from a `stat` structure. (On Windows, some items are filled with dummy values.)

For backward compatibility, a *stat_result* instance is also accessible as a tuple of at least 10 integers giving the most important (and portable) members of the `stat` structure, in the order *st_mode*, *st_ino*, *st_dev*, *st_nlink*, *st_uid*, *st_gid*, *st_size*, *st_atime*, *st_mtime*, *st_ctime*. More items may be added at the end by some implementations. For compatibility with older Python versions, accessing *stat_result* as a tuple always returns integers.

New in version 3.3: Added the *st_atime_ns*, *st_mtime_ns*, and *st_ctime_ns* members.

New in version 3.5: Added the *st_file_attributes* member on Windows.

Changed in version 3.5: Windows now returns the file index as *st_ino* when available.

New in version 3.7: Added the *st_fstype* member to Solaris/derivatives.

os.statvfs(*path*)

Perform a `statvfs()` system call on the given path. The return value is an object whose attributes describe the filesystem on the given path, and correspond to the members of the `statvfs` structure, namely: `f_bsize`, `f_frsize`, `f_blocks`, `f_bfree`, `f_bavail`, `f_files`, `f_ffree`, `f_favail`, `f_flag`, `f_namemax`, `f_fsid`.

Two module-level constants are defined for the `f_flag` attribute's bit-flags: if `ST_RDONLY` is set, the filesystem is mounted read-only, and if `ST_NOSUID` is set, the semantics of setuid/setgid bits are disabled or not supported.

Additional module-level constants are defined for GNU/glibc based systems. These are `ST_NODEV` (disallow access to device special files), `ST_NOEXEC` (disallow program execution), `ST_SYNCHRONOUS` (writes are synced at once), `ST_MANDLOCK` (allow mandatory locks on an FS), `ST_WRITE` (write on file/directory/symlink), `ST_APPEND` (append-only file), `ST_IMMUTABLE` (immutable file), `ST_NOATIME` (do not update access times), `ST_NODIRATIME` (do not update directory access times), `ST_RELATIME` (update atime relative to mtime/ctime).

This function can support *specifying a file descriptor*.

Availability: Unix.

Changed in version 3.2: The `ST_RDONLY` and `ST_NOSUID` constants were added.

New in version 3.3: Added support for specifying an open file descriptor for *path*.

Changed in version 3.4: The `ST_NODEV`, `ST_NOEXEC`, `ST_SYNCHRONOUS`, `ST_MANDLOCK`, `ST_WRITE`, `ST_APPEND`, `ST_IMMUTABLE`, `ST_NOATIME`, `ST_NODIRATIME`, and `ST_RELATIME` constants were added.

Changed in version 3.6: Accepts a *path-like object*.

New in version 3.7: Added `f_fsid`.

os.supports_dir_fd

A *Set* object indicating which functions in the *os* module permit use of their *dir_fd* parameter. Different platforms provide different functionality, and an option that might work on one might be unsupported on another. For consistency's sakes, functions that support *dir_fd* always allow specifying the parameter, but will raise an exception if the functionality is not actually available.

To check whether a particular function permits use of its *dir_fd* parameter, use the `in` operator on `supports_dir_fd`. As an example, this expression determines whether the *dir_fd* parameter of *os.stat()* is locally available:

```
os.stat in os.supports_dir_fd
```

Currently *dir_fd* parameters only work on Unix platforms; none of them work on Windows.

New in version 3.3.

os.supports_effective_ids

A *Set* object indicating which functions in the *os* module permit use of the *effective_ids* parameter

for *os.access()*. If the local platform supports it, the collection will contain *os.access()*, otherwise it will be empty.

To check whether you can use the *effective_ids* parameter for *os.access()*, use the `in` operator on `supports_effective_ids`, like so:

```
os.access in os.supports_effective_ids
```

Currently *effective_ids* only works on Unix platforms; it does not work on Windows.

New in version 3.3.

os.supports_fd

A *Set* object indicating which functions in the *os* module permit specifying their *path* parameter as an open file descriptor. Different platforms provide different functionality, and an option that might work on one might be unsupported on another. For consistency's sakes, functions that support *fd* always allow specifying the parameter, but will raise an exception if the functionality is not actually available.

To check whether a particular function permits specifying an open file descriptor for its *path* parameter, use the `in` operator on `supports_fd`. As an example, this expression determines whether *os.chdir()* accepts open file descriptors when called on your local platform:

```
os.chdir in os.supports_fd
```

New in version 3.3.

os.supports_follow_symlinks

A *Set* object indicating which functions in the *os* module permit use of their *follow_symlinks* parameter. Different platforms provide different functionality, and an option that might work on one might be unsupported on another. For consistency's sakes, functions that support *follow_symlinks* always allow specifying the parameter, but will raise an exception if the functionality is not actually available.

To check whether a particular function permits use of its *follow_symlinks* parameter, use the `in` operator on `supports_follow_symlinks`. As an example, this expression determines whether the *follow_symlinks* parameter of *os.stat()* is locally available:

```
os.stat in os.supports_follow_symlinks
```

New in version 3.3.

os.symlink(*src*, *dst*, *target_is_directory=False*, ***, *dir_fd=None*)

Create a symbolic link pointing to *src* named *dst*.

On Windows, a symlink represents either a file or a directory, and does not morph to the target dynamically. If the target is present, the type of the symlink will be created to match. Otherwise, the symlink will be created as a directory if *target_is_directory* is `True` or a file symlink (the default) otherwise. On non-Window platforms, *target_is_directory* is ignored.

Symbolic link support was introduced in Windows 6.0 (Vista). *symlink()* will raise a *NotImplementedError* on Windows versions earlier than 6.0.

This function can support *paths relative to directory descriptors*.

Note: On Windows, the *SeCreateSymbolicLinkPrivilege* is required in order to successfully create symlinks. This privilege is not typically granted to regular users but is available to accounts which can escalate privileges to the administrator level. Either obtaining the privilege or running your application as an administrator are ways to successfully create symlinks.

OSError is raised when the function is called by an unprivileged user.

Availability: Unix, Windows.

Changed in version 3.2: Added support for Windows 6.0 (Vista) symbolic links.

New in version 3.3: Added the *dir_fd* argument, and now allow *target_is_directory* on non-Windows platforms.

Changed in version 3.6: Accepts a *path-like object* for *src* and *dst*.

os.sync()
Force write of everything to disk.

Availability: Unix.

New in version 3.3.

os.truncate(*path*, *length*)
Truncate the file corresponding to *path*, so that it is at most *length* bytes in size.

This function can support *specifying a file descriptor*.

Availability: Unix, Windows.

New in version 3.3.

Changed in version 3.5: Added support for Windows

Changed in version 3.6: Accepts a *path-like object*.

os.unlink(*path*, ***, *dir_fd=None*)
Remove (delete) the file *path*. This function is semantically identical to *remove()*; the `unlink` name is its traditional Unix name. Please see the documentation for *remove()* for further information.

New in version 3.3: The *dir_fd* parameter.

Changed in version 3.6: Accepts a *path-like object*.

os.utime(*path*, *times=None*, ***[, *ns*], *dir_fd=None*, *follow_symlinks=True*)
Set the access and modified times of the file specified by *path*.

utime() takes two optional parameters, *times* and *ns*. These specify the times set on *path* and are used as follows:

- If *ns* is specified, it must be a 2-tuple of the form `(atime_ns, mtime_ns)` where each member is an int expressing nanoseconds.
- If *times* is not `None`, it must be a 2-tuple of the form `(atime, mtime)` where each member is an int or float expressing seconds.
- If *times* is `None` and *ns* is unspecified, this is equivalent to specifying `ns=(atime_ns, mtime_ns)` where both times are the current time.

It is an error to specify tuples for both *times* and *ns*.

Whether a directory can be given for *path* depends on whether the operating system implements directories as files (for example, Windows does not). Note that the exact times you set here may not be returned by a subsequent *stat()* call, depending on the resolution with which your operating system records access and modification times; see *stat()*. The best way to preserve exact times is to use the *st_atime_ns* and *st_mtime_ns* fields from the *os.stat()* result object with the *ns* parameter to *utime*.

This function can support *specifying a file descriptor*, *paths relative to directory descriptors* and *not following symlinks*.

New in version 3.3: Added support for specifying an open file descriptor for *path*, and the *dir_fd*, *follow_symlinks*, and *ns* parameters.

Changed in version 3.6: Accepts a *path-like object*.

os.walk(*top*, *topdown=True*, *onerror=None*, *followlinks=False*)

Generate the file names in a directory tree by walking the tree either top-down or bottom-up. For each directory in the tree rooted at directory *top* (including *top* itself), it yields a 3-tuple `(dirpath, dirnames, filenames)`.

dirpath is a string, the path to the directory. *dirnames* is a list of the names of the subdirectories in *dirpath* (excluding `'.'` and `'..'`). *filenames* is a list of the names of the non-directory files in *dirpath*. Note that the names in the lists contain no path components. To get a full path (which begins with *top*) to a file or directory in *dirpath*, do `os.path.join(dirpath, name)`.

If optional argument *topdown* is `True` or not specified, the triple for a directory is generated before the triples for any of its subdirectories (directories are generated top-down). If *topdown* is `False`, the triple for a directory is generated after the triples for all of its subdirectories (directories are generated bottom-up). No matter the value of *topdown*, the list of subdirectories is retrieved before the tuples for the directory and its subdirectories are generated.

When *topdown* is `True`, the caller can modify the *dirnames* list in-place (perhaps using `del` or slice assignment), and *walk()* will only recurse into the subdirectories whose names remain in *dirnames*; this can be used to prune the search, impose a specific order of visiting, or even to inform *walk()* about directories the caller creates or renames before it resumes *walk()* again. Modifying *dirnames* when *topdown* is `False` has no effect on the behavior of the walk, because in bottom-up mode the directories in *dirnames* are generated before *dirpath* itself is generated.

By default, errors from the *scandir()* call are ignored. If optional argument *onerror* is specified, it should be a function; it will be called with one argument, an *OSError* instance. It can report the error to continue with the walk, or raise the exception to abort the walk. Note that the filename is available as the `filename` attribute of the exception object.

By default, *walk()* will not walk down into symbolic links that resolve to directories. Set *followlinks* to `True` to visit directories pointed to by symlinks, on systems that support them.

Note: Be aware that setting *followlinks* to `True` can lead to infinite recursion if a link points to a parent directory of itself. *walk()* does not keep track of the directories it visited already.

Note: If you pass a relative pathname, don't change the current working directory between resumptions of *walk()*. *walk()* never changes the current directory, and assumes that its caller doesn't either.

This example displays the number of bytes taken by non-directory files in each directory under the starting directory, except that it doesn't look under any CVS subdirectory:

```
import os
from os.path import join, getsize
for root, dirs, files in os.walk('python/Lib/email'):
    print(root, "consumes", end=" ")
    print(sum(getsize(join(root, name)) for name in files), end=" ")
    print("bytes in", len(files), "non-directory files")
    if 'CVS' in dirs:
        dirs.remove('CVS')  # don't visit CVS directories
```

In the next example (simple implementation of *shutil.rmtree()*), walking the tree bottom-up is essential, *rmdir()* doesn't allow deleting a directory before the directory is empty:

```
# Delete everything reachable from the directory named in "top",
# assuming there are no symbolic links.
```

(continues on next page)

(continued from previous page)

```
# CAUTION:  This is dangerous!  For example, if top == '/', it
# could delete all your disk files.
import os
for root, dirs, files in os.walk(top, topdown=False):
    for name in files:
        os.remove(os.path.join(root, name))
    for name in dirs:
        os.rmdir(os.path.join(root, name))
```

Changed in version 3.5: This function now calls *os.scandir()* instead of *os.listdir()*, making it faster by reducing the number of calls to *os.stat()*.

Changed in version 3.6: Accepts a *path-like object*.

os.fwalk(*top='.'*, *topdown=True*, *onerror=None*, ***, *follow_symlinks=False*, *dir_fd=None*)

This behaves exactly like *walk()*, except that it yields a 4-tuple `(dirpath, dirnames, filenames, dirfd)`, and it supports `dir_fd`.

dirpath, *dirnames* and *filenames* are identical to *walk()* output, and *dirfd* is a file descriptor referring to the directory *dirpath*.

This function always supports *paths relative to directory descriptors* and *not following symlinks*. Note however that, unlike other functions, the *fwalk()* default value for *follow_symlinks* is `False`.

Note: Since *fwalk()* yields file descriptors, those are only valid until the next iteration step, so you should duplicate them (e.g. with *dup()*) if you want to keep them longer.

This example displays the number of bytes taken by non-directory files in each directory under the starting directory, except that it doesn't look under any CVS subdirectory:

```
import os
for root, dirs, files, rootfd in os.fwalk('python/Lib/email'):
    print(root, "consumes", end="")
    print(sum([os.stat(name, dir_fd=rootfd).st_size for name in files]),
          end="")
    print("bytes in", len(files), "non-directory files")
    if 'CVS' in dirs:
        dirs.remove('CVS')  # don't visit CVS directories
```

In the next example, walking the tree bottom-up is essential: *rmdir()* doesn't allow deleting a directory before the directory is empty:

```
# Delete everything reachable from the directory named in "top",
# assuming there are no symbolic links.
# CAUTION:  This is dangerous!  For example, if top == '/', it
# could delete all your disk files.
import os
for root, dirs, files, rootfd in os.fwalk(top, topdown=False):
    for name in files:
        os.unlink(name, dir_fd=rootfd)
    for name in dirs:
        os.rmdir(name, dir_fd=rootfd)
```

Availability: Unix.

New in version 3.3.

Changed in version 3.6: Accepts a *path-like object*.

Changed in version 3.7: Added support for *bytes* paths.

Linux extended attributes

New in version 3.3.

These functions are all available on Linux only.

os.getxattr(*path*, *attribute*, ***, *follow_symlinks=True*)
Return the value of the extended filesystem attribute *attribute* for *path*. *attribute* can be bytes or str (directly or indirectly through the *PathLike* interface). If it is str, it is encoded with the filesystem encoding.

This function can support *specifying a file descriptor* and *not following symlinks*.

Changed in version 3.6: Accepts a *path-like object* for *path* and *attribute*.

os.listxattr(*path=None*, ***, *follow_symlinks=True*)
Return a list of the extended filesystem attributes on *path*. The attributes in the list are represented as strings decoded with the filesystem encoding. If *path* is `None`, *listxattr()* will examine the current directory.

This function can support *specifying a file descriptor* and *not following symlinks*.

Changed in version 3.6: Accepts a *path-like object*.

os.removexattr(*path*, *attribute*, ***, *follow_symlinks=True*)
Removes the extended filesystem attribute *attribute* from *path*. *attribute* should be bytes or str (directly or indirectly through the *PathLike* interface). If it is a string, it is encoded with the filesystem encoding.

This function can support *specifying a file descriptor* and *not following symlinks*.

Changed in version 3.6: Accepts a *path-like object* for *path* and *attribute*.

os.setxattr(*path*, *attribute*, *value*, *flags=0*, ***, *follow_symlinks=True*)
Set the extended filesystem attribute *attribute* on *path* to *value*. *attribute* must be a bytes or str with no embedded NULs (directly or indirectly through the *PathLike* interface). If it is a str, it is encoded with the filesystem encoding. *flags* may be *XATTR_REPLACE* or *XATTR_CREATE*. If *XATTR_REPLACE* is given and the attribute does not exist, `EEXISTS` will be raised. If *XATTR_CREATE* is given and the attribute already exists, the attribute will not be created and `ENODATA` will be raised.

This function can support *specifying a file descriptor* and *not following symlinks*.

Note: A bug in Linux kernel versions less than 2.6.39 caused the flags argument to be ignored on some filesystems.

Changed in version 3.6: Accepts a *path-like object* for *path* and *attribute*.

os.XATTR_SIZE_MAX
The maximum size the value of an extended attribute can be. Currently, this is 64 KiB on Linux.

os.XATTR_CREATE
This is a possible value for the flags argument in *setxattr()*. It indicates the operation must create an attribute.

os.XATTR_REPLACE
This is a possible value for the flags argument in *setxattr()*. It indicates the operation must replace an existing attribute.

16.1.6 Process Management

These functions may be used to create and manage processes.

The various *exec** functions take a list of arguments for the new program loaded into the process. In each case, the first of these arguments is passed to the new program as its own name rather than as an argument a user may have typed on a command line. For the C programmer, this is the `argv[0]` passed to a program's `main()`. For example, `os.execv('/bin/echo', ['foo', 'bar'])` will only print `bar` on standard output; `foo` will seem to be ignored.

`os.abort()`
Generate a `SIGABRT` signal to the current process. On Unix, the default behavior is to produce a core dump; on Windows, the process immediately returns an exit code of `3`. Be aware that calling this function will not call the Python signal handler registered for `SIGABRT` with *signal.signal()*.

`os.execl`(*path*, *arg0*, *arg1*, *...*)
`os.execle`(*path*, *arg0*, *arg1*, *...*, *env*)
`os.execlp`(*file*, *arg0*, *arg1*, *...*)
`os.execlpe`(*file*, *arg0*, *arg1*, *...*, *env*)
`os.execv`(*path*, *args*)
`os.execve`(*path*, *args*, *env*)
`os.execvp`(*file*, *args*)
`os.execvpe`(*file*, *args*, *env*)
These functions all execute a new program, replacing the current process; they do not return. On Unix, the new executable is loaded into the current process, and will have the same process id as the caller. Errors will be reported as *OSError* exceptions.

The current process is replaced immediately. Open file objects and descriptors are not flushed, so if there may be data buffered on these open files, you should flush them using `sys.stdout.flush()` or *os.fsync()* before calling an *exec** function.

The "l" and "v" variants of the *exec** functions differ in how command-line arguments are passed. The "l" variants are perhaps the easiest to work with if the number of parameters is fixed when the code is written; the individual parameters simply become additional parameters to the `execl*()` functions. The "v" variants are good when the number of parameters is variable, with the arguments being passed in a list or tuple as the *args* parameter. In either case, the arguments to the child process should start with the name of the command being run, but this is not enforced.

The variants which include a "p" near the end (*execlp()*, *execlpe()*, *execvp()*, and *execvpe()*) will use the `PATH` environment variable to locate the program *file*. When the environment is being replaced (using one of the *exec*e* variants, discussed in the next paragraph), the new environment is used as the source of the `PATH` variable. The other variants, *execl()*, *execle()*, *execv()*, and *execve()*, will not use the `PATH` variable to locate the executable; *path* must contain an appropriate absolute or relative path.

For *execle()*, *execlpe()*, *execve()*, and *execvpe()* (note that these all end in "e"), the *env* parameter must be a mapping which is used to define the environment variables for the new process (these are used instead of the current process' environment); the functions *execl()*, *execlp()*, *execv()*, and *execvp()* all cause the new process to inherit the environment of the current process.

For *execve()* on some platforms, *path* may also be specified as an open file descriptor. This functionality may not be supported on your platform; you can check whether or not it is available using *os.supports_fd*. If it is unavailable, using it will raise a *NotImplementedError*.

Availability: Unix, Windows.

New in version 3.3: Added support for specifying an open file descriptor for *path* for *execve()*.

Changed in version 3.6: Accepts a *path-like object*.

os._exit(*n*)
Exit the process with status *n*, without calling cleanup handlers, flushing stdio buffers, etc.

Note: The standard way to exit is `sys.exit(n)`. *_exit()* should normally only be used in the child process after a *fork()*.

The following exit codes are defined and can be used with *_exit()*, although they are not required. These are typically used for system programs written in Python, such as a mail server's external command delivery program.

Note: Some of these may not be available on all Unix platforms, since there is some variation. These constants are defined where they are defined by the underlying platform.

os.EX_OK
Exit code that means no error occurred.

Availability: Unix.

os.EX_USAGE
Exit code that means the command was used incorrectly, such as when the wrong number of arguments are given.

Availability: Unix.

os.EX_DATAERR
Exit code that means the input data was incorrect.

Availability: Unix.

os.EX_NOINPUT
Exit code that means an input file did not exist or was not readable.

Availability: Unix.

os.EX_NOUSER
Exit code that means a specified user did not exist.

Availability: Unix.

os.EX_NOHOST
Exit code that means a specified host did not exist.

Availability: Unix.

os.EX_UNAVAILABLE
Exit code that means that a required service is unavailable.

Availability: Unix.

os.EX_SOFTWARE
Exit code that means an internal software error was detected.

Availability: Unix.

os.EX_OSERR
Exit code that means an operating system error was detected, such as the inability to fork or create a pipe.

Availability: Unix.

os.EX_OSFILE
Exit code that means some system file did not exist, could not be opened, or had some other kind of error.

Availability: Unix.

os.EX_CANTCREAT
: Exit code that means a user specified output file could not be created.

  Availability: Unix.

os.EX_IOERR
: Exit code that means that an error occurred while doing I/O on some file.

  Availability: Unix.

os.EX_TEMPFAIL
: Exit code that means a temporary failure occurred. This indicates something that may not really be an error, such as a network connection that couldn't be made during a retryable operation.

  Availability: Unix.

os.EX_PROTOCOL
: Exit code that means that a protocol exchange was illegal, invalid, or not understood.

  Availability: Unix.

os.EX_NOPERM
: Exit code that means that there were insufficient permissions to perform the operation (but not intended for file system problems).

  Availability: Unix.

os.EX_CONFIG
: Exit code that means that some kind of configuration error occurred.

  Availability: Unix.

os.EX_NOTFOUND
: Exit code that means something like "an entry was not found".

  Availability: Unix.

os.fork()
: Fork a child process. Return `0` in the child and the child's process id in the parent. If an error occurs *OSError* is raised.

  Note that some platforms including FreeBSD <= 6.3 and Cygwin have known issues when using fork() from a thread.

  > **Warning:** See *ssl* for applications that use the SSL module with fork().

  Availability: Unix.

os.forkpty()
: Fork a child process, using a new pseudo-terminal as the child's controlling terminal. Return a pair of `(pid, fd)`, where *pid* is `0` in the child, the new child's process id in the parent, and *fd* is the file descriptor of the master end of the pseudo-terminal. For a more portable approach, use the *pty* module. If an error occurs *OSError* is raised.

  Availability: some flavors of Unix.

os.kill(*pid*, *sig*)
: Send signal *sig* to the process *pid*. Constants for the specific signals available on the host platform are defined in the *signal* module.

Windows: The *signal.CTRL_C_EVENT* and *signal.CTRL_BREAK_EVENT* signals are special signals which can only be sent to console processes which share a common console window, e.g., some subprocesses. Any other value for *sig* will cause the process to be unconditionally killed by the TerminateProcess API, and the exit code will be set to *sig*. The Windows version of *kill()* additionally takes process handles to be killed.

See also *signal.pthread_kill()*.

New in version 3.2: Windows support.

`os.killpg`(*pgid*, *sig*)
Send the signal *sig* to the process group *pgid*.

Availability: Unix.

`os.nice`(*increment*)
Add *increment* to the process's "niceness". Return the new niceness.

Availability: Unix.

`os.plock`(*op*)
Lock program segments into memory. The value of *op* (defined in `<sys/lock.h>`) determines which segments are locked.

Availability: Unix.

`os.popen`(*cmd*, *mode='r'*, *buffering=-1*)
Open a pipe to or from command *cmd*. The return value is an open file object connected to the pipe, which can be read or written depending on whether *mode* is `'r'` (default) or `'w'`. The *buffering* argument has the same meaning as the corresponding argument to the built-in *open()* function. The returned file object reads or writes text strings rather than bytes.

The `close` method returns *None* if the subprocess exited successfully, or the subprocess's return code if there was an error. On POSIX systems, if the return code is positive it represents the return value of the process left-shifted by one byte. If the return code is negative, the process was terminated by the signal given by the negated value of the return code. (For example, the return value might be `-signal.SIGKILL` if the subprocess was killed.) On Windows systems, the return value contains the signed integer return code from the child process.

This is implemented using *subprocess.Popen*; see that class's documentation for more powerful ways to manage and communicate with subprocesses.

`os.register_at_fork`(***, *before=None*, *after_in_parent=None*, *after_in_child=None*)
Register callables to be executed when a new child process is forked using *os.fork()* or similar process cloning APIs. The parameters are optional and keyword-only. Each specifies a different call point.

- *before* is a function called before forking a child process.
- *after_in_parent* is a function called from the parent process after forking a child process.
- *after_in_child* is a function called from the child process.

These calls are only made if control is expected to return to the Python interpreter. A typical *subprocess* launch will not trigger them as the child is not going to re-enter the interpreter.

Functions registered for execution before forking are called in reverse registration order. Functions registered for execution after forking (either in the parent or in the child) are called in registration order.

Note that `fork()` calls made by third-party C code may not call those functions, unless it explicitly calls `PyOS_BeforeFork()`, `PyOS_AfterFork_Parent()` and `PyOS_AfterFork_Child()`.

There is no way to unregister a function.

Availability: Unix.

New in version 3.7.

os.**spawnl**(*mode*, *path*, *...*)
os.**spawnle**(*mode*, *path*, *...*, *env*)
os.**spawnlp**(*mode*, *file*, *...*)
os.**spawnlpe**(*mode*, *file*, *...*, *env*)
os.**spawnv**(*mode*, *path*, *args*)
os.**spawnve**(*mode*, *path*, *args*, *env*)
os.**spawnvp**(*mode*, *file*, *args*)
os.**spawnvpe**(*mode*, *file*, *args*, *env*)

Execute the program *path* in a new process.

(Note that the *subprocess* module provides more powerful facilities for spawning new processes and retrieving their results; using that module is preferable to using these functions. Check especially the *Replacing Older Functions with the subprocess Module* section.)

If *mode* is *P_NOWAIT*, this function returns the process id of the new process; if *mode* is *P_WAIT*, returns the process's exit code if it exits normally, or `-signal`, where *signal* is the signal that killed the process. On Windows, the process id will actually be the process handle, so can be used with the *waitpid()* function.

The "l" and "v" variants of the *spawn** functions differ in how command-line arguments are passed. The "l" variants are perhaps the easiest to work with if the number of parameters is fixed when the code is written; the individual parameters simply become additional parameters to the `spawnl*()` functions. The "v" variants are good when the number of parameters is variable, with the arguments being passed in a list or tuple as the *args* parameter. In either case, the arguments to the child process must start with the name of the command being run.

The variants which include a second "p" near the end (*spawnlp()*, *spawnlpe()*, *spawnvp()*, and *spawnvpe()*) will use the `PATH` environment variable to locate the program *file*. When the environment is being replaced (using one of the *spawn*e* variants, discussed in the next paragraph), the new environment is used as the source of the `PATH` variable. The other variants, *spawnl()*, *spawnle()*, *spawnv()*, and *spawnve()*, will not use the `PATH` variable to locate the executable; *path* must contain an appropriate absolute or relative path.

For *spawnle()*, *spawnlpe()*, *spawnve()*, and *spawnvpe()* (note that these all end in "e"), the *env* parameter must be a mapping which is used to define the environment variables for the new process (they are used instead of the current process' environment); the functions *spawnl()*, *spawnlp()*, *spawnv()*, and *spawnvp()* all cause the new process to inherit the environment of the current process. Note that keys and values in the *env* dictionary must be strings; invalid keys or values will cause the function to fail, with a return value of `127`.

As an example, the following calls to *spawnlp()* and *spawnvpe()* are equivalent:

```
import os
os.spawnlp(os.P_WAIT, 'cp', 'cp', 'index.html', '/dev/null')

L = ['cp', 'index.html', '/dev/null']
os.spawnvpe(os.P_WAIT, 'cp', L, os.environ)
```

Availability: Unix, Windows. *spawnlp()*, *spawnlpe()*, *spawnvp()* and *spawnvpe()* are not available on Windows. *spawnle()* and *spawnve()* are not thread-safe on Windows; we advise you to use the *subprocess* module instead.

Changed in version 3.6: Accepts a *path-like object*.

os.**P_NOWAIT**
os.**P_NOWAITO**

Possible values for the *mode* parameter to the *spawn** family of functions. If either of these values is

given, the spawn*() functions will return as soon as the new process has been created, with the process id as the return value.

Availability: Unix, Windows.

os.P_WAIT
Possible value for the *mode* parameter to the *spawn** family of functions. If this is given as *mode*, the spawn*() functions will not return until the new process has run to completion and will return the exit code of the process the run is successful, or -signal if a signal kills the process.

Availability: Unix, Windows.

os.P_DETACH
os.P_OVERLAY
Possible values for the *mode* parameter to the *spawn** family of functions. These are less portable than those listed above. *P_DETACH* is similar to *P_NOWAIT*, but the new process is detached from the console of the calling process. If *P_OVERLAY* is used, the current process will be replaced; the *spawn** function will not return.

Availability: Windows.

os.startfile(*path*[, *operation*])
Start a file with its associated application.

When *operation* is not specified or 'open', this acts like double-clicking the file in Windows Explorer, or giving the file name as an argument to the start command from the interactive command shell: the file is opened with whatever application (if any) its extension is associated.

When another *operation* is given, it must be a "command verb" that specifies what should be done with the file. Common verbs documented by Microsoft are 'print' and 'edit' (to be used on files) as well as 'explore' and 'find' (to be used on directories).

startfile() returns as soon as the associated application is launched. There is no option to wait for the application to close, and no way to retrieve the application's exit status. The *path* parameter is relative to the current directory. If you want to use an absolute path, make sure the first character is not a slash ('/'); the underlying Win32 ShellExecute() function doesn't work if it is. Use the *os.path.normpath()* function to ensure that the path is properly encoded for Win32.

To reduce interpreter startup overhead, the Win32 ShellExecute() function is not resolved until this function is first called. If the function cannot be resolved, *NotImplementedError* will be raised.

Availability: Windows.

os.system(*command*)
Execute the command (a string) in a subshell. This is implemented by calling the Standard C function system(), and has the same limitations. Changes to *sys.stdin*, etc. are not reflected in the environment of the executed command. If *command* generates any output, it will be sent to the interpreter standard output stream.

On Unix, the return value is the exit status of the process encoded in the format specified for *wait()*. Note that POSIX does not specify the meaning of the return value of the C system() function, so the return value of the Python function is system-dependent.

On Windows, the return value is that returned by the system shell after running *command*. The shell is given by the Windows environment variable COMSPEC: it is usually cmd.exe, which returns the exit status of the command run; on systems using a non-native shell, consult your shell documentation.

The *subprocess* module provides more powerful facilities for spawning new processes and retrieving their results; using that module is preferable to using this function. See the *Replacing Older Functions with the subprocess Module* section in the *subprocess* documentation for some helpful recipes.

Availability: Unix, Windows.

os.times()
Returns the current global process times. The return value is an object with five attributes:

- user - user time
- system - system time
- children_user - user time of all child processes
- children_system - system time of all child processes
- elapsed - elapsed real time since a fixed point in the past

For backwards compatibility, this object also behaves like a five-tuple containing user, system, children_user, children_system, and elapsed in that order.

See the Unix manual page *times(2)* or the corresponding Windows Platform API documentation. On Windows, only user and system are known; the other attributes are zero.

Availability: Unix, Windows.

Changed in version 3.3: Return type changed from a tuple to a tuple-like object with named attributes.

os.wait()
Wait for completion of a child process, and return a tuple containing its pid and exit status indication: a 16-bit number, whose low byte is the signal number that killed the process, and whose high byte is the exit status (if the signal number is zero); the high bit of the low byte is set if a core file was produced.

Availability: Unix.

os.waitid(*idtype*, *id*, *options*)
Wait for the completion of one or more child processes. *idtype* can be *P_PID*, *P_PGID* or *P_ALL*. *id* specifies the pid to wait on. *options* is constructed from the ORing of one or more of *WEXITED*, *WSTOPPED* or *WCONTINUED* and additionally may be ORed with *WNOHANG* or *WNOWAIT*. The return value is an object representing the data contained in the siginfo_t structure, namely: si_pid, si_uid, si_signo, si_status, si_code or None if *WNOHANG* is specified and there are no children in a waitable state.

Availability: Unix.

New in version 3.3.

os.P_PID
os.P_PGID
os.P_ALL
These are the possible values for *idtype* in *waitid()*. They affect how *id* is interpreted.

Availability: Unix.

New in version 3.3.

os.WEXITED
os.WSTOPPED
os.WNOWAIT
Flags that can be used in *options* in *waitid()* that specify what child signal to wait for.

Availability: Unix.

New in version 3.3.

os.CLD_EXITED
os.CLD_DUMPED
os.CLD_TRAPPED

os.CLD_CONTINUED
These are the possible values for si_code in the result returned by *waitid()*.

Availability: Unix.

New in version 3.3.

os.waitpid(*pid*, *options*)
The details of this function differ on Unix and Windows.

On Unix: Wait for completion of a child process given by process id *pid*, and return a tuple containing its process id and exit status indication (encoded as for *wait()*). The semantics of the call are affected by the value of the integer *options*, which should be 0 for normal operation.

If *pid* is greater than 0, *waitpid()* requests status information for that specific process. If *pid* is 0, the request is for the status of any child in the process group of the current process. If *pid* is -1, the request pertains to any child of the current process. If *pid* is less than -1, status is requested for any process in the process group -pid (the absolute value of *pid*).

An *OSError* is raised with the value of errno when the syscall returns -1.

On Windows: Wait for completion of a process given by process handle *pid*, and return a tuple containing *pid*, and its exit status shifted left by 8 bits (shifting makes cross-platform use of the function easier). A *pid* less than or equal to 0 has no special meaning on Windows, and raises an exception. The value of integer *options* has no effect. *pid* can refer to any process whose id is known, not necessarily a child process. The *spawn** functions called with *P_NOWAIT* return suitable process handles.

Changed in version 3.5: If the system call is interrupted and the signal handler does not raise an exception, the function now retries the system call instead of raising an *InterruptedError* exception (see **PEP 475** for the rationale).

os.wait3(*options*)
Similar to *waitpid()*, except no process id argument is given and a 3-element tuple containing the child's process id, exit status indication, and resource usage information is returned. Refer to *resource.getrusage()* for details on resource usage information. The option argument is the same as that provided to *waitpid()* and *wait4()*.

Availability: Unix.

os.wait4(*pid*, *options*)
Similar to *waitpid()*, except a 3-element tuple, containing the child's process id, exit status indication, and resource usage information is returned. Refer to *resource.getrusage()* for details on resource usage information. The arguments to *wait4()* are the same as those provided to *waitpid()*.

Availability: Unix.

os.WNOHANG
The option for *waitpid()* to return immediately if no child process status is available immediately. The function returns (0, 0) in this case.

Availability: Unix.

os.WCONTINUED
This option causes child processes to be reported if they have been continued from a job control stop since their status was last reported.

Availability: some Unix systems.

os.WUNTRACED
This option causes child processes to be reported if they have been stopped but their current state has not been reported since they were stopped.

Availability: Unix.

The following functions take a process status code as returned by *system()*, *wait()*, or *waitpid()* as a parameter. They may be used to determine the disposition of a process.

`os.WCOREDUMP`(*status*)
Return `True` if a core dump was generated for the process, otherwise return `False`.

Availability: Unix.

`os.WIFCONTINUED`(*status*)
Return `True` if the process has been continued from a job control stop, otherwise return `False`.

Availability: Unix.

`os.WIFSTOPPED`(*status*)
Return `True` if the process has been stopped, otherwise return `False`.

Availability: Unix.

`os.WIFSIGNALED`(*status*)
Return `True` if the process exited due to a signal, otherwise return `False`.

Availability: Unix.

`os.WIFEXITED`(*status*)
Return `True` if the process exited using the *exit(2)* system call, otherwise return `False`.

Availability: Unix.

`os.WEXITSTATUS`(*status*)
If `WIFEXITED(status)` is true, return the integer parameter to the *exit(2)* system call. Otherwise, the return value is meaningless.

Availability: Unix.

`os.WSTOPSIG`(*status*)
Return the signal which caused the process to stop.

Availability: Unix.

`os.WTERMSIG`(*status*)
Return the signal which caused the process to exit.

Availability: Unix.

16.1.7 Interface to the scheduler

These functions control how a process is allocated CPU time by the operating system. They are only available on some Unix platforms. For more detailed information, consult your Unix manpages.

New in version 3.3.

The following scheduling policies are exposed if they are supported by the operating system.

`os.SCHED_OTHER`
The default scheduling policy.

`os.SCHED_BATCH`
Scheduling policy for CPU-intensive processes that tries to preserve interactivity on the rest of the computer.

`os.SCHED_IDLE`
Scheduling policy for extremely low priority background tasks.

`os.SCHED_SPORADIC`
Scheduling policy for sporadic server programs.

os.**SCHED_FIFO**
A First In First Out scheduling policy.

os.**SCHED_RR**
A round-robin scheduling policy.

os.**SCHED_RESET_ON_FORK**
This flag can be OR'ed with any other scheduling policy. When a process with this flag set forks, its child's scheduling policy and priority are reset to the default.

class os.**sched_param**(*sched_priority*)
This class represents tunable scheduling parameters used in *sched_setparam()*, *sched_setscheduler()*, and *sched_getparam()*. It is immutable.

At the moment, there is only one possible parameter:

sched_priority
The scheduling priority for a scheduling policy.

os.**sched_get_priority_min**(*policy*)
Get the minimum priority value for *policy*. *policy* is one of the scheduling policy constants above.

os.**sched_get_priority_max**(*policy*)
Get the maximum priority value for *policy*. *policy* is one of the scheduling policy constants above.

os.**sched_setscheduler**(*pid*, *policy*, *param*)
Set the scheduling policy for the process with PID *pid*. A *pid* of 0 means the calling process. *policy* is one of the scheduling policy constants above. *param* is a *sched_param* instance.

os.**sched_getscheduler**(*pid*)
Return the scheduling policy for the process with PID *pid*. A *pid* of 0 means the calling process. The result is one of the scheduling policy constants above.

os.**sched_setparam**(*pid*, *param*)
Set a scheduling parameters for the process with PID *pid*. A *pid* of 0 means the calling process. *param* is a *sched_param* instance.

os.**sched_getparam**(*pid*)
Return the scheduling parameters as a *sched_param* instance for the process with PID *pid*. A *pid* of 0 means the calling process.

os.**sched_rr_get_interval**(*pid*)
Return the round-robin quantum in seconds for the process with PID *pid*. A *pid* of 0 means the calling process.

os.**sched_yield**()
Voluntarily relinquish the CPU.

os.**sched_setaffinity**(*pid*, *mask*)
Restrict the process with PID *pid* (or the current process if zero) to a set of CPUs. *mask* is an iterable of integers representing the set of CPUs to which the process should be restricted.

os.**sched_getaffinity**(*pid*)
Return the set of CPUs the process with PID *pid* (or the current process if zero) is restricted to.

16.1.8 Miscellaneous System Information

os.**confstr**(*name*)
Return string-valued system configuration values. *name* specifies the configuration value to retrieve; it may be a string which is the name of a defined system value; these names are specified in a number of standards (POSIX, Unix 95, Unix 98, and others). Some platforms define additional names as well.

The names known to the host operating system are given as the keys of the `confstr_names` dictionary. For configuration variables not included in that mapping, passing an integer for *name* is also accepted.

If the configuration value specified by *name* isn't defined, `None` is returned.

If *name* is a string and is not known, *ValueError* is raised. If a specific value for *name* is not supported by the host system, even if it is included in `confstr_names`, an *OSError* is raised with *errno.EINVAL* for the error number.

Availability: Unix.

`os.confstr_names`
Dictionary mapping names accepted by *confstr()* to the integer values defined for those names by the host operating system. This can be used to determine the set of names known to the system.

Availability: Unix.

`os.cpu_count()`
Return the number of CPUs in the system. Returns `None` if undetermined.

This number is not equivalent to the number of CPUs the current process can use. The number of usable CPUs can be obtained with `len(os.sched_getaffinity(0))`

New in version 3.4.

`os.getloadavg()`
Return the number of processes in the system run queue averaged over the last 1, 5, and 15 minutes or raises *OSError* if the load average was unobtainable.

Availability: Unix.

`os.sysconf(`*name*`)`
Return integer-valued system configuration values. If the configuration value specified by *name* isn't defined, `-1` is returned. The comments regarding the *name* parameter for *confstr()* apply here as well; the dictionary that provides information on the known names is given by `sysconf_names`.

Availability: Unix.

`os.sysconf_names`
Dictionary mapping names accepted by *sysconf()* to the integer values defined for those names by the host operating system. This can be used to determine the set of names known to the system.

Availability: Unix.

The following data values are used to support path manipulation operations. These are defined for all platforms.

Higher-level operations on pathnames are defined in the *os.path* module.

`os.curdir`
The constant string used by the operating system to refer to the current directory. This is `'.'` for Windows and POSIX. Also available via *os.path*.

`os.pardir`
The constant string used by the operating system to refer to the parent directory. This is `'..'` for Windows and POSIX. Also available via *os.path*.

`os.sep`
The character used by the operating system to separate pathname components. This is `'/'` for POSIX and `'\\'` for Windows. Note that knowing this is not sufficient to be able to parse or concatenate pathnames — use *os.path.split()* and *os.path.join()* — but it is occasionally useful. Also available via *os.path*.

`os.altsep`
An alternative character used by the operating system to separate pathname components, or `None` if

only one separator character exists. This is set to `'/'` on Windows systems where `sep` is a backslash. Also available via *os.path*.

os.extsep
The character which separates the base filename from the extension; for example, the `'.'` in `os.py`. Also available via *os.path*.

os.pathsep
The character conventionally used by the operating system to separate search path components (as in `PATH`), such as `':'` for POSIX or `';'` for Windows. Also available via *os.path*.

os.defpath
The default search path used by *exec*p** and *spawn*p** if the environment doesn't have a `'PATH'` key. Also available via *os.path*.

os.linesep
The string used to separate (or, rather, terminate) lines on the current platform. This may be a single character, such as `'\n'` for POSIX, or multiple characters, for example, `'\r\n'` for Windows. Do not use *os.linesep* as a line terminator when writing files opened in text mode (the default); use a single `'\n'` instead, on all platforms.

os.devnull
The file path of the null device. For example: `'/dev/null'` for POSIX, `'nul'` for Windows. Also available via *os.path*.

os.RTLD_LAZY
os.RTLD_NOW
os.RTLD_GLOBAL
os.RTLD_LOCAL
os.RTLD_NODELETE
os.RTLD_NOLOAD
os.RTLD_DEEPBIND
Flags for use with the *setdlopenflags()* and *getdlopenflags()* functions. See the Unix manual page *dlopen(3)* for what the different flags mean.

New in version 3.3.

16.1.9 Random numbers

os.getrandom(*size*, *flags=0*)
Get up to *size* random bytes. The function can return less bytes than requested.

These bytes can be used to seed user-space random number generators or for cryptographic purposes.

`getrandom()` relies on entropy gathered from device drivers and other sources of environmental noise. Unnecessarily reading large quantities of data will have a negative impact on other users of the `/dev/random` and `/dev/urandom` devices.

The flags argument is a bit mask that can contain zero or more of the following values ORed together: *os.GRND_RANDOM* and *GRND_NONBLOCK*.

See also the Linux getrandom() manual page.

Availability: Linux 3.17 and newer.

New in version 3.6.

os.urandom(*size*)
Return a string of *size* random bytes suitable for cryptographic use.

This function returns random bytes from an OS-specific randomness source. The returned data should be unpredictable enough for cryptographic applications, though its exact quality depends on the OS implementation.

On Linux, if the `getrandom()` syscall is available, it is used in blocking mode: block until the system urandom entropy pool is initialized (128 bits of entropy are collected by the kernel). See the **PEP 524** for the rationale. On Linux, the *getrandom()* function can be used to get random bytes in non-blocking mode (using the *GRND_NONBLOCK* flag) or to poll until the system urandom entropy pool is initialized.

On a Unix-like system, random bytes are read from the `/dev/urandom` device. If the `/dev/urandom` device is not available or not readable, the *NotImplementedError* exception is raised.

On Windows, it will use `CryptGenRandom()`.

See also:

The *secrets* module provides higher level functions. For an easy-to-use interface to the random number generator provided by your platform, please see *random.SystemRandom*.

Changed in version 3.6.0: On Linux, `getrandom()` is now used in blocking mode to increase the security.

Changed in version 3.5.2: On Linux, if the `getrandom()` syscall blocks (the urandom entropy pool is not initialized yet), fall back on reading `/dev/urandom`.

Changed in version 3.5: On Linux 3.17 and newer, the `getrandom()` syscall is now used when available. On OpenBSD 5.6 and newer, the C `getentropy()` function is now used. These functions avoid the usage of an internal file descriptor.

`os.GRND_NONBLOCK`
By default, when reading from `/dev/random`, *getrandom()* blocks if no random bytes are available, and when reading from `/dev/urandom`, it blocks if the entropy pool has not yet been initialized.

If the *GRND_NONBLOCK* flag is set, then *getrandom()* does not block in these cases, but instead immediately raises *BlockingIOError*.

New in version 3.6.

`os.GRND_RANDOM`
If this bit is set, then random bytes are drawn from the `/dev/random` pool instead of the `/dev/urandom` pool.

New in version 3.6.

16.2 `io` — Core tools for working with streams

Source code: Lib/io.py

16.2.1 Overview

The *io* module provides Python's main facilities for dealing with various types of I/O. There are three main types of I/O: *text I/O*, *binary I/O* and *raw I/O*. These are generic categories, and various backing stores can be used for each of them. A concrete object belonging to any of these categories is called a *file object*. Other common terms are *stream* and *file-like object*.

Independently of its category, each concrete stream object will also have various capabilities: it can be read-only, write-only, or read-write. It can also allow arbitrary random access (seeking forwards or backwards to any location), or only sequential access (for example in the case of a socket or pipe).

All streams are careful about the type of data you give to them. For example giving a *str* object to the `write()` method of a binary stream will raise a `TypeError`. So will giving a *bytes* object to the `write()` method of a text stream.

Changed in version 3.3: Operations that used to raise *IOError* now raise *OSError*, since *IOError* is now an alias of *OSError*.

Text I/O

Text I/O expects and produces *str* objects. This means that whenever the backing store is natively made of bytes (such as in the case of a file), encoding and decoding of data is made transparently as well as optional translation of platform-specific newline characters.

The easiest way to create a text stream is with *open()*, optionally specifying an encoding:

```
f = open("myfile.txt", "r", encoding="utf-8")
```

In-memory text streams are also available as *StringIO* objects:

```
f = io.StringIO("some initial text data")
```

The text stream API is described in detail in the documentation of *TextIOBase*.

Binary I/O

Binary I/O (also called *buffered I/O*) expects *bytes-like objects* and produces *bytes* objects. No encoding, decoding, or newline translation is performed. This category of streams can be used for all kinds of non-text data, and also when manual control over the handling of text data is desired.

The easiest way to create a binary stream is with *open()* with `'b'` in the mode string:

```
f = open("myfile.jpg", "rb")
```

In-memory binary streams are also available as *BytesIO* objects:

```
f = io.BytesIO(b"some initial binary data: \x00\x01")
```

The binary stream API is described in detail in the docs of *BufferedIOBase*.

Other library modules may provide additional ways to create text or binary streams. See *socket.socket.makefile()* for example.

Raw I/O

Raw I/O (also called *unbuffered I/O*) is generally used as a low-level building-block for binary and text streams; it is rarely useful to directly manipulate a raw stream from user code. Nevertheless, you can create a raw stream by opening a file in binary mode with buffering disabled:

```
f = open("myfile.jpg", "rb", buffering=0)
```

The raw stream API is described in detail in the docs of *RawIOBase*.

16.2.2 High-level Module Interface

`io.DEFAULT_BUFFER_SIZE`
An int containing the default buffer size used by the module's buffered I/O classes. *open()* uses the file's blksize (as obtained by *os.stat()*) if possible.

`io.open`(*file*, *mode='r'*, *buffering=-1*, *encoding=None*, *errors=None*, *newline=None*, *closefd=True*, *opener=None*)
This is an alias for the builtin *open()* function.

`exception io.BlockingIOError`
This is a compatibility alias for the builtin *BlockingIOError* exception.

`exception io.UnsupportedOperation`
An exception inheriting *OSError* and *ValueError* that is raised when an unsupported operation is called on a stream.

In-memory streams

It is also possible to use a *str* or *bytes-like object* as a file for both reading and writing. For strings *StringIO* can be used like a file opened in text mode. *BytesIO* can be used like a file opened in binary mode. Both provide full read-write capabilities with random access.

See also:

sys contains the standard IO streams: *sys.stdin*, *sys.stdout*, and *sys.stderr*.

16.2.3 Class hierarchy

The implementation of I/O streams is organized as a hierarchy of classes. First *abstract base classes* (ABCs), which are used to specify the various categories of streams, then concrete classes providing the standard stream implementations.

Note: The abstract base classes also provide default implementations of some methods in order to help implementation of concrete stream classes. For example, *BufferedIOBase* provides unoptimized implementations of `readinto()` and *readline()*.

At the top of the I/O hierarchy is the abstract base class *IOBase*. It defines the basic interface to a stream. Note, however, that there is no separation between reading and writing to streams; implementations are allowed to raise *UnsupportedOperation* if they do not support a given operation.

The *RawIOBase* ABC extends *IOBase*. It deals with the reading and writing of bytes to a stream. *FileIO* subclasses *RawIOBase* to provide an interface to files in the machine's file system.

The *BufferedIOBase* ABC deals with buffering on a raw byte stream (*RawIOBase*). Its subclasses, *BufferedWriter*, *BufferedReader*, and *BufferedRWPair* buffer streams that are readable, writable, and both readable and writable. *BufferedRandom* provides a buffered interface to random access streams. Another *BufferedIOBase* subclass, *BytesIO*, is a stream of in-memory bytes.

The *TextIOBase* ABC, another subclass of *IOBase*, deals with streams whose bytes represent text, and handles encoding and decoding to and from strings. *TextIOWrapper*, which extends it, is a buffered text interface to a buffered raw stream (*BufferedIOBase*). Finally, *StringIO* is an in-memory stream for text.

Argument names are not part of the specification, and only the arguments of *open()* are intended to be used as keyword arguments.

The following table summarizes the ABCs provided by the *io* module:

ABC	Inherits	Stub Methods	Mixin Methods and Properties
IOBase		`fileno`, `seek`, and `truncate`	`close`, `closed`, `__enter__`, `__exit__`, `flush`, `isatty`, `__iter__`, `__next__`, `readable`, `readline`, `readlines`, `seekable`, `tell`, `writable`, and `writelines`
RawIOBase	*IOBase*	`readinto` and `write`	Inherited *IOBase* methods, `read`, and `readall`
BufferedIOBase	*IOBase*	`detach`, `read`, `read1`, and `write`	Inherited *IOBase* methods, `readinto`, and `readinto1`
TextIOBase	*IOBase*	`detach`, `read`, `readline`, and `write`	Inherited *IOBase* methods, `encoding`, `errors`, and `newlines`

I/O Base Classes

class io.IOBase

The abstract base class for all I/O classes, acting on streams of bytes. There is no public constructor.

This class provides empty abstract implementations for many methods that derived classes can override selectively; the default implementations represent a file that cannot be read, written or seeked.

Even though *IOBase* does not declare `read()`, `readinto()`, or `write()` because their signatures will vary, implementations and clients should consider those methods part of the interface. Also, implementations may raise a *ValueError* (or *UnsupportedOperation*) when operations they do not support are called.

The basic type used for binary data read from or written to a file is *bytes*. Other *bytes-like objects* are accepted as method arguments too. In some cases, such as *readinto()*, a writable object such as *bytearray* is required. Text I/O classes work with *str* data.

Note that calling any method (even inquiries) on a closed stream is undefined. Implementations may raise *ValueError* in this case.

IOBase (and its subclasses) supports the iterator protocol, meaning that an *IOBase* object can be iterated over yielding the lines in a stream. Lines are defined slightly differently depending on whether the stream is a binary stream (yielding bytes), or a text stream (yielding character strings). See *readline()* below.

IOBase is also a context manager and therefore supports the `with` statement. In this example, *file* is closed after the `with` statement's suite is finished—even if an exception occurs:

```
with open('spam.txt', 'w') as file:
    file.write('Spam and eggs!')
```

IOBase provides these data attributes and methods:

close()

Flush and close this stream. This method has no effect if the file is already closed. Once the file is closed, any operation on the file (e.g. reading or writing) will raise a *ValueError*.

As a convenience, it is allowed to call this method more than once; only the first call, however, will have an effect.

closed

`True` if the stream is closed.

fileno()
Return the underlying file descriptor (an integer) of the stream if it exists. An *OSError* is raised if the IO object does not use a file descriptor.

flush()
Flush the write buffers of the stream if applicable. This does nothing for read-only and non-blocking streams.

isatty()
Return `True` if the stream is interactive (i.e., connected to a terminal/tty device).

readable()
Return `True` if the stream can be read from. If `False`, `read()` will raise *OSError*.

readline(*size=-1*)
Read and return one line from the stream. If *size* is specified, at most *size* bytes will be read.

The line terminator is always `b'\n'` for binary files; for text files, the *newline* argument to *open()* can be used to select the line terminator(s) recognized.

readlines(*hint=-1*)
Read and return a list of lines from the stream. *hint* can be specified to control the number of lines read: no more lines will be read if the total size (in bytes/characters) of all lines so far exceeds *hint*.

Note that it's already possible to iterate on file objects using `for line in file: ...` without calling `file.readlines()`.

seek(*offset*[, *whence*])
Change the stream position to the given byte *offset*. *offset* is interpreted relative to the position indicated by *whence*. The default value for *whence* is `SEEK_SET`. Values for *whence* are:

- `SEEK_SET` or `0` – start of the stream (the default); *offset* should be zero or positive
- `SEEK_CUR` or `1` – current stream position; *offset* may be negative
- `SEEK_END` or `2` – end of the stream; *offset* is usually negative

Return the new absolute position.

New in version 3.1: The `SEEK_*` constants.

New in version 3.3: Some operating systems could support additional values, like `os.SEEK_HOLE` or `os.SEEK_DATA`. The valid values for a file could depend on it being open in text or binary mode.

seekable()
Return `True` if the stream supports random access. If `False`, *seek()*, *tell()* and *truncate()* will raise *OSError*.

tell()
Return the current stream position.

truncate(*size=None*)
Resize the stream to the given *size* in bytes (or the current position if *size* is not specified). The current stream position isn't changed. This resizing can extend or reduce the current file size. In case of extension, the contents of the new file area depend on the platform (on most systems, additional bytes are zero-filled). The new file size is returned.

Changed in version 3.5: Windows will now zero-fill files when extending.

writable()
Return `True` if the stream supports writing. If `False`, `write()` and *truncate()* will raise *OSError*.

writelines(*lines*)
Write a list of lines to the stream. Line separators are not added, so it is usual for each of the lines provided to have a line separator at the end.

__del__()
Prepare for object destruction. *IOBase* provides a default implementation of this method that calls the instance's *close()* method.

class io.RawIOBase
Base class for raw binary I/O. It inherits *IOBase*. There is no public constructor.

Raw binary I/O typically provides low-level access to an underlying OS device or API, and does not try to encapsulate it in high-level primitives (this is left to Buffered I/O and Text I/O, described later in this page).

In addition to the attributes and methods from *IOBase*, *RawIOBase* provides the following methods:

read(*size=-1*)
Read up to *size* bytes from the object and return them. As a convenience, if *size* is unspecified or -1, all bytes until EOF are returned. Otherwise, only one system call is ever made. Fewer than *size* bytes may be returned if the operating system call returns fewer than *size* bytes.

If 0 bytes are returned, and *size* was not 0, this indicates end of file. If the object is in non-blocking mode and no bytes are available, `None` is returned.

The default implementation defers to *readall()* and *readinto()*.

readall()
Read and return all the bytes from the stream until EOF, using multiple calls to the stream if necessary.

readinto(*b*)
Read bytes into a pre-allocated, writable *bytes-like object* *b*, and return the number of bytes read. If the object is in non-blocking mode and no bytes are available, `None` is returned.

write(*b*)
Write the given *bytes-like object*, *b*, to the underlying raw stream, and return the number of bytes written. This can be less than the length of *b* in bytes, depending on specifics of the underlying raw stream, and especially if it is in non-blocking mode. `None` is returned if the raw stream is set not to block and no single byte could be readily written to it. The caller may release or mutate *b* after this method returns, so the implementation should only access *b* during the method call.

class io.BufferedIOBase
Base class for binary streams that support some kind of buffering. It inherits *IOBase*. There is no public constructor.

The main difference with *RawIOBase* is that methods *read()*, *readinto()* and *write()* will try (respectively) to read as much input as requested or to consume all given output, at the expense of making perhaps more than one system call.

In addition, those methods can raise *BlockingIOError* if the underlying raw stream is in non-blocking mode and cannot take or give enough data; unlike their *RawIOBase* counterparts, they will never return `None`.

Besides, the *read()* method does not have a default implementation that defers to *readinto()*.

A typical *BufferedIOBase* implementation should not inherit from a *RawIOBase* implementation, but wrap one, like *BufferedWriter* and *BufferedReader* do.

BufferedIOBase provides or overrides these methods and attribute in addition to those from *IOBase*:

raw
The underlying raw stream (a *RawIOBase* instance) that *BufferedIOBase* deals with. This is not part of the *BufferedIOBase* API and may not exist on some implementations.

detach()
Separate the underlying raw stream from the buffer and return it.

After the raw stream has been detached, the buffer is in an unusable state.

Some buffers, like *BytesIO*, do not have the concept of a single raw stream to return from this method. They raise *UnsupportedOperation*.

New in version 3.1.

read(*size=-1*)
Read and return up to *size* bytes. If the argument is omitted, `None`, or negative, data is read and returned until EOF is reached. An empty *bytes* object is returned if the stream is already at EOF.

If the argument is positive, and the underlying raw stream is not interactive, multiple raw reads may be issued to satisfy the byte count (unless EOF is reached first). But for interactive raw streams, at most one raw read will be issued, and a short result does not imply that EOF is imminent.

A *BlockingIOError* is raised if the underlying raw stream is in non blocking-mode, and has no data available at the moment.

read1([*size*])
Read and return up to *size* bytes, with at most one call to the underlying raw stream's *read()* (or *readinto()*) method. This can be useful if you are implementing your own buffering on top of a *BufferedIOBase* object.

If *size* is `-1` (the default), an arbitrary number of bytes are returned (more than zero unless EOF is reached).

readinto(*b*)
Read bytes into a pre-allocated, writable *bytes-like object* *b* and return the number of bytes read.

Like *read()*, multiple reads may be issued to the underlying raw stream, unless the latter is interactive.

A *BlockingIOError* is raised if the underlying raw stream is in non blocking-mode, and has no data available at the moment.

readinto1(*b*)
Read bytes into a pre-allocated, writable *bytes-like object* *b*, using at most one call to the underlying raw stream's *read()* (or *readinto()*) method. Return the number of bytes read.

A *BlockingIOError* is raised if the underlying raw stream is in non blocking-mode, and has no data available at the moment.

New in version 3.5.

write(*b*)
Write the given *bytes-like object*, *b*, and return the number of bytes written (always equal to the length of *b* in bytes, since if the write fails an *OSError* will be raised). Depending on the actual implementation, these bytes may be readily written to the underlying stream, or held in a buffer for performance and latency reasons.

When in non-blocking mode, a *BlockingIOError* is raised if the data needed to be written to the raw stream but it couldn't accept all the data without blocking.

The caller may release or mutate *b* after this method returns, so the implementation should only access *b* during the method call.

Raw File I/O

class io.FileIO(*name*, *mode='r'*, *closefd=True*, *opener=None*)

FileIO represents an OS-level file containing bytes data. It implements the *RawIOBase* interface (and therefore the *IOBase* interface, too).

The *name* can be one of two things:

- a character string or *bytes* object representing the path to the file which will be opened. In this case closefd must be `True` (the default) otherwise an error will be raised.
- an integer representing the number of an existing OS-level file descriptor to which the resulting *FileIO* object will give access. When the FileIO object is closed this fd will be closed as well, unless *closefd* is set to `False`.

The *mode* can be `'r'`, `'w'`, `'x'` or `'a'` for reading (default), writing, exclusive creation or appending. The file will be created if it doesn't exist when opened for writing or appending; it will be truncated when opened for writing. *FileExistsError* will be raised if it already exists when opened for creating. Opening a file for creating implies writing, so this mode behaves in a similar way to `'w'`. Add a `'+'` to the mode to allow simultaneous reading and writing.

The `read()` (when called with a positive argument), `readinto()` and `write()` methods on this class will only make one system call.

A custom opener can be used by passing a callable as *opener*. The underlying file descriptor for the file object is then obtained by calling *opener* with (*name*, *flags*). *opener* must return an open file descriptor (passing *os.open* as *opener* results in functionality similar to passing `None`).

The newly created file is *non-inheritable*.

See the *open()* built-in function for examples on using the *opener* parameter.

Changed in version 3.3: The *opener* parameter was added. The `'x'` mode was added.

Changed in version 3.4: The file is now non-inheritable.

In addition to the attributes and methods from *IOBase* and *RawIOBase*, *FileIO* provides the following data attributes:

mode
The mode as given in the constructor.

name
The file name. This is the file descriptor of the file when no name is given in the constructor.

Buffered Streams

Buffered I/O streams provide a higher-level interface to an I/O device than raw I/O does.

class io.BytesIO(*[initial_bytes]*)

A stream implementation using an in-memory bytes buffer. It inherits *BufferedIOBase*. The buffer is discarded when the *close()* method is called.

The optional argument *initial_bytes* is a *bytes-like object* that contains initial data.

BytesIO provides or overrides these methods in addition to those from *BufferedIOBase* and *IOBase*:

getbuffer()
Return a readable and writable view over the contents of the buffer without copying them. Also, mutating the view will transparently update the contents of the buffer:

```
>>> b = io.BytesIO(b"abcdef")
>>> view = b.getbuffer()
>>> view[2:4] = b"56"
>>> b.getvalue()
b'ab56ef'
```

Note: As long as the view exists, the *BytesIO* object cannot be resized or closed.

New in version 3.2.

getvalue()
Return *bytes* containing the entire contents of the buffer.

read1([*size*])
In *BytesIO*, this is the same as *read()*.

Changed in version 3.7: The *size* argument is now optional.

readinto1(*b*)
In *BytesIO*, this is the same as *readinto()*.

New in version 3.5.

class io.BufferedReader(*raw*, *buffer_size=DEFAULT_BUFFER_SIZE*)
A buffer providing higher-level access to a readable, sequential *RawIOBase* object. It inherits *BufferedIOBase*. When reading data from this object, a larger amount of data may be requested from the underlying raw stream, and kept in an internal buffer. The buffered data can then be returned directly on subsequent reads.

The constructor creates a *BufferedReader* for the given readable *raw* stream and *buffer_size*. If *buffer_size* is omitted, *DEFAULT_BUFFER_SIZE* is used.

BufferedReader provides or overrides these methods in addition to those from *BufferedIOBase* and *IOBase*:

peek([*size*])
Return bytes from the stream without advancing the position. At most one single read on the raw stream is done to satisfy the call. The number of bytes returned may be less or more than requested.

read([*size*])
Read and return *size* bytes, or if *size* is not given or negative, until EOF or if the read call would block in non-blocking mode.

read1([*size*])
Read and return up to *size* bytes with only one call on the raw stream. If at least one byte is buffered, only buffered bytes are returned. Otherwise, one raw stream read call is made.

Changed in version 3.7: The *size* argument is now optional.

class io.BufferedWriter(*raw*, *buffer_size=DEFAULT_BUFFER_SIZE*)
A buffer providing higher-level access to a writeable, sequential *RawIOBase* object. It inherits *BufferedIOBase*. When writing to this object, data is normally placed into an internal buffer. The buffer will be written out to the underlying *RawIOBase* object under various conditions, including:

- when the buffer gets too small for all pending data;
- when *flush()* is called;
- when a **seek()** is requested (for *BufferedRandom* objects);
- when the *BufferedWriter* object is closed or destroyed.

The constructor creates a *BufferedWriter* for the given writeable *raw* stream. If the *buffer_size* is not given, it defaults to *DEFAULT_BUFFER_SIZE*.

BufferedWriter provides or overrides these methods in addition to those from *BufferedIOBase* and *IOBase*:

flush()
Force bytes held in the buffer into the raw stream. A *BlockingIOError* should be raised if the raw stream blocks.

write(*b***)**
Write the *bytes-like object*, *b*, and return the number of bytes written. When in non-blocking mode, a *BlockingIOError* is raised if the buffer needs to be written out but the raw stream blocks.

class io.BufferedRandom(*raw*, *buffer_size=DEFAULT_BUFFER_SIZE***)**
A buffered interface to random access streams. It inherits *BufferedReader* and *BufferedWriter*, and further supports **seek()** and **tell()** functionality.

The constructor creates a reader and writer for a seekable raw stream, given in the first argument. If the *buffer_size* is omitted it defaults to *DEFAULT_BUFFER_SIZE*.

BufferedRandom is capable of anything *BufferedReader* or *BufferedWriter* can do.

class io.BufferedRWPair(*reader*, *writer*, *buffer_size=DEFAULT_BUFFER_SIZE***)**
A buffered I/O object combining two unidirectional *RawIOBase* objects – one readable, the other writeable – into a single bidirectional endpoint. It inherits *BufferedIOBase*.

reader and *writer* are *RawIOBase* objects that are readable and writeable respectively. If the *buffer_size* is omitted it defaults to *DEFAULT_BUFFER_SIZE*.

BufferedRWPair implements all of *BufferedIOBase*'s methods except for *detach()*, which raises *UnsupportedOperation*.

> **Warning:** *BufferedRWPair* does not attempt to synchronize accesses to its underlying raw streams. You should not pass it the same object as reader and writer; use *BufferedRandom* instead.

Text I/O

class io.TextIOBase
Base class for text streams. This class provides a character and line based interface to stream I/O. There is no **readinto()** method because Python's character strings are immutable. It inherits *IOBase*. There is no public constructor.

TextIOBase provides or overrides these data attributes and methods in addition to those from *IOBase*:

encoding
The name of the encoding used to decode the stream's bytes into strings, and to encode strings into bytes.

errors
The error setting of the decoder or encoder.

newlines
A string, a tuple of strings, or **None**, indicating the newlines translated so far. Depending on the implementation and the initial constructor flags, this may not be available.

buffer
The underlying binary buffer (a *BufferedIOBase* instance) that *TextIOBase* deals with. This is not part of the *TextIOBase* API and may not exist in some implementations.

detach()
Separate the underlying binary buffer from the *TextIOBase* and return it.

After the underlying buffer has been detached, the *TextIOBase* is in an unusable state.

Some *TextIOBase* implementations, like *StringIO*, may not have the concept of an underlying buffer and calling this method will raise *UnsupportedOperation*.

New in version 3.1.

read(*size*)
Read and return at most *size* characters from the stream as a single *str*. If *size* is negative or `None`, reads until EOF.

readline(*size=-1*)
Read until newline or EOF and return a single `str`. If the stream is already at EOF, an empty string is returned.

If *size* is specified, at most *size* characters will be read.

seek(*offset*[, *whence*])
Change the stream position to the given *offset*. Behaviour depends on the *whence* parameter. The default value for *whence* is `SEEK_SET`.

- `SEEK_SET` or `0`: seek from the start of the stream (the default); *offset* must either be a number returned by *TextIOBase.tell()*, or zero. Any other *offset* value produces undefined behaviour.
- `SEEK_CUR` or `1`: "seek" to the current position; *offset* must be zero, which is a no-operation (all other values are unsupported).
- `SEEK_END` or `2`: seek to the end of the stream; *offset* must be zero (all other values are unsupported).

Return the new absolute position as an opaque number.

New in version 3.1: The `SEEK_*` constants.

tell()
Return the current stream position as an opaque number. The number does not usually represent a number of bytes in the underlying binary storage.

write(*s*)
Write the string *s* to the stream and return the number of characters written.

class io.TextIOWrapper(*buffer*, *encoding=None*, *errors=None*, *newline=None*, *line_buffering=False*, *write_through=False*)
A buffered text stream over a *BufferedIOBase* binary stream. It inherits *TextIOBase*.

encoding gives the name of the encoding that the stream will be decoded or encoded with. It defaults to *locale.getpreferredencoding(False)*.

errors is an optional string that specifies how encoding and decoding errors are to be handled. Pass `'strict'` to raise a *ValueError* exception if there is an encoding error (the default of `None` has the same effect), or pass `'ignore'` to ignore errors. (Note that ignoring encoding errors can lead to data loss.) `'replace'` causes a replacement marker (such as `'?'`) to be inserted where there is malformed data. `'backslashreplace'` causes malformed data to be replaced by a backslashed escape sequence. When writing, `'xmlcharrefreplace'` (replace with the appropriate XML character reference) or `'namereplace'` (replace with `\N{...}` escape sequences) can be used. Any other error handling name that has been registered with *codecs.register_error()* is also valid.

newline controls how line endings are handled. It can be `None`, `''`, `'\n'`, `'\r'`, and `'\r\n'`. It works as follows:

- When reading input from the stream, if *newline* is `None`, *universal newlines* mode is enabled. Lines in the input can end in `'\n'`, `'\r'`, or `'\r\n'`, and these are translated into `'\n'` before being returned to the caller. If it is `''`, universal newlines mode is enabled, but line endings are returned to the caller untranslated. If it has any of the other legal values, input lines are only terminated by the given string, and the line ending is returned to the caller untranslated.
- When writing output to the stream, if *newline* is `None`, any `'\n'` characters written are translated to the system default line separator, *os.linesep*. If *newline* is `''` or `'\n'`, no translation takes place. If *newline* is any of the other legal values, any `'\n'` characters written are translated to the given string.

If *line_buffering* is `True`, `flush()` is implied when a call to write contains a newline character or a carriage return.

If *write_through* is `True`, calls to `write()` are guaranteed not to be buffered: any data written on the *TextIOWrapper* object is immediately handled to its underlying binary *buffer*.

Changed in version 3.3: The *write_through* argument has been added.

Changed in version 3.3: The default *encoding* is now `locale.getpreferredencoding(False)` instead of `locale.getpreferredencoding()`. Don't change temporary the locale encoding using *locale.setlocale()*, use the current locale encoding instead of the user preferred encoding.

TextIOWrapper provides these members in addition to those of *TextIOBase* and its parents:

line_buffering
Whether line buffering is enabled.

write_through
Whether writes are passed immediately to the underlying binary buffer.

New in version 3.7.

reconfigure(**[, encoding][, errors][, newline][, line_buffering][, write_through]*)
Reconfigure this text stream using new settings for *encoding*, *errors*, *newline*, *line_buffering* and *write_through*.

Parameters not specified keep current settings, except `errors='strict'` is used when *encoding* is specified but *errors* is not specified.

It is not possible to change the encoding or newline if some data has already been read from the stream. On the other hand, changing encoding after write is possible.

This method does an implicit stream flush before setting the new parameters.

New in version 3.7.

class io.StringIO(*initial_value=''*, *newline='\n'*)
An in-memory stream for text I/O. The text buffer is discarded when the *close()* method is called.

The initial value of the buffer can be set by providing *initial_value*. If newline translation is enabled, newlines will be encoded as if by *write()*. The stream is positioned at the start of the buffer.

The *newline* argument works like that of *TextIOWrapper*. The default is to consider only `\n` characters as ends of lines and to do no newline translation. If *newline* is set to `None`, newlines are written as `\n` on all platforms, but universal newline decoding is still performed when reading.

StringIO provides this method in addition to those from *TextIOBase* and its parents:

getvalue()
Return a `str` containing the entire contents of the buffer. Newlines are decoded as if by *read()*, although the stream position is not changed.

Example usage:

```
import io

output = io.StringIO()
output.write('First line.\n')
print('Second line.', file=output)

# Retrieve file contents -- this will be
# 'First line.\nSecond line.\n'
contents = output.getvalue()

# Close object and discard memory buffer --
# .getvalue() will now raise an exception.
output.close()
```

class io.**IncrementalNewlineDecoder**

A helper codec that decodes newlines for *universal newlines* mode. It inherits *codecs.IncrementalDecoder*.

16.2.4 Performance

This section discusses the performance of the provided concrete I/O implementations.

Binary I/O

By reading and writing only large chunks of data even when the user asks for a single byte, buffered I/O hides any inefficiency in calling and executing the operating system's unbuffered I/O routines. The gain depends on the OS and the kind of I/O which is performed. For example, on some modern OSes such as Linux, unbuffered disk I/O can be as fast as buffered I/O. The bottom line, however, is that buffered I/O offers predictable performance regardless of the platform and the backing device. Therefore, it is almost always preferable to use buffered I/O rather than unbuffered I/O for binary data.

Text I/O

Text I/O over a binary storage (such as a file) is significantly slower than binary I/O over the same storage, because it requires conversions between unicode and binary data using a character codec. This can become noticeable handling huge amounts of text data like large log files. Also, `TextIOWrapper.tell()` and `TextIOWrapper.seek()` are both quite slow due to the reconstruction algorithm used.

StringIO, however, is a native in-memory unicode container and will exhibit similar speed to *BytesIO*.

Multi-threading

FileIO objects are thread-safe to the extent that the operating system calls (such as `read(2)` under Unix) they wrap are thread-safe too.

Binary buffered objects (instances of *BufferedReader*, *BufferedWriter*, *BufferedRandom* and *BufferedRWPair*) protect their internal structures using a lock; it is therefore safe to call them from multiple threads at once.

TextIOWrapper objects are not thread-safe.

Reentrancy

Binary buffered objects (instances of *BufferedReader*, *BufferedWriter*, *BufferedRandom* and *BufferedRWPair*) are not reentrant. While reentrant calls will not happen in normal situations, they can arise from doing I/O in a *signal* handler. If a thread tries to re-enter a buffered object which it is already accessing, a *RuntimeError* is raised. Note this doesn't prohibit a different thread from entering the buffered object.

The above implicitly extends to text files, since the *open()* function will wrap a buffered object inside a *TextIOWrapper*. This includes standard streams and therefore affects the built-in function *print()* as well.

16.3 `time` — Time access and conversions

This module provides various time-related functions. For related functionality, see also the *datetime* and *calendar* modules.

Although this module is always available, not all functions are available on all platforms. Most of the functions defined in this module call platform C library functions with the same name. It may sometimes be helpful to consult the platform documentation, because the semantics of these functions varies among platforms.

An explanation of some terminology and conventions is in order.

- The *epoch* is the point where the time starts, and is platform dependent. For Unix, the epoch is January 1, 1970, 00:00:00 (UTC). To find out what the epoch is on a given platform, look at `time.gmtime(0)`.
- The term *seconds since the epoch* refers to the total number of elapsed seconds since the epoch, typically excluding leap seconds. Leap seconds are excluded from this total on all POSIX-compliant platforms.
- The functions in this module may not handle dates and times before the epoch or far in the future. The cut-off point in the future is determined by the C library; for 32-bit systems, it is typically in 2038.
- **Year 2000 (Y2K) issues**: Python depends on the platform's C library, which generally doesn't have year 2000 issues, since all dates and times are represented internally as seconds since the epoch. Function *strptime()* can parse 2-digit years when given `%y` format code. When 2-digit years are parsed, they are converted according to the POSIX and ISO C standards: values 69–99 are mapped to 1969–1999, and values 0–68 are mapped to 2000–2068.
- UTC is Coordinated Universal Time (formerly known as Greenwich Mean Time, or GMT). The acronym UTC is not a mistake but a compromise between English and French.
- DST is Daylight Saving Time, an adjustment of the timezone by (usually) one hour during part of the year. DST rules are magic (determined by local law) and can change from year to year. The C library has a table containing the local rules (often it is read from a system file for flexibility) and is the only source of True Wisdom in this respect.
- The precision of the various real-time functions may be less than suggested by the units in which their value or argument is expressed. E.g. on most Unix systems, the clock "ticks" only 50 or 100 times a second.
- On the other hand, the precision of *time()* and *sleep()* is better than their Unix equivalents: times are expressed as floating point numbers, *time()* returns the most accurate time available (using Unix `gettimeofday()` where available), and *sleep()* will accept a time with a nonzero fraction (Unix `select()` is used to implement this, where available).
- The time value as returned by *gmtime()*, *localtime()*, and *strptime()*, and accepted by *asctime()*, *mktime()* and *strftime()*, is a sequence of 9 integers. The return values of *gmtime()*, *localtime()*, and *strptime()* also offer attribute names for individual fields.

See *struct_time* for a description of these objects.

Changed in version 3.3: The *struct_time* type was extended to provide the `tm_gmtoff` and `tm_zone` attributes when platform supports corresponding `struct tm` members.

Changed in version 3.6: The *struct_time* attributes `tm_gmtoff` and `tm_zone` are now available on all platforms.

- Use the following functions to convert between time representations:

From	To	Use
seconds since the epoch	*struct_time* in UTC	*gmtime()*
seconds since the epoch	*struct_time* in local time	*localtime()*
struct_time in UTC	seconds since the epoch	*calendar.timegm()*
struct_time in local time	seconds since the epoch	*mktime()*

16.3.1 Functions

`time.asctime([t])`
Convert a tuple or *struct_time* representing a time as returned by *gmtime()* or *localtime()* to a string of the following form: `'Sun Jun 20 23:21:05 1993'`. If *t* is not provided, the current time as returned by *localtime()* is used. Locale information is not used by *asctime()*.

Note: Unlike the C function of the same name, *asctime()* does not add a trailing newline.

`time.clock()`
On Unix, return the current processor time as a floating point number expressed in seconds. The precision, and in fact the very definition of the meaning of "processor time", depends on that of the C function of the same name.

On Windows, this function returns wall-clock seconds elapsed since the first call to this function, as a floating point number, based on the Win32 function `QueryPerformanceCounter()`. The resolution is typically better than one microsecond.

Deprecated since version 3.3: The behaviour of this function depends on the platform: use *perf_counter()* or *process_time()* instead, depending on your requirements, to have a well defined behaviour.

`time.pthread_getcpuclockid(`*thread_id*`)`
Return the *clk_id* of the thread-specific CPU-time clock for the specified *thread_id*.

Use *threading.get_ident()* or the *ident* attribute of *threading.Thread* objects to get a suitable value for *thread_id*.

Warning: Passing an invalid or expired *thread_id* may result in undefined behavior, such as segmentation fault.

Availability: Unix (see the man page for *pthread_getcpuclockid(3)* for further information)

New in version 3.7.

`time.clock_getres(`*clk_id*`)`
Return the resolution (precision) of the specified clock *clk_id*. Refer to *Clock ID Constants* for a list of accepted values for *clk_id*.

Availability: Unix.

New in version 3.3.

time.clock_gettime(*clk_id*) → float
Return the time of the specified clock *clk_id*. Refer to *Clock ID Constants* for a list of accepted values for *clk_id*.

Availability: Unix.

New in version 3.3.

time.clock_gettime_ns(*clk_id*) → int
Similar to *clock_gettime()* but return time as nanoseconds.

Availability: Unix.

New in version 3.7.

time.clock_settime(*clk_id*, *time: float*)
Set the time of the specified clock *clk_id*. Currently, *CLOCK_REALTIME* is the only accepted value for *clk_id*.

Availability: Unix.

New in version 3.3.

time.clock_settime_ns(*clk_id*, *time: int*)
Similar to *clock_settime()* but set time with nanoseconds.

Availability: Unix.

New in version 3.7.

time.ctime([*secs*])
Convert a time expressed in seconds since the epoch to a string representing local time. If *secs* is not provided or *None*, the current time as returned by *time()* is used. `ctime(secs)` is equivalent to `asctime(localtime(secs))`. Locale information is not used by *ctime()*.

time.get_clock_info(*name*)
Get information on the specified clock as a namespace object. Supported clock names and the corresponding functions to read their value are:

- `'clock'`: *time.clock()*
- `'monotonic'`: *time.monotonic()*
- `'perf_counter'`: *time.perf_counter()*
- `'process_time'`: *time.process_time()*
- `'thread_time'`: *time.thread_time()*
- `'time'`: *time.time()*

The result has the following attributes:

- *adjustable*: `True` if the clock can be changed automatically (e.g. by a NTP daemon) or manually by the system administrator, `False` otherwise
- *implementation*: The name of the underlying C function used to get the clock value. Refer to *Clock ID Constants* for possible values.
- *monotonic*: `True` if the clock cannot go backward, `False` otherwise
- *resolution*: The resolution of the clock in seconds (*float*)

New in version 3.3.

time.gmtime([*secs*])
Convert a time expressed in seconds since the epoch to a *struct_time* in UTC in which the dst flag is always zero. If *secs* is not provided or *None*, the current time as returned by *time()* is used. Fractions of

a second are ignored. See above for a description of the *struct_time* object. See *calendar.timegm()* for the inverse of this function.

time.localtime([*secs*])
Like *gmtime()* but converts to local time. If *secs* is not provided or *None*, the current time as returned by *time()* is used. The dst flag is set to `1` when DST applies to the given time.

time.mktime(*t*)
This is the inverse function of *localtime()*. Its argument is the *struct_time* or full 9-tuple (since the dst flag is needed; use `-1` as the dst flag if it is unknown) which expresses the time in *local* time, not UTC. It returns a floating point number, for compatibility with *time()*. If the input value cannot be represented as a valid time, either *OverflowError* or *ValueError* will be raised (which depends on whether the invalid value is caught by Python or the underlying C libraries). The earliest date for which it can generate a time is platform-dependent.

time.monotonic() → float
Return the value (in fractional seconds) of a monotonic clock, i.e. a clock that cannot go backwards. The clock is not affected by system clock updates. The reference point of the returned value is undefined, so that only the difference between the results of consecutive calls is valid.

On Windows versions older than Vista, *monotonic()* detects `GetTickCount()` integer overflow (32 bits, roll-over after 49.7 days). It increases an internal epoch (reference time) by 2^{32} each time that an overflow is detected. The epoch is stored in the process-local state and so the value of *monotonic()* may be different in two Python processes running for more than 49 days. On more recent versions of Windows and on other operating systems, *monotonic()* is system-wide.

New in version 3.3.

Changed in version 3.5: The function is now always available.

time.monotonic_ns() → int
Similar to *monotonic()*, but return time as nanoseconds.

New in version 3.7.

time.perf_counter() → float
Return the value (in fractional seconds) of a performance counter, i.e. a clock with the highest available resolution to measure a short duration. It does include time elapsed during sleep and is system-wide. The reference point of the returned value is undefined, so that only the difference between the results of consecutive calls is valid.

New in version 3.3.

time.perf_counter_ns() → int
Similar to *perf_counter()*, but return time as nanoseconds.

New in version 3.7.

time.process_time() → float
Return the value (in fractional seconds) of the sum of the system and user CPU time of the current process. It does not include time elapsed during sleep. It is process-wide by definition. The reference point of the returned value is undefined, so that only the difference between the results of consecutive calls is valid.

New in version 3.3.

time.process_time_ns() → int
Similar to *process_time()* but return time as nanoseconds.

New in version 3.7.

time.sleep(*secs*)
Suspend execution of the calling thread for the given number of seconds. The argument may be a floating point number to indicate a more precise sleep time. The actual suspension time may be less

than that requested because any caught signal will terminate the *sleep()* following execution of that signal's catching routine. Also, the suspension time may be longer than requested by an arbitrary amount because of the scheduling of other activity in the system.

Changed in version 3.5: The function now sleeps at least *secs* even if the sleep is interrupted by a signal, except if the signal handler raises an exception (see **PEP 475** for the rationale).

`time.strftime`(*format*[, *t*])

Convert a tuple or *struct_time* representing a time as returned by *gmtime()* or *localtime()* to a string as specified by the *format* argument. If *t* is not provided, the current time as returned by *localtime()* is used. *format* must be a string. *ValueError* is raised if any field in *t* is outside of the allowed range.

0 is a legal argument for any position in the time tuple; if it is normally illegal the value is forced to a correct one.

The following directives can be embedded in the *format* string. They are shown without the optional field width and precision specification, and are replaced by the indicated characters in the *strftime()* result:

Directive	Meaning	Notes
%a	Locale's abbreviated weekday name.	
%A	Locale's full weekday name.	
%b	Locale's abbreviated month name.	
%B	Locale's full month name.	
%c	Locale's appropriate date and time representation.	
%d	Day of the month as a decimal number [01,31].	
%H	Hour (24-hour clock) as a decimal number [00,23].	
%I	Hour (12-hour clock) as a decimal number [01,12].	
%j	Day of the year as a decimal number [001,366].	
%m	Month as a decimal number [01,12].	
%M	Minute as a decimal number [00,59].	
%p	Locale's equivalent of either AM or PM.	(1)
%S	Second as a decimal number [00,61].	(2)
%U	Week number of the year (Sunday as the first day of the week) as a decimal number [00,53]. All days in a new year preceding the first Sunday are considered to be in week 0.	(3)
%w	Weekday as a decimal number [0(Sunday),6].	
%W	Week number of the year (Monday as the first day of the week) as a decimal number [00,53]. All days in a new year preceding the first Monday are considered to be in week 0.	(3)
%x	Locale's appropriate date representation.	
%X	Locale's appropriate time representation.	
%y	Year without century as a decimal number [00,99].	
%Y	Year with century as a decimal number.	
%z	Time zone offset indicating a positive or negative time difference from UTC/GMT of the form +HHMM or -HHMM, where H represents decimal hour digits and M represents decimal minute digits [-23:59, +23:59].	
%Z	Time zone name (no characters if no time zone exists).	
%%	A literal '%' character.	

Notes:

1. When used with the *strptime()* function, the %p directive only affects the output hour field if the %I directive is used to parse the hour.
2. The range really is 0 to 61; value 60 is valid in timestamps representing leap seconds and value 61 is supported for historical reasons.
3. When used with the *strptime()* function, %U and %W are only used in calculations when the day of the week and the year are specified.

Here is an example, a format for dates compatible with that specified in the **RFC 2822** Internet email standard.[1]

```
>>> from time import gmtime, strftime
>>> strftime("%a, %d %b %Y %H:%M:%S +0000", gmtime())
'Thu, 28 Jun 2001 14:17:15 +0000'
```

Additional directives may be supported on certain platforms, but only the ones listed here have a meaning standardized by ANSI C. To see the full set of format codes supported on your platform, consult the *strftime(3)* documentation.

On some platforms, an optional field width and precision specification can immediately follow the initial '%' of a directive in the following order; this is also not portable. The field width is normally 2 except for %j where it is 3.

time.strptime(*string*[, *format*])

Parse a string representing a time according to a format. The return value is a *struct_time* as returned by *gmtime()* or *localtime()*.

The *format* parameter uses the same directives as those used by *strftime()*; it defaults to "%a %b %d %H:%M:%S %Y" which matches the formatting returned by *ctime()*. If *string* cannot be parsed according to *format*, or if it has excess data after parsing, *ValueError* is raised. The default values used to fill in any missing data when more accurate values cannot be inferred are (1900, 1, 1, 0, 0, 0, 0, 1, -1). Both *string* and *format* must be strings.

For example:

```
>>> import time
>>> time.strptime("30 Nov 00", "%d %b %y")
time.struct_time(tm_year=2000, tm_mon=11, tm_mday=30, tm_hour=0, tm_min=0,
                 tm_sec=0, tm_wday=3, tm_yday=335, tm_isdst=-1)
```

Support for the %Z directive is based on the values contained in tzname and whether daylight is true. Because of this, it is platform-specific except for recognizing UTC and GMT which are always known (and are considered to be non-daylight savings timezones).

Only the directives specified in the documentation are supported. Because strftime() is implemented per platform it can sometimes offer more directives than those listed. But strptime() is independent of any platform and thus does not necessarily support all directives available that are not documented as supported.

class time.struct_time

The type of the time value sequence returned by *gmtime()*, *localtime()*, and *strptime()*. It is an object with a *named tuple* interface: values can be accessed by index and by attribute name. The following values are present:

[1] The use of %Z is now deprecated, but the %z escape that expands to the preferred hour/minute offset is not supported by all ANSI C libraries. Also, a strict reading of the original 1982 **RFC 822** standard calls for a two-digit year (%y rather than %Y), but practice moved to 4-digit years long before the year 2000. After that, **RFC 822** became obsolete and the 4-digit year has been first recommended by **RFC 1123** and then mandated by **RFC 2822**.

Index	Attribute	Values
0	`tm_year`	(for example, 1993)
1	`tm_mon`	range [1, 12]
2	`tm_mday`	range [1, 31]
3	`tm_hour`	range [0, 23]
4	`tm_min`	range [0, 59]
5	`tm_sec`	range [0, 61]; see **(2)** in *strftime()* description
6	`tm_wday`	range [0, 6], Monday is 0
7	`tm_yday`	range [1, 366]
8	`tm_isdst`	0, 1 or -1; see below
N/A	`tm_zone`	abbreviation of timezone name
N/A	`tm_gmtoff`	offset east of UTC in seconds

Note that unlike the C structure, the month value is a range of [1, 12], not [0, 11].

In calls to *mktime()*, `tm_isdst` may be set to 1 when daylight savings time is in effect, and 0 when it is not. A value of -1 indicates that this is not known, and will usually result in the correct state being filled in.

When a tuple with an incorrect length is passed to a function expecting a *struct_time*, or having elements of the wrong type, a *TypeError* is raised.

time.time() → float
Return the time in seconds since the *epoch* as a floating point number. The specific date of the epoch and the handling of leap seconds is platform dependent. On Windows and most Unix systems, the epoch is January 1, 1970, 00:00:00 (UTC) and leap seconds are not counted towards the time in seconds since the epoch. This is commonly referred to as Unix time. To find out what the epoch is on a given platform, look at `gmtime(0)`.

Note that even though the time is always returned as a floating point number, not all systems provide time with a better precision than 1 second. While this function normally returns non-decreasing values, it can return a lower value than a previous call if the system clock has been set back between the two calls.

The number returned by *time()* may be converted into a more common time format (i.e. year, month, day, hour, etc…) in UTC by passing it to *gmtime()* function or in local time by passing it to the *localtime()* function. In both cases a *struct_time* object is returned, from which the components of the calendar date may be accessed as attributes.

time.thread_time() → float
Return the value (in fractional seconds) of the sum of the system and user CPU time of the current thread. It does not include time elapsed during sleep. It is thread-specific by definition. The reference point of the returned value is undefined, so that only the difference between the results of consecutive calls in the same thread is valid.

Availability: Windows, Linux, Unix systems supporting `CLOCK_THREAD_CPUTIME_ID`.

New in version 3.7.

time.thread_time_ns() → int
Similar to *thread_time()* but return time as nanoseconds.

New in version 3.7.

time.time_ns() → int
Similar to *time()* but returns time as an integer number of nanoseconds since the *epoch*.

New in version 3.7.

`time.tzset()`

Reset the time conversion rules used by the library routines. The environment variable `TZ` specifies how this is done. It will also set the variables `tzname` (from the `TZ` environment variable), `timezone` (non-DST seconds West of UTC), `altzone` (DST seconds west of UTC) and `daylight` (to 0 if this timezone does not have any daylight saving time rules, or to nonzero if there is a time, past, present or future when daylight saving time applies).

Availability: Unix.

Note: Although in many cases, changing the `TZ` environment variable may affect the output of functions like *`localtime()`* without calling *`tzset()`*, this behavior should not be relied on.

The `TZ` environment variable should contain no whitespace.

The standard format of the `TZ` environment variable is (whitespace added for clarity):

```
std offset [dst [offset [,start[/time], end[/time]]]]
```

Where the components are:

`std and dst` Three or more alphanumerics giving the timezone abbreviations. These will be propagated into time.tzname

`offset` The offset has the form: ± `hh[:mm[:ss]]`. This indicates the value added the local time to arrive at UTC. If preceded by a '-', the timezone is east of the Prime Meridian; otherwise, it is west. If no offset follows dst, summer time is assumed to be one hour ahead of standard time.

`start[/time], end[/time]` Indicates when to change to and back from DST. The format of the start and end dates are one of the following:

`Jn` The Julian day *n* (1 <= *n* <= 365). Leap days are not counted, so in all years February 28 is day 59 and March 1 is day 60.

`n` The zero-based Julian day (0 <= *n* <= 365). Leap days are counted, and it is possible to refer to February 29.

`Mm.n.d` The *d*'th day (0 <= *d* <= 6) of week *n* of month *m* of the year (1 <= *n* <= 5, 1 <= *m* <= 12, where week 5 means "the last *d* day in month *m*" which may occur in either the fourth or the fifth week). Week 1 is the first week in which the *d*'th day occurs. Day zero is a Sunday.

`time` has the same format as `offset` except that no leading sign ('-' or '+') is allowed. The default, if time is not given, is 02:00:00.

```
>>> os.environ['TZ'] = 'EST+05EDT,M4.1.0,M10.5.0'
>>> time.tzset()
>>> time.strftime('%X %x %Z')
'02:07:36 05/08/03 EDT'
>>> os.environ['TZ'] = 'AEST-10AEDT-11,M10.5.0,M3.5.0'
>>> time.tzset()
>>> time.strftime('%X %x %Z')
'16:08:12 05/08/03 AEST'
```

On many Unix systems (including *BSD, Linux, Solaris, and Darwin), it is more convenient to use the system's zoneinfo (*`tzfile(5)`*) database to specify the timezone rules. To do this, set the `TZ` environment variable to the path of the required timezone datafile, relative to the root of the systems 'zoneinfo' timezone database, usually located at `/usr/share/zoneinfo`. For example, `'US/Eastern'`, `'Australia/Melbourne'`, `'Egypt'` or `'Europe/Amsterdam'`.

```
>>> os.environ['TZ'] = 'US/Eastern'
>>> time.tzset()
>>> time.tzname
('EST', 'EDT')
>>> os.environ['TZ'] = 'Egypt'
>>> time.tzset()
>>> time.tzname
('EET', 'EEST')
```

16.3.2 Clock ID Constants

These constants are used as parameters for *clock_getres()* and *clock_gettime()*.

time.CLOCK_BOOTTIME
Identical to *CLOCK_MONOTONIC*, except it also includes any time that the system is suspended.

This allows applications to get a suspend-aware monotonic clock without having to deal with the complications of *CLOCK_REALTIME*, which may have discontinuities if the time is changed using `settimeofday()` or similar.

Availability: Linux 2.6.39 or later.

New in version 3.7.

time.CLOCK_HIGHRES
The Solaris OS has a `CLOCK_HIGHRES` timer that attempts to use an optimal hardware source, and may give close to nanosecond resolution. `CLOCK_HIGHRES` is the nonadjustable, high-resolution clock.

Availability: Solaris.

New in version 3.3.

time.CLOCK_MONOTONIC
Clock that cannot be set and represents monotonic time since some unspecified starting point.

Availability: Unix.

New in version 3.3.

time.CLOCK_MONOTONIC_RAW
Similar to *CLOCK_MONOTONIC*, but provides access to a raw hardware-based time that is not subject to NTP adjustments.

Availability: Linux 2.6.28 or later.

New in version 3.3.

time.CLOCK_PROCESS_CPUTIME_ID
High-resolution per-process timer from the CPU.

Availability: Unix.

New in version 3.3.

time.CLOCK_PROF
High-resolution per-process timer from the CPU.

Availability: FreeBSD, NetBSD 7 or later, OpenBSD.

New in version 3.7.

time.CLOCK_THREAD_CPUTIME_ID
Thread-specific CPU-time clock.

Availability: Unix.

New in version 3.3.

`time.CLOCK_UPTIME`
Time whose absolute value is the time the system has been running and not suspended, providing accurate uptime measurement, both absolute and interval.

Availability: FreeBSD, OpenBSD 5.5 or later.

New in version 3.7.

The following constant is the only parameter that can be sent to *clock_settime()*.

`time.CLOCK_REALTIME`
System-wide real-time clock. Setting this clock requires appropriate privileges.

Availability: Unix.

New in version 3.3.

16.3.3 Timezone Constants

`time.altzone`
The offset of the local DST timezone, in seconds west of UTC, if one is defined. This is negative if the local DST timezone is east of UTC (as in Western Europe, including the UK). Only use this if `daylight` is nonzero. See note below.

`time.daylight`
Nonzero if a DST timezone is defined. See note below.

`time.timezone`
The offset of the local (non-DST) timezone, in seconds west of UTC (negative in most of Western Europe, positive in the US, zero in the UK). See note below.

`time.tzname`
A tuple of two strings: the first is the name of the local non-DST timezone, the second is the name of the local DST timezone. If no DST timezone is defined, the second string should not be used. See note below.

Note: For the above Timezone constants (*altzone*, *daylight*, *timezone*, and *tzname*), the value is determined by the timezone rules in effect at module load time or the last time *tzset()* is called and may be incorrect for times in the past. It is recommended to use the `tm_gmtoff` and `tm_zone` results from *localtime()* to obtain timezone information.

See also:

Module *datetime* More object-oriented interface to dates and times.

Module *locale* Internationalization services. The locale setting affects the interpretation of many format specifiers in *strftime()* and *strptime()*.

Module *calendar* General calendar-related functions. *timegm()* is the inverse of *gmtime()* from this module.

16.4 `argparse` — Parser for command-line options, arguments and sub-commands

New in version 3.2.

Source code: Lib/argparse.py

Tutorial

This page contains the API reference information. For a more gentle introduction to Python command-line parsing, have a look at the argparse tutorial.

The *argparse* module makes it easy to write user-friendly command-line interfaces. The program defines what arguments it requires, and *argparse* will figure out how to parse those out of *sys.argv*. The *argparse* module also automatically generates help and usage messages and issues errors when users give the program invalid arguments.

16.4.1 Example

The following code is a Python program that takes a list of integers and produces either the sum or the max:

```
import argparse

parser = argparse.ArgumentParser(description='Process some integers.')
parser.add_argument('integers', metavar='N', type=int, nargs='+',
                    help='an integer for the accumulator')
parser.add_argument('--sum', dest='accumulate', action='store_const',
                    const=sum, default=max,
                    help='sum the integers (default: find the max)')

args = parser.parse_args()
print(args.accumulate(args.integers))
```

Assuming the Python code above is saved into a file called `prog.py`, it can be run at the command line and provides useful help messages:

```
$ python prog.py -h
usage: prog.py [-h] [--sum] N [N ...]

Process some integers.

positional arguments:
 N           an integer for the accumulator

optional arguments:
 -h, --help  show this help message and exit
 --sum       sum the integers (default: find the max)
```

When run with the appropriate arguments, it prints either the sum or the max of the command-line integers:

```
$ python prog.py 1 2 3 4
4

$ python prog.py 1 2 3 4 --sum
10
```

If invalid arguments are passed in, it will issue an error:

```
$ python prog.py a b c
usage: prog.py [-h] [--sum] N [N ...]
prog.py: error: argument N: invalid int value: 'a'
```

The following sections walk you through this example.

Creating a parser

The first step in using the *argparse* is creating an *ArgumentParser* object:

```
>>> parser = argparse.ArgumentParser(description='Process some integers.')
```

The *ArgumentParser* object will hold all the information necessary to parse the command line into Python data types.

Adding arguments

Filling an *ArgumentParser* with information about program arguments is done by making calls to the *add_argument()* method. Generally, these calls tell the *ArgumentParser* how to take the strings on the command line and turn them into objects. This information is stored and used when *parse_args()* is called. For example:

```
>>> parser.add_argument('integers', metavar='N', type=int, nargs='+',
...                     help='an integer for the accumulator')
>>> parser.add_argument('--sum', dest='accumulate', action='store_const',
...                     const=sum, default=max,
...                     help='sum the integers (default: find the max)')
```

Later, calling *parse_args()* will return an object with two attributes, `integers` and `accumulate`. The `integers` attribute will be a list of one or more ints, and the `accumulate` attribute will be either the *sum()* function, if `--sum` was specified at the command line, or the *max()* function if it was not.

Parsing arguments

ArgumentParser parses arguments through the *parse_args()* method. This will inspect the command line, convert each argument to the appropriate type and then invoke the appropriate action. In most cases, this means a simple *Namespace* object will be built up from attributes parsed out of the command line:

```
>>> parser.parse_args(['--sum', '7', '-1', '42'])
Namespace(accumulate=<built-in function sum>, integers=[7, -1, 42])
```

In a script, *parse_args()* will typically be called with no arguments, and the *ArgumentParser* will automatically determine the command-line arguments from *sys.argv*.

16.4.2 ArgumentParser objects

class argparse.ArgumentParser(*prog=None*, *usage=None*, *description=None*, *epilog=None*, *parents=[]*, *formatter_class=argparse.HelpFormatter*, *prefix_chars='-'*, *fromfile_prefix_chars=None*, *argument_default=None*, *conflict_handler='error'*, *add_help=True*, *allow_abbrev=True*)

Create a new *ArgumentParser* object. All parameters should be passed as keyword arguments. Each parameter has its own more detailed description below, but in short they are:

- *prog* - The name of the program (default: `sys.argv[0]`)
- *usage* - The string describing the program usage (default: generated from arguments added to parser)

- *description* - Text to display before the argument help (default: none)
- *epilog* - Text to display after the argument help (default: none)
- *parents* - A list of *ArgumentParser* objects whose arguments should also be included
- *formatter_class* - A class for customizing the help output
- *prefix_chars* - The set of characters that prefix optional arguments (default: '-')
- *fromfile_prefix_chars* - The set of characters that prefix files from which additional arguments should be read (default: `None`)
- *argument_default* - The global default value for arguments (default: `None`)
- *conflict_handler* - The strategy for resolving conflicting optionals (usually unnecessary)
- *add_help* - Add a `-h/--help` option to the parser (default: `True`)
- *allow_abbrev* - Allows long options to be abbreviated if the abbreviation is unambiguous. (default: `True`)

Changed in version 3.5: *allow_abbrev* parameter was added.

The following sections describe how each of these are used.

prog

By default, *ArgumentParser* objects use `sys.argv[0]` to determine how to display the name of the program in help messages. This default is almost always desirable because it will make the help messages match how the program was invoked on the command line. For example, consider a file named `myprogram.py` with the following code:

```
import argparse
parser = argparse.ArgumentParser()
parser.add_argument('--foo', help='foo help')
args = parser.parse_args()
```

The help for this program will display `myprogram.py` as the program name (regardless of where the program was invoked from):

```
$ python myprogram.py --help
usage: myprogram.py [-h] [--foo FOO]

optional arguments:
 -h, --help  show this help message and exit
 --foo FOO   foo help
$ cd ..
$ python subdir/myprogram.py --help
usage: myprogram.py [-h] [--foo FOO]

optional arguments:
 -h, --help  show this help message and exit
 --foo FOO   foo help
```

To change this default behavior, another value can be supplied using the `prog=` argument to *ArgumentParser*:

```
>>> parser = argparse.ArgumentParser(prog='myprogram')
>>> parser.print_help()
usage: myprogram [-h]
```

(continues on next page)

(continued from previous page)

```
optional arguments:
 -h, --help  show this help message and exit
```

Note that the program name, whether determined from `sys.argv[0]` or from the `prog=` argument, is available to help messages using the `%(prog)s` format specifier.

```
>>> parser = argparse.ArgumentParser(prog='myprogram')
>>> parser.add_argument('--foo', help='foo of the %(prog)s program')
>>> parser.print_help()
usage: myprogram [-h] [--foo FOO]

optional arguments:
 -h, --help  show this help message and exit
 --foo FOO   foo of the myprogram program
```

usage

By default, *ArgumentParser* calculates the usage message from the arguments it contains:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('--foo', nargs='?', help='foo help')
>>> parser.add_argument('bar', nargs='+', help='bar help')
>>> parser.print_help()
usage: PROG [-h] [--foo [FOO]] bar [bar ...]

positional arguments:
 bar          bar help

optional arguments:
 -h, --help   show this help message and exit
 --foo [FOO]  foo help
```

The default message can be overridden with the `usage=` keyword argument:

```
>>> parser = argparse.ArgumentParser(prog='PROG', usage='%(prog)s [options]')
>>> parser.add_argument('--foo', nargs='?', help='foo help')
>>> parser.add_argument('bar', nargs='+', help='bar help')
>>> parser.print_help()
usage: PROG [options]

positional arguments:
 bar          bar help

optional arguments:
 -h, --help   show this help message and exit
 --foo [FOO]  foo help
```

The `%(prog)s` format specifier is available to fill in the program name in your usage messages.

description

Most calls to the *ArgumentParser* constructor will use the `description=` keyword argument. This argument gives a brief description of what the program does and how it works. In help messages, the description is displayed between the command-line usage string and the help messages for the various arguments:

```
>>> parser = argparse.ArgumentParser(description='A foo that bars')
>>> parser.print_help()
usage: argparse.py [-h]

A foo that bars

optional arguments:
 -h, --help  show this help message and exit
```

By default, the description will be line-wrapped so that it fits within the given space. To change this behavior, see the *formatter_class* argument.

epilog

Some programs like to display additional description of the program after the description of the arguments. Such text can be specified using the `epilog=` argument to *ArgumentParser*:

```
>>> parser = argparse.ArgumentParser(
...     description='A foo that bars',
...     epilog="And that's how you'd foo a bar")
>>> parser.print_help()
usage: argparse.py [-h]

A foo that bars

optional arguments:
 -h, --help  show this help message and exit

And that's how you'd foo a bar
```

As with the *description* argument, the `epilog=` text is by default line-wrapped, but this behavior can be adjusted with the *formatter_class* argument to *ArgumentParser*.

parents

Sometimes, several parsers share a common set of arguments. Rather than repeating the definitions of these arguments, a single parser with all the shared arguments and passed to `parents=` argument to *ArgumentParser* can be used. The `parents=` argument takes a list of *ArgumentParser* objects, collects all the positional and optional actions from them, and adds these actions to the *ArgumentParser* object being constructed:

```
>>> parent_parser = argparse.ArgumentParser(add_help=False)
>>> parent_parser.add_argument('--parent', type=int)

>>> foo_parser = argparse.ArgumentParser(parents=[parent_parser])
>>> foo_parser.add_argument('foo')
>>> foo_parser.parse_args(['--parent', '2', 'XXX'])
Namespace(foo='XXX', parent=2)

>>> bar_parser = argparse.ArgumentParser(parents=[parent_parser])
>>> bar_parser.add_argument('--bar')
>>> bar_parser.parse_args(['--bar', 'YYY'])
Namespace(bar='YYY', parent=None)
```

Note that most parent parsers will specify `add_help=False`. Otherwise, the *ArgumentParser* will see two `-h/--help` options (one in the parent and one in the child) and raise an error.

Note: You must fully initialize the parsers before passing them via `parents=`. If you change the parent parsers after the child parser, those changes will not be reflected in the child.

formatter_class

ArgumentParser objects allow the help formatting to be customized by specifying an alternate formatting class. Currently, there are four such classes:

class argparse.RawDescriptionHelpFormatter
class argparse.RawTextHelpFormatter
class argparse.ArgumentDefaultsHelpFormatter
class argparse.MetavarTypeHelpFormatter

RawDescriptionHelpFormatter and *RawTextHelpFormatter* give more control over how textual descriptions are displayed. By default, *ArgumentParser* objects line-wrap the *description* and *epilog* texts in command-line help messages:

```
>>> parser = argparse.ArgumentParser(
...     prog='PROG',
...     description='''this description
...         was indented weird
...             but that is okay''',
...     epilog='''
...             likewise for this epilog whose whitespace will
...         be cleaned up and whose words will be wrapped
...         across a couple lines''')
>>> parser.print_help()
usage: PROG [-h]

this description was indented weird but that is okay

optional arguments:
 -h, --help  show this help message and exit

likewise for this epilog whose whitespace will be cleaned up and whose words
will be wrapped across a couple lines
```

Passing *RawDescriptionHelpFormatter* as `formatter_class=` indicates that *description* and *epilog* are already correctly formatted and should not be line-wrapped:

```
>>> parser = argparse.ArgumentParser(
...     prog='PROG',
...     formatter_class=argparse.RawDescriptionHelpFormatter,
...     description=textwrap.dedent('''\
...         Please do not mess up this text!
...         --------------------------------
...             I have indented it
...             exactly the way
...             I want it
...         '''))
>>> parser.print_help()
usage: PROG [-h]

Please do not mess up this text!
--------------------------------
```

(continues on next page)

(continued from previous page)

```
   I have indented it
   exactly the way
   I want it

optional arguments:
 -h, --help  show this help message and exit
```

RawTextHelpFormatter maintains whitespace for all sorts of help text, including argument descriptions. However, multiple new lines are replaced with one. If you wish to preserve multiple blank lines, add spaces between the newlines.

ArgumentDefaultsHelpFormatter automatically adds information about default values to each of the argument help messages:

```
>>> parser = argparse.ArgumentParser(
...     prog='PROG',
...     formatter_class=argparse.ArgumentDefaultsHelpFormatter)
>>> parser.add_argument('--foo', type=int, default=42, help='FOO!')
>>> parser.add_argument('bar', nargs='*', default=[1, 2, 3], help='BAR!')
>>> parser.print_help()
usage: PROG [-h] [--foo FOO] [bar [bar ...]]

positional arguments:
 bar         BAR! (default: [1, 2, 3])

optional arguments:
 -h, --help  show this help message and exit
 --foo FOO   FOO! (default: 42)
```

MetavarTypeHelpFormatter uses the name of the *type* argument for each argument as the display name for its values (rather than using the *dest* as the regular formatter does):

```
>>> parser = argparse.ArgumentParser(
...     prog='PROG',
...     formatter_class=argparse.MetavarTypeHelpFormatter)
>>> parser.add_argument('--foo', type=int)
>>> parser.add_argument('bar', type=float)
>>> parser.print_help()
usage: PROG [-h] [--foo int] float

positional arguments:
  float

optional arguments:
  -h, --help  show this help message and exit
  --foo int
```

prefix_chars

Most command-line options will use `-` as the prefix, e.g. `-f/--foo`. Parsers that need to support different or additional prefix characters, e.g. for options like `+f` or `/foo`, may specify them using the `prefix_chars=` argument to the ArgumentParser constructor:

```
>>> parser = argparse.ArgumentParser(prog='PROG', prefix_chars='-+')
>>> parser.add_argument('+f')
```

(continues on next page)

(continued from previous page)

```
>>> parser.add_argument('++bar')
>>> parser.parse_args('+f X ++bar Y'.split())
Namespace(bar='Y', f='X')
```

The `prefix_chars=` argument defaults to `'-'`. Supplying a set of characters that does not include `-` will cause `-f/--foo` options to be disallowed.

fromfile_prefix_chars

Sometimes, for example when dealing with a particularly long argument lists, it may make sense to keep the list of arguments in a file rather than typing it out at the command line. If the `fromfile_prefix_chars=` argument is given to the *ArgumentParser* constructor, then arguments that start with any of the specified characters will be treated as files, and will be replaced by the arguments they contain. For example:

```
>>> with open('args.txt', 'w') as fp:
...     fp.write('-f\nbar')
>>> parser = argparse.ArgumentParser(fromfile_prefix_chars='@')
>>> parser.add_argument('-f')
>>> parser.parse_args(['-f', 'foo', '@args.txt'])
Namespace(f='bar')
```

Arguments read from a file must by default be one per line (but see also *convert_arg_line_to_args()*) and are treated as if they were in the same place as the original file referencing argument on the command line. So in the example above, the expression `['-f', 'foo', '@args.txt']` is considered equivalent to the expression `['-f', 'foo', '-f', 'bar']`.

The `fromfile_prefix_chars=` argument defaults to `None`, meaning that arguments will never be treated as file references.

argument_default

Generally, argument defaults are specified either by passing a default to *add_argument()* or by calling the *set_defaults()* methods with a specific set of name-value pairs. Sometimes however, it may be useful to specify a single parser-wide default for arguments. This can be accomplished by passing the `argument_default=` keyword argument to *ArgumentParser*. For example, to globally suppress attribute creation on *parse_args()* calls, we supply `argument_default=SUPPRESS`:

```
>>> parser = argparse.ArgumentParser(argument_default=argparse.SUPPRESS)
>>> parser.add_argument('--foo')
>>> parser.add_argument('bar', nargs='?')
>>> parser.parse_args(['--foo', '1', 'BAR'])
Namespace(bar='BAR', foo='1')
>>> parser.parse_args([])
Namespace()
```

allow_abbrev

Normally, when you pass an argument list to the *parse_args()* method of an *ArgumentParser*, it *recognizes abbreviations* of long options.

This feature can be disabled by setting `allow_abbrev` to `False`:

```
>>> parser = argparse.ArgumentParser(prog='PROG', allow_abbrev=False)
>>> parser.add_argument('--foobar', action='store_true')
>>> parser.add_argument('--foonley', action='store_false')
>>> parser.parse_args(['--foon'])
usage: PROG [-h] [--foobar] [--foonley]
PROG: error: unrecognized arguments: --foon
```

New in version 3.5.

conflict_handler

ArgumentParser objects do not allow two actions with the same option string. By default, *ArgumentParser* objects raise an exception if an attempt is made to create an argument with an option string that is already in use:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-f', '--foo', help='old foo help')
>>> parser.add_argument('--foo', help='new foo help')
Traceback (most recent call last):
 ..
ArgumentError: argument --foo: conflicting option string(s): --foo
```

Sometimes (e.g. when using *parents*) it may be useful to simply override any older arguments with the same option string. To get this behavior, the value `'resolve'` can be supplied to the `conflict_handler=` argument of *ArgumentParser*:

```
>>> parser = argparse.ArgumentParser(prog='PROG', conflict_handler='resolve')
>>> parser.add_argument('-f', '--foo', help='old foo help')
>>> parser.add_argument('--foo', help='new foo help')
>>> parser.print_help()
usage: PROG [-h] [-f FOO] [--foo FOO]

optional arguments:
 -h, --help  show this help message and exit
 -f FOO      old foo help
 --foo FOO   new foo help
```

Note that *ArgumentParser* objects only remove an action if all of its option strings are overridden. So, in the example above, the old `-f/--foo` action is retained as the `-f` action, because only the `--foo` option string was overridden.

add_help

By default, ArgumentParser objects add an option which simply displays the parser's help message. For example, consider a file named `myprogram.py` containing the following code:

```
import argparse
parser = argparse.ArgumentParser()
parser.add_argument('--foo', help='foo help')
args = parser.parse_args()
```

If `-h` or `--help` is supplied at the command line, the ArgumentParser help will be printed:

```
$ python myprogram.py --help
usage: myprogram.py [-h] [--foo FOO]
```

(continues on next page)

(continued from previous page)

```
optional arguments:
 -h, --help  show this help message and exit
 --foo FOO   foo help
```

Occasionally, it may be useful to disable the addition of this help option. This can be achieved by passing `False` as the `add_help=` argument to *ArgumentParser*:

```
>>> parser = argparse.ArgumentParser(prog='PROG', add_help=False)
>>> parser.add_argument('--foo', help='foo help')
>>> parser.print_help()
usage: PROG [--foo FOO]

optional arguments:
 --foo FOO  foo help
```

The help option is typically `-h/--help`. The exception to this is if the `prefix_chars=` is specified and does not include `-`, in which case `-h` and `--help` are not valid options. In this case, the first character in `prefix_chars` is used to prefix the help options:

```
>>> parser = argparse.ArgumentParser(prog='PROG', prefix_chars='+/')
>>> parser.print_help()
usage: PROG [+h]

optional arguments:
  +h, ++help  show this help message and exit
```

16.4.3 The add_argument() method

`ArgumentParser.add_argument`(*name or flags...*[, *action*][, *nargs*][, *const*][, *default*][, *type*][, *choices*][, *required*][, *help*][, *metavar*][, *dest*])

Define how a single command-line argument should be parsed. Each parameter has its own more detailed description below, but in short they are:

- *name or flags* - Either a name or a list of option strings, e.g. `foo` or `-f, --foo`.
- *action* - The basic type of action to be taken when this argument is encountered at the command line.
- *nargs* - The number of command-line arguments that should be consumed.
- *const* - A constant value required by some *action* and *nargs* selections.
- *default* - The value produced if the argument is absent from the command line.
- *type* - The type to which the command-line argument should be converted.
- *choices* - A container of the allowable values for the argument.
- *required* - Whether or not the command-line option may be omitted (optionals only).
- *help* - A brief description of what the argument does.
- *metavar* - A name for the argument in usage messages.
- *dest* - The name of the attribute to be added to the object returned by *parse_args()*.

The following sections describe how each of these are used.

name or flags

The *add_argument()* method must know whether an optional argument, like `-f` or `--foo`, or a positional argument, like a list of filenames, is expected. The first arguments passed to *add_argument()* must therefore be either a series of flags, or a simple argument name. For example, an optional argument could be created like:

```
>>> parser.add_argument('-f', '--foo')
```

while a positional argument could be created like:

```
>>> parser.add_argument('bar')
```

When *parse_args()* is called, optional arguments will be identified by the `-` prefix, and the remaining arguments will be assumed to be positional:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-f', '--foo')
>>> parser.add_argument('bar')
>>> parser.parse_args(['BAR'])
Namespace(bar='BAR', foo=None)
>>> parser.parse_args(['BAR', '--foo', 'FOO'])
Namespace(bar='BAR', foo='FOO')
>>> parser.parse_args(['--foo', 'FOO'])
usage: PROG [-h] [-f FOO] bar
PROG: error: the following arguments are required: bar
```

action

ArgumentParser objects associate command-line arguments with actions. These actions can do just about anything with the command-line arguments associated with them, though most actions simply add an attribute to the object returned by *parse_args()*. The `action` keyword argument specifies how the command-line arguments should be handled. The supplied actions are:

- `'store'` - This just stores the argument's value. This is the default action. For example:

  ```
  >>> parser = argparse.ArgumentParser()
  >>> parser.add_argument('--foo')
  >>> parser.parse_args('--foo 1'.split())
  Namespace(foo='1')
  ```

- `'store_const'` - This stores the value specified by the *const* keyword argument. The `'store_const'` action is most commonly used with optional arguments that specify some sort of flag. For example:

  ```
  >>> parser = argparse.ArgumentParser()
  >>> parser.add_argument('--foo', action='store_const', const=42)
  >>> parser.parse_args(['--foo'])
  Namespace(foo=42)
  ```

- `'store_true'` and `'store_false'` - These are special cases of `'store_const'` used for storing the values `True` and `False` respectively. In addition, they create default values of `False` and `True` respectively. For example:

  ```
  >>> parser = argparse.ArgumentParser()
  >>> parser.add_argument('--foo', action='store_true')
  >>> parser.add_argument('--bar', action='store_false')
  ```

(continues on next page)

(continued from previous page)

```
>>> parser.add_argument('--baz', action='store_false')
>>> parser.parse_args('--foo --bar'.split())
Namespace(foo=True, bar=False, baz=True)
```

- `'append'` - This stores a list, and appends each argument value to the list. This is useful to allow an option to be specified multiple times. Example usage:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', action='append')
>>> parser.parse_args('--foo 1 --foo 2'.split())
Namespace(foo=['1', '2'])
```

- `'append_const'` - This stores a list, and appends the value specified by the *const* keyword argument to the list. (Note that the *const* keyword argument defaults to `None`.) The `'append_const'` action is typically useful when multiple arguments need to store constants to the same list. For example:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--str', dest='types', action='append_const', const=str)
>>> parser.add_argument('--int', dest='types', action='append_const', const=int)
>>> parser.parse_args('--str --int'.split())
Namespace(types=[<class 'str'>, <class 'int'>])
```

- `'count'` - This counts the number of times a keyword argument occurs. For example, this is useful for increasing verbosity levels:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--verbose', '-v', action='count')
>>> parser.parse_args(['-vvv'])
Namespace(verbose=3)
```

- `'help'` - This prints a complete help message for all the options in the current parser and then exits. By default a help action is automatically added to the parser. See *ArgumentParser* for details of how the output is created.

- `'version'` - This expects a `version=` keyword argument in the *add_argument()* call, and prints version information and exits when invoked:

```
>>> import argparse
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('--version', action='version', version='%(prog)s 2.0')
>>> parser.parse_args(['--version'])
PROG 2.0
```

You may also specify an arbitrary action by passing an Action subclass or other object that implements the same interface. The recommended way to do this is to extend *Action*, overriding the `__call__` method and optionally the `__init__` method.

An example of a custom action:

```
>>> class FooAction(argparse.Action):
...     def __init__(self, option_strings, dest, nargs=None, **kwargs):
...         if nargs is not None:
...             raise ValueError("nargs not allowed")
...         super(FooAction, self).__init__(option_strings, dest, **kwargs)
...     def __call__(self, parser, namespace, values, option_string=None):
...         print('%r %r %r' % (namespace, values, option_string))
...         setattr(namespace, self.dest, values)
```

(continues on next page)

(continued from previous page)

```
...
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', action=FooAction)
>>> parser.add_argument('bar', action=FooAction)
>>> args = parser.parse_args('1 --foo 2'.split())
Namespace(bar=None, foo=None) '1' None
Namespace(bar='1', foo=None) '2' '--foo'
>>> args
Namespace(bar='1', foo='2')
```

For more details, see *Action*.

nargs

ArgumentParser objects usually associate a single command-line argument with a single action to be taken. The `nargs` keyword argument associates a different number of command-line arguments with a single action. The supported values are:

- `N` (an integer). `N` arguments from the command line will be gathered together into a list. For example:

  ```
  >>> parser = argparse.ArgumentParser()
  >>> parser.add_argument('--foo', nargs=2)
  >>> parser.add_argument('bar', nargs=1)
  >>> parser.parse_args('c --foo a b'.split())
  Namespace(bar=['c'], foo=['a', 'b'])
  ```

  Note that `nargs=1` produces a list of one item. This is different from the default, in which the item is produced by itself.

- `'?'`. One argument will be consumed from the command line if possible, and produced as a single item. If no command-line argument is present, the value from *default* will be produced. Note that for optional arguments, there is an additional case - the option string is present but not followed by a command-line argument. In this case the value from *const* will be produced. Some examples to illustrate this:

  ```
  >>> parser = argparse.ArgumentParser()
  >>> parser.add_argument('--foo', nargs='?', const='c', default='d')
  >>> parser.add_argument('bar', nargs='?', default='d')
  >>> parser.parse_args(['XX', '--foo', 'YY'])
  Namespace(bar='XX', foo='YY')
  >>> parser.parse_args(['XX', '--foo'])
  Namespace(bar='XX', foo='c')
  >>> parser.parse_args([])
  Namespace(bar='d', foo='d')
  ```

  One of the more common uses of `nargs='?'` is to allow optional input and output files:

  ```
  >>> parser = argparse.ArgumentParser()
  >>> parser.add_argument('infile', nargs='?', type=argparse.FileType('r'),
  ...                     default=sys.stdin)
  >>> parser.add_argument('outfile', nargs='?', type=argparse.FileType('w'),
  ...                     default=sys.stdout)
  >>> parser.parse_args(['input.txt', 'output.txt'])
  Namespace(infile=<_io.TextIOWrapper name='input.txt' encoding='UTF-8'>,
            outfile=<_io.TextIOWrapper name='output.txt' encoding='UTF-8'>)
  >>> parser.parse_args([])
  ```

(continues on next page)

(continued from previous page)

```
Namespace(infile=<_io.TextIOWrapper name='<stdin>' encoding='UTF-8'>,
          outfile=<_io.TextIOWrapper name='<stdout>' encoding='UTF-8'>)
```

- `'*'`. All command-line arguments present are gathered into a list. Note that it generally doesn't make much sense to have more than one positional argument with `nargs='*'`, but multiple optional arguments with `nargs='*'` is possible. For example:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', nargs='*')
>>> parser.add_argument('--bar', nargs='*')
>>> parser.add_argument('baz', nargs='*')
>>> parser.parse_args('a b --foo x y --bar 1 2'.split())
Namespace(bar=['1', '2'], baz=['a', 'b'], foo=['x', 'y'])
```

- `'+'`. Just like `'*'`, all command-line args present are gathered into a list. Additionally, an error message will be generated if there wasn't at least one command-line argument present. For example:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('foo', nargs='+')
>>> parser.parse_args(['a', 'b'])
Namespace(foo=['a', 'b'])
>>> parser.parse_args([])
usage: PROG [-h] foo [foo ...]
PROG: error: the following arguments are required: foo
```

- `argparse.REMAINDER`. All the remaining command-line arguments are gathered into a list. This is commonly useful for command line utilities that dispatch to other command line utilities:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('--foo')
>>> parser.add_argument('command')
>>> parser.add_argument('args', nargs=argparse.REMAINDER)
>>> print(parser.parse_args('--foo B cmd --arg1 XX ZZ'.split()))
Namespace(args=['--arg1', 'XX', 'ZZ'], command='cmd', foo='B')
```

If the `nargs` keyword argument is not provided, the number of arguments consumed is determined by the *action*. Generally this means a single command-line argument will be consumed and a single item (not a list) will be produced.

const

The `const` argument of *add_argument()* is used to hold constant values that are not read from the command line but are required for the various *ArgumentParser* actions. The two most common uses of it are:

- When *add_argument()* is called with `action='store_const'` or `action='append_const'`. These actions add the `const` value to one of the attributes of the object returned by *parse_args()*. See the *action* description for examples.
- When *add_argument()* is called with option strings (like `-f` or `--foo`) and `nargs='?'`. This creates an optional argument that can be followed by zero or one command-line arguments. When parsing the command line, if the option string is encountered with no command-line argument following it, the value of `const` will be assumed instead. See the *nargs* description for examples.

With the `'store_const'` and `'append_const'` actions, the `const` keyword argument must be given. For other actions, it defaults to `None`.

default

All optional arguments and some positional arguments may be omitted at the command line. The `default` keyword argument of *add_argument()*, whose value defaults to `None`, specifies what value should be used if the command-line argument is not present. For optional arguments, the `default` value is used when the option string was not present at the command line:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', default=42)
>>> parser.parse_args(['--foo', '2'])
Namespace(foo='2')
>>> parser.parse_args([])
Namespace(foo=42)
```

If the `default` value is a string, the parser parses the value as if it were a command-line argument. In particular, the parser applies any *type* conversion argument, if provided, before setting the attribute on the *Namespace* return value. Otherwise, the parser uses the value as is:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--length', default='10', type=int)
>>> parser.add_argument('--width', default=10.5, type=int)
>>> parser.parse_args()
Namespace(length=10, width=10.5)
```

For positional arguments with *nargs* equal to `?` or `*`, the `default` value is used when no command-line argument was present:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('foo', nargs='?', default=42)
>>> parser.parse_args(['a'])
Namespace(foo='a')
>>> parser.parse_args([])
Namespace(foo=42)
```

Providing `default=argparse.SUPPRESS` causes no attribute to be added if the command-line argument was not present:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', default=argparse.SUPPRESS)
>>> parser.parse_args([])
Namespace()
>>> parser.parse_args(['--foo', '1'])
Namespace(foo='1')
```

type

By default, *ArgumentParser* objects read command-line arguments in as simple strings. However, quite often the command-line string should instead be interpreted as another type, like a *float* or *int*. The `type` keyword argument of *add_argument()* allows any necessary type-checking and type conversions to be performed. Common built-in types and functions can be used directly as the value of the `type` argument:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('foo', type=int)
>>> parser.add_argument('bar', type=open)
>>> parser.parse_args('2 temp.txt'.split())
Namespace(bar=<_io.TextIOWrapper name='temp.txt' encoding='UTF-8'>, foo=2)
```

See the section on the *default* keyword argument for information on when the `type` argument is applied to default arguments.

To ease the use of various types of files, the argparse module provides the factory FileType which takes the `mode=`, `bufsize=`, `encoding=` and `errors=` arguments of the *open()* function. For example, `FileType('w')` can be used to create a writable file:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('bar', type=argparse.FileType('w'))
>>> parser.parse_args(['out.txt'])
Namespace(bar=<_io.TextIOWrapper name='out.txt' encoding='UTF-8'>)
```

`type=` can take any callable that takes a single string argument and returns the converted value:

```
>>> def perfect_square(string):
...     value = int(string)
...     sqrt = math.sqrt(value)
...     if sqrt != int(sqrt):
...         msg = "%r is not a perfect square" % string
...         raise argparse.ArgumentTypeError(msg)
...     return value
...
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('foo', type=perfect_square)
>>> parser.parse_args(['9'])
Namespace(foo=9)
>>> parser.parse_args(['7'])
usage: PROG [-h] foo
PROG: error: argument foo: '7' is not a perfect square
```

The *choices* keyword argument may be more convenient for type checkers that simply check against a range of values:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('foo', type=int, choices=range(5, 10))
>>> parser.parse_args(['7'])
Namespace(foo=7)
>>> parser.parse_args(['11'])
usage: PROG [-h] {5,6,7,8,9}
PROG: error: argument foo: invalid choice: 11 (choose from 5, 6, 7, 8, 9)
```

See the *choices* section for more details.

choices

Some command-line arguments should be selected from a restricted set of values. These can be handled by passing a container object as the *choices* keyword argument to *add_argument()*. When the command line is parsed, argument values will be checked, and an error message will be displayed if the argument was not one of the acceptable values:

```
>>> parser = argparse.ArgumentParser(prog='game.py')
>>> parser.add_argument('move', choices=['rock', 'paper', 'scissors'])
>>> parser.parse_args(['rock'])
Namespace(move='rock')
>>> parser.parse_args(['fire'])
usage: game.py [-h] {rock,paper,scissors}
game.py: error: argument move: invalid choice: 'fire' (choose from 'rock',
'paper', 'scissors')
```

Note that inclusion in the *choices* container is checked after any *type* conversions have been performed, so the type of the objects in the *choices* container should match the *type* specified:

```
>>> parser = argparse.ArgumentParser(prog='doors.py')
>>> parser.add_argument('door', type=int, choices=range(1, 4))
>>> print(parser.parse_args(['3']))
Namespace(door=3)
>>> parser.parse_args(['4'])
usage: doors.py [-h] {1,2,3}
doors.py: error: argument door: invalid choice: 4 (choose from 1, 2, 3)
```

Any object that supports the `in` operator can be passed as the *choices* value, so *dict* objects, *set* objects, custom containers, etc. are all supported.

required

In general, the *argparse* module assumes that flags like `-f` and `--bar` indicate *optional* arguments, which can always be omitted at the command line. To make an option *required*, `True` can be specified for the `required=` keyword argument to *add_argument()*:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', required=True)
>>> parser.parse_args(['--foo', 'BAR'])
Namespace(foo='BAR')
>>> parser.parse_args([])
usage: argparse.py [-h] [--foo FOO]
argparse.py: error: option --foo is required
```

As the example shows, if an option is marked as `required`, *parse_args()* will report an error if that option is not present at the command line.

Note: Required options are generally considered bad form because users expect *options* to be *optional*, and thus they should be avoided when possible.

---

help

The `help` value is a string containing a brief description of the argument. When a user requests help (usually by using `-h` or `--help` at the command line), these `help` descriptions will be displayed with each argument:

```
>>> parser = argparse.ArgumentParser(prog='frobble')
>>> parser.add_argument('--foo', action='store_true',
...                     help='foo the bars before frobbling')
>>> parser.add_argument('bar', nargs='+',
...                     help='one of the bars to be frobbled')
>>> parser.parse_args(['-h'])
usage: frobble [-h] [--foo] bar [bar ...]

positional arguments:
 bar     one of the bars to be frobbled

optional arguments:
 -h, --help  show this help message and exit
 --foo   foo the bars before frobbling
```

The help strings can include various format specifiers to avoid repetition of things like the program name or the argument *default*. The available specifiers include the program name, %(prog)s and most keyword arguments to *add_argument()*, e.g. %(default)s, %(type)s, etc.:

```
>>> parser = argparse.ArgumentParser(prog='frobble')
>>> parser.add_argument('bar', nargs='?', type=int, default=42,
...                     help='the bar to %(prog)s (default: %(default)s)')
>>> parser.print_help()
usage: frobble [-h] [bar]

positional arguments:
 bar     the bar to frobble (default: 42)

optional arguments:
 -h, --help  show this help message and exit
```

As the help string supports %-formatting, if you want a literal % to appear in the help string, you must escape it as %%.

argparse supports silencing the help entry for certain options, by setting the help value to argparse.SUPPRESS:

```
>>> parser = argparse.ArgumentParser(prog='frobble')
>>> parser.add_argument('--foo', help=argparse.SUPPRESS)
>>> parser.print_help()
usage: frobble [-h]

optional arguments:
  -h, --help  show this help message and exit
```

metavar

When *ArgumentParser* generates help messages, it needs some way to refer to each expected argument. By default, ArgumentParser objects use the *dest* value as the "name" of each object. By default, for positional argument actions, the *dest* value is used directly, and for optional argument actions, the *dest* value is uppercased. So, a single positional argument with dest='bar' will be referred to as bar. A single optional argument --foo that should be followed by a single command-line argument will be referred to as FOO. An example:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo')
>>> parser.add_argument('bar')
>>> parser.parse_args('X --foo Y'.split())
Namespace(bar='X', foo='Y')
>>> parser.print_help()
usage:  [-h] [--foo FOO] bar

positional arguments:
 bar

optional arguments:
 -h, --help  show this help message and exit
 --foo FOO
```

An alternative name can be specified with metavar:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', metavar='YYY')
>>> parser.add_argument('bar', metavar='XXX')
>>> parser.parse_args('X --foo Y'.split())
Namespace(bar='X', foo='Y')
>>> parser.print_help()
usage:  [-h] [--foo YYY] XXX

positional arguments:
 XXX

optional arguments:
 -h, --help  show this help message and exit
 --foo YYY
```

Note that `metavar` only changes the *displayed* name - the name of the attribute on the *parse_args()* object is still determined by the *dest* value.

Different values of `nargs` may cause the metavar to be used multiple times. Providing a tuple to `metavar` specifies a different display for each of the arguments:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-x', nargs=2)
>>> parser.add_argument('--foo', nargs=2, metavar=('bar', 'baz'))
>>> parser.print_help()
usage: PROG [-h] [-x X X] [--foo bar baz]

optional arguments:
 -h, --help     show this help message and exit
 -x X X
 --foo bar baz
```

dest

Most *ArgumentParser* actions add some value as an attribute of the object returned by *parse_args()*. The name of this attribute is determined by the `dest` keyword argument of *add_argument()*. For positional argument actions, `dest` is normally supplied as the first argument to *add_argument()*:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('bar')
>>> parser.parse_args(['XXX'])
Namespace(bar='XXX')
```

For optional argument actions, the value of `dest` is normally inferred from the option strings. *ArgumentParser* generates the value of `dest` by taking the first long option string and stripping away the initial `--` string. If no long option strings were supplied, `dest` will be derived from the first short option string by stripping the initial `-` character. Any internal `-` characters will be converted to `_` characters to make sure the string is a valid attribute name. The examples below illustrate this behavior:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('-f', '--foo-bar', '--foo')
>>> parser.add_argument('-x', '-y')
>>> parser.parse_args('-f 1 -x 2'.split())
Namespace(foo_bar='1', x='2')
>>> parser.parse_args('--foo 1 -y 2'.split())
Namespace(foo_bar='1', x='2')
```

dest allows a custom attribute name to be provided:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', dest='bar')
>>> parser.parse_args('--foo XXX'.split())
Namespace(bar='XXX')
```

Action classes

Action classes implement the Action API, a callable which returns a callable which processes arguments from the command-line. Any object which follows this API may be passed as the action parameter to add_argument().

class argparse.Action(*option_strings*, *dest*, *nargs=None*, *const=None*, *default=None*, *type=None*, *choices=None*, *required=False*, *help=None*, *metavar=None*)

Action objects are used by an ArgumentParser to represent the information needed to parse a single argument from one or more strings from the command line. The Action class must accept the two positional arguments plus any keyword arguments passed to *ArgumentParser.add_argument()* except for the action itself.

Instances of Action (or return value of any callable to the action parameter) should have attributes "dest", "option_strings", "default", "type", "required", "help", etc. defined. The easiest way to ensure these attributes are defined is to call Action.__init__.

Action instances should be callable, so subclasses must override the __call__ method, which should accept four parameters:

- parser - The ArgumentParser object which contains this action.
- namespace - The *Namespace* object that will be returned by *parse_args()*. Most actions add an attribute to this object using *setattr()*.
- values - The associated command-line arguments, with any type conversions applied. Type conversions are specified with the *type* keyword argument to *add_argument()*.
- option_string - The option string that was used to invoke this action. The option_string argument is optional, and will be absent if the action is associated with a positional argument.

The __call__ method may perform arbitrary actions, but will typically set attributes on the namespace based on dest and values.

16.4.4 The parse_args() method

ArgumentParser.parse_args(*args=None*, *namespace=None*)

Convert argument strings to objects and assign them as attributes of the namespace. Return the populated namespace.

Previous calls to *add_argument()* determine exactly what objects are created and how they are assigned. See the documentation for *add_argument()* for details.

- *args* - List of strings to parse. The default is taken from *sys.argv*.
- *namespace* - An object to take the attributes. The default is a new empty *Namespace* object.

Option value syntax

The *parse_args()* method supports several ways of specifying the value of an option (if it takes one). In the simplest case, the option and its value are passed as two separate arguments:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-x')
>>> parser.add_argument('--foo')
>>> parser.parse_args(['-x', 'X'])
Namespace(foo=None, x='X')
>>> parser.parse_args(['--foo', 'FOO'])
Namespace(foo='FOO', x=None)
```

For long options (options with names longer than a single character), the option and value can also be passed as a single command-line argument, using = to separate them:

```
>>> parser.parse_args(['--foo=FOO'])
Namespace(foo='FOO', x=None)
```

For short options (options only one character long), the option and its value can be concatenated:

```
>>> parser.parse_args(['-xX'])
Namespace(foo=None, x='X')
```

Several short options can be joined together, using only a single - prefix, as long as only the last option (or none of them) requires a value:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-x', action='store_true')
>>> parser.add_argument('-y', action='store_true')
>>> parser.add_argument('-z')
>>> parser.parse_args(['-xyzZ'])
Namespace(x=True, y=True, z='Z')
```

Invalid arguments

While parsing the command line, *parse_args()* checks for a variety of errors, including ambiguous options, invalid types, invalid options, wrong number of positional arguments, etc. When it encounters such an error, it exits and prints the error along with a usage message:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('--foo', type=int)
>>> parser.add_argument('bar', nargs='?')

>>> # invalid type
>>> parser.parse_args(['--foo', 'spam'])
usage: PROG [-h] [--foo FOO] [bar]
PROG: error: argument --foo: invalid int value: 'spam'

>>> # invalid option
>>> parser.parse_args(['--bar'])
usage: PROG [-h] [--foo FOO] [bar]
PROG: error: no such option: --bar

>>> # wrong number of arguments
>>> parser.parse_args(['spam', 'badger'])
usage: PROG [-h] [--foo FOO] [bar]
PROG: error: extra arguments found: badger
```

Arguments containing -

The *parse_args()* method attempts to give errors whenever the user has clearly made a mistake, but some situations are inherently ambiguous. For example, the command-line argument `-1` could either be an attempt to specify an option or an attempt to provide a positional argument. The *parse_args()* method is cautious here: positional arguments may only begin with `-` if they look like negative numbers and there are no options in the parser that look like negative numbers:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-x')
>>> parser.add_argument('foo', nargs='?')

>>> # no negative number options, so -1 is a positional argument
>>> parser.parse_args(['-x', '-1'])
Namespace(foo=None, x='-1')

>>> # no negative number options, so -1 and -5 are positional arguments
>>> parser.parse_args(['-x', '-1', '-5'])
Namespace(foo='-5', x='-1')

>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-1', dest='one')
>>> parser.add_argument('foo', nargs='?')

>>> # negative number options present, so -1 is an option
>>> parser.parse_args(['-1', 'X'])
Namespace(foo=None, one='X')

>>> # negative number options present, so -2 is an option
>>> parser.parse_args(['-2'])
usage: PROG [-h] [-1 ONE] [foo]
PROG: error: no such option: -2

>>> # negative number options present, so both -1s are options
>>> parser.parse_args(['-1', '-1'])
usage: PROG [-h] [-1 ONE] [foo]
PROG: error: argument -1: expected one argument
```

If you have positional arguments that must begin with `-` and don't look like negative numbers, you can insert the pseudo-argument `'--'` which tells *parse_args()* that everything after that is a positional argument:

```
>>> parser.parse_args(['--', '-f'])
Namespace(foo='-f', one=None)
```

Argument abbreviations (prefix matching)

The *parse_args()* method *by default* allows long options to be abbreviated to a prefix, if the abbreviation is unambiguous (the prefix matches a unique option):

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('-bacon')
>>> parser.add_argument('-badger')
>>> parser.parse_args('-bac MMM'.split())
Namespace(bacon='MMM', badger=None)
>>> parser.parse_args('-bad WOOD'.split())
Namespace(bacon=None, badger='WOOD')
```

(continues on next page)

(continued from previous page)

```
>>> parser.parse_args('-ba BA'.split())
usage: PROG [-h] [-bacon BACON] [-badger BADGER]
PROG: error: ambiguous option: -ba could match -badger, -bacon
```

An error is produced for arguments that could produce more than one options. This feature can be disabled by setting *allow_abbrev* to `False`.

Beyond `sys.argv`

Sometimes it may be useful to have an ArgumentParser parse arguments other than those of *sys.argv*. This can be accomplished by passing a list of strings to *parse_args()*. This is useful for testing at the interactive prompt:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument(
...     'integers', metavar='int', type=int, choices=range(10),
...     nargs='+', help='an integer in the range 0..9')
>>> parser.add_argument(
...     '--sum', dest='accumulate', action='store_const', const=sum,
...     default=max, help='sum the integers (default: find the max)')
>>> parser.parse_args(['1', '2', '3', '4'])
Namespace(accumulate=<built-in function max>, integers=[1, 2, 3, 4])
>>> parser.parse_args(['1', '2', '3', '4', '--sum'])
Namespace(accumulate=<built-in function sum>, integers=[1, 2, 3, 4])
```

The Namespace object

class argparse.**Namespace**

Simple class used by default by *parse_args()* to create an object holding attributes and return it.

This class is deliberately simple, just an *object* subclass with a readable string representation. If you prefer to have dict-like view of the attributes, you can use the standard Python idiom, *vars()*:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo')
>>> args = parser.parse_args(['--foo', 'BAR'])
>>> vars(args)
{'foo': 'BAR'}
```

It may also be useful to have an *ArgumentParser* assign attributes to an already existing object, rather than a new *Namespace* object. This can be achieved by specifying the `namespace=` keyword argument:

```
>>> class C:
...     pass
...
>>> c = C()
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo')
>>> parser.parse_args(args=['--foo', 'BAR'], namespace=c)
>>> c.foo
'BAR'
```

16.4.5 Other utilities

Sub-commands

ArgumentParser.**add_subparsers**([*title*][, *description*][, *prog*][, *parser_class*][, *action*][, *option_string*][, *dest*][, *required] [help*][, *metavar*])

Many programs split up their functionality into a number of sub-commands, for example, the `svn` program can invoke sub-commands like `svn checkout`, `svn update`, and `svn commit`. Splitting up functionality this way can be a particularly good idea when a program performs several different functions which require different kinds of command-line arguments. *ArgumentParser* supports the creation of such sub-commands with the *add_subparsers()* method. The *add_subparsers()* method is normally called with no arguments and returns a special action object. This object has a single method, `add_parser()`, which takes a command name and any *ArgumentParser* constructor arguments, and returns an *ArgumentParser* object that can be modified as usual.

Description of parameters:

- title - title for the sub-parser group in help output; by default "subcommands" if description is provided, otherwise uses title for positional arguments
- description - description for the sub-parser group in help output, by default `None`
- prog - usage information that will be displayed with sub-command help, by default the name of the program and any positional arguments before the subparser argument
- parser_class - class which will be used to create sub-parser instances, by default the class of the current parser (e.g. ArgumentParser)
- *action* - the basic type of action to be taken when this argument is encountered at the command line
- *dest* - name of the attribute under which sub-command name will be stored; by default `None` and no value is stored
- *required* - Whether or not a subcommand must be provided, by default `False`.
- *help* - help for sub-parser group in help output, by default `None`
- *metavar* - string presenting available sub-commands in help; by default it is `None` and presents sub-commands in form {cmd1, cmd2, ..}

Some example usage:

```
>>> # create the top-level parser
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> parser.add_argument('--foo', action='store_true', help='foo help')
>>> subparsers = parser.add_subparsers(help='sub-command help')
>>>
>>> # create the parser for the "a" command
>>> parser_a = subparsers.add_parser('a', help='a help')
>>> parser_a.add_argument('bar', type=int, help='bar help')
>>>
>>> # create the parser for the "b" command
>>> parser_b = subparsers.add_parser('b', help='b help')
>>> parser_b.add_argument('--baz', choices='XYZ', help='baz help')
>>>
>>> # parse some argument lists
>>> parser.parse_args(['a', '12'])
Namespace(bar=12, foo=False)
>>> parser.parse_args(['--foo', 'b', '--baz', 'Z'])
Namespace(baz='Z', foo=True)
```

Note that the object returned by *parse_args()* will only contain attributes for the main parser and the subparser that was selected by the command line (and not any other subparsers). So in the example above, when the `a` command is specified, only the `foo` and `bar` attributes are present, and when the `b` command is specified, only the `foo` and `baz` attributes are present.

Similarly, when a help message is requested from a subparser, only the help for that particular parser will be printed. The help message will not include parent parser or sibling parser messages. (A help message for each subparser command, however, can be given by supplying the `help=` argument to `add_parser()` as above.)

```
>>> parser.parse_args(['--help'])
usage: PROG [-h] [--foo] {a,b} ...

positional arguments:
  {a,b}   sub-command help
    a     a help
    b     b help

optional arguments:
  -h, --help  show this help message and exit
  --foo   foo help

>>> parser.parse_args(['a', '--help'])
usage: PROG a [-h] bar

positional arguments:
  bar     bar help

optional arguments:
  -h, --help  show this help message and exit

>>> parser.parse_args(['b', '--help'])
usage: PROG b [-h] [--baz {X,Y,Z}]

optional arguments:
  -h, --help     show this help message and exit
  --baz {X,Y,Z}  baz help
```

The *add_subparsers()* method also supports `title` and `description` keyword arguments. When either is present, the subparser's commands will appear in their own group in the help output. For example:

```
>>> parser = argparse.ArgumentParser()
>>> subparsers = parser.add_subparsers(title='subcommands',
...                                    description='valid subcommands',
...                                    help='additional help')
>>> subparsers.add_parser('foo')
>>> subparsers.add_parser('bar')
>>> parser.parse_args(['-h'])
usage:  [-h] {foo,bar} ...

optional arguments:
  -h, --help  show this help message and exit

subcommands:
  valid subcommands

  {foo,bar}   additional help
```

Furthermore, `add_parser` supports an additional `aliases` argument, which allows multiple strings to refer to the same subparser. This example, like `svn`, aliases `co` as a shorthand for `checkout`:

```
>>> parser = argparse.ArgumentParser()
>>> subparsers = parser.add_subparsers()
>>> checkout = subparsers.add_parser('checkout', aliases=['co'])
>>> checkout.add_argument('foo')
>>> parser.parse_args(['co', 'bar'])
Namespace(foo='bar')
```

One particularly effective way of handling sub-commands is to combine the use of the *add_subparsers()* method with calls to *set_defaults()* so that each subparser knows which Python function it should execute. For example:

```
>>> # sub-command functions
>>> def foo(args):
...     print(args.x * args.y)
...
>>> def bar(args):
...     print('((%s))' % args.z)
...
>>> # create the top-level parser
>>> parser = argparse.ArgumentParser()
>>> subparsers = parser.add_subparsers()
>>>
>>> # create the parser for the "foo" command
>>> parser_foo = subparsers.add_parser('foo')
>>> parser_foo.add_argument('-x', type=int, default=1)
>>> parser_foo.add_argument('y', type=float)
>>> parser_foo.set_defaults(func=foo)
>>>
>>> # create the parser for the "bar" command
>>> parser_bar = subparsers.add_parser('bar')
>>> parser_bar.add_argument('z')
>>> parser_bar.set_defaults(func=bar)
>>>
>>> # parse the args and call whatever function was selected
>>> args = parser.parse_args('foo 1 -x 2'.split())
>>> args.func(args)
2.0
>>>
>>> # parse the args and call whatever function was selected
>>> args = parser.parse_args('bar XYZYX'.split())
>>> args.func(args)
((XYZYX))
```

This way, you can let *parse_args()* do the job of calling the appropriate function after argument parsing is complete. Associating functions with actions like this is typically the easiest way to handle the different actions for each of your subparsers. However, if it is necessary to check the name of the subparser that was invoked, the `dest` keyword argument to the *add_subparsers()* call will work:

```
>>> parser = argparse.ArgumentParser()
>>> subparsers = parser.add_subparsers(dest='subparser_name')
>>> subparser1 = subparsers.add_parser('1')
>>> subparser1.add_argument('-x')
>>> subparser2 = subparsers.add_parser('2')
>>> subparser2.add_argument('y')
>>> parser.parse_args(['2', 'frobble'])
```

(continues on next page)

(continued from previous page)

```
Namespace(subparser_name='2', y='frobble')
```

FileType objects

class argparse.FileType(*mode='r'*, *bufsize=-1*, *encoding=None*, *errors=None*)

The *FileType* factory creates objects that can be passed to the type argument of *ArgumentParser.add_argument()*. Arguments that have *FileType* objects as their type will open command-line arguments as files with the requested modes, buffer sizes, encodings and error handling (see the *open()* function for more details):

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--raw', type=argparse.FileType('wb', 0))
>>> parser.add_argument('out', type=argparse.FileType('w', encoding='UTF-8'))
>>> parser.parse_args(['--raw', 'raw.dat', 'file.txt'])
Namespace(out=<_io.TextIOWrapper name='file.txt' mode='w' encoding='UTF-8'>, raw=<_io.FileIO␣
↪name='raw.dat' mode='wb'>)
```

FileType objects understand the pseudo-argument `'-'` and automatically convert this into `sys.stdin` for readable *FileType* objects and `sys.stdout` for writable *FileType* objects:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('infile', type=argparse.FileType('r'))
>>> parser.parse_args(['-'])
Namespace(infile=<_io.TextIOWrapper name='<stdin>' encoding='UTF-8'>)
```

New in version 3.4: The *encodings* and *errors* keyword arguments.

Argument groups

ArgumentParser.add_argument_group(*title=None*, *description=None*)

By default, *ArgumentParser* groups command-line arguments into "positional arguments" and "optional arguments" when displaying help messages. When there is a better conceptual grouping of arguments than this default one, appropriate groups can be created using the *add_argument_group()* method:

```
>>> parser = argparse.ArgumentParser(prog='PROG', add_help=False)
>>> group = parser.add_argument_group('group')
>>> group.add_argument('--foo', help='foo help')
>>> group.add_argument('bar', help='bar help')
>>> parser.print_help()
usage: PROG [--foo FOO] bar

group:
  bar    bar help
  --foo FOO  foo help
```

The *add_argument_group()* method returns an argument group object which has an *add_argument()* method just like a regular *ArgumentParser*. When an argument is added to the group, the parser treats it just like a normal argument, but displays the argument in a separate group for help messages. The *add_argument_group()* method accepts *title* and *description* arguments which can be used to customize this display:

```
>>> parser = argparse.ArgumentParser(prog='PROG', add_help=False)
>>> group1 = parser.add_argument_group('group1', 'group1 description')
>>> group1.add_argument('foo', help='foo help')
>>> group2 = parser.add_argument_group('group2', 'group2 description')
>>> group2.add_argument('--bar', help='bar help')
>>> parser.print_help()
usage: PROG [--bar BAR] foo

group1:
  group1 description

  foo    foo help

group2:
  group2 description

  --bar BAR  bar help
```

Note that any arguments not in your user-defined groups will end up back in the usual "positional arguments" and "optional arguments" sections.

Mutual exclusion

`ArgumentParser.add_mutually_exclusive_group`(*required=False*)

Create a mutually exclusive group. *argparse* will make sure that only one of the arguments in the mutually exclusive group was present on the command line:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> group = parser.add_mutually_exclusive_group()
>>> group.add_argument('--foo', action='store_true')
>>> group.add_argument('--bar', action='store_false')
>>> parser.parse_args(['--foo'])
Namespace(bar=True, foo=True)
>>> parser.parse_args(['--bar'])
Namespace(bar=False, foo=False)
>>> parser.parse_args(['--foo', '--bar'])
usage: PROG [-h] [--foo | --bar]
PROG: error: argument --bar: not allowed with argument --foo
```

The *add_mutually_exclusive_group()* method also accepts a *required* argument, to indicate that at least one of the mutually exclusive arguments is required:

```
>>> parser = argparse.ArgumentParser(prog='PROG')
>>> group = parser.add_mutually_exclusive_group(required=True)
>>> group.add_argument('--foo', action='store_true')
>>> group.add_argument('--bar', action='store_false')
>>> parser.parse_args([])
usage: PROG [-h] (--foo | --bar)
PROG: error: one of the arguments --foo --bar is required
```

Note that currently mutually exclusive argument groups do not support the *title* and *description* arguments of *add_argument_group()*.

Parser defaults

ArgumentParser.set_defaults(***kwargs*)

Most of the time, the attributes of the object returned by *parse_args()* will be fully determined by inspecting the command-line arguments and the argument actions. *set_defaults()* allows some additional attributes that are determined without any inspection of the command line to be added:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('foo', type=int)
>>> parser.set_defaults(bar=42, baz='badger')
>>> parser.parse_args(['736'])
Namespace(bar=42, baz='badger', foo=736)
```

Note that parser-level defaults always override argument-level defaults:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', default='bar')
>>> parser.set_defaults(foo='spam')
>>> parser.parse_args([])
Namespace(foo='spam')
```

Parser-level defaults can be particularly useful when working with multiple parsers. See the *add_subparsers()* method for an example of this type.

ArgumentParser.get_default(*dest*)

Get the default value for a namespace attribute, as set by either *add_argument()* or by *set_defaults()*:

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', default='badger')
>>> parser.get_default('foo')
'badger'
```

Printing help

In most typical applications, *parse_args()* will take care of formatting and printing any usage or error messages. However, several formatting methods are available:

ArgumentParser.print_usage(*file=None*)

Print a brief description of how the *ArgumentParser* should be invoked on the command line. If *file* is `None`, *sys.stdout* is assumed.

ArgumentParser.print_help(*file=None*)

Print a help message, including the program usage and information about the arguments registered with the *ArgumentParser*. If *file* is `None`, *sys.stdout* is assumed.

There are also variants of these methods that simply return a string instead of printing it:

ArgumentParser.format_usage()

Return a string containing a brief description of how the *ArgumentParser* should be invoked on the command line.

ArgumentParser.format_help()

Return a string containing a help message, including the program usage and information about the arguments registered with the *ArgumentParser*.

Partial parsing

ArgumentParser.**parse_known_args**(*args=None*, *namespace=None*)

Sometimes a script may only parse a few of the command-line arguments, passing the remaining arguments on to another script or program. In these cases, the *parse_known_args()* method can be useful. It works much like *parse_args()* except that it does not produce an error when extra arguments are present. Instead, it returns a two item tuple containing the populated namespace and the list of remaining argument strings.

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo', action='store_true')
>>> parser.add_argument('bar')
>>> parser.parse_known_args(['--foo', '--badger', 'BAR', 'spam'])
(Namespace(bar='BAR', foo=True), ['--badger', 'spam'])
```

Warning: *Prefix matching* rules apply to `parse_known_args()`. The parser may consume an option even if it's just a prefix of one of its known options, instead of leaving it in the remaining arguments list.

Customizing file parsing

ArgumentParser.**convert_arg_line_to_args**(*arg_line*)

Arguments that are read from a file (see the *fromfile_prefix_chars* keyword argument to the *ArgumentParser* constructor) are read one argument per line. *convert_arg_line_to_args()* can be overridden for fancier reading.

This method takes a single argument *arg_line* which is a string read from the argument file. It returns a list of arguments parsed from this string. The method is called once per line read from the argument file, in order.

A useful override of this method is one that treats each space-separated word as an argument. The following example demonstrates how to do this:

```
class MyArgumentParser(argparse.ArgumentParser):
    def convert_arg_line_to_args(self, arg_line):
        return arg_line.split()
```

Exiting methods

ArgumentParser.**exit**(*status=0*, *message=None*)

This method terminates the program, exiting with the specified *status* and, if given, it prints a *message* before that.

ArgumentParser.**error**(*message*)

This method prints a usage message including the *message* to the standard error and terminates the program with a status code of 2.

Intermixed parsing

ArgumentParser.**parse_intermixed_args**(*args=None*, *namespace=None*)

ArgumentParser.**parse_known_intermixed_args**(*args=None*, *namespace=None*)

A number of Unix commands allow the user to intermix optional arguments with positional arguments. The *parse_intermixed_args()* and *parse_known_intermixed_args()* methods support this parsing style.

These parsers do not support all the argparse features, and will raise exceptions if unsupported features are used. In particular, subparsers, `argparse.REMAINDER`, and mutually exclusive groups that include both optionals and positionals are not supported.

The following example shows the difference between *parse_known_args()* and *parse_intermixed_args()*: the former returns `['2', '3']` as unparsed arguments, while the latter collects all the positionals into `rest`.

```
>>> parser = argparse.ArgumentParser()
>>> parser.add_argument('--foo')
>>> parser.add_argument('cmd')
>>> parser.add_argument('rest', nargs='*', type=int)
>>> parser.parse_known_args('doit 1 --foo bar 2 3'.split())
(Namespace(cmd='doit', foo='bar', rest=[1]), ['2', '3'])
>>> parser.parse_intermixed_args('doit 1 --foo bar 2 3'.split())
Namespace(cmd='doit', foo='bar', rest=[1, 2, 3])
```

parse_known_intermixed_args() returns a two item tuple containing the populated namespace and the list of remaining argument strings. *parse_intermixed_args()* raises an error if there are any remaining unparsed argument strings.

New in version 3.7.

16.4.6 Upgrading optparse code

Originally, the *argparse* module had attempted to maintain compatibility with *optparse*. However, *optparse* was difficult to extend transparently, particularly with the changes required to support the new `nargs=` specifiers and better usage messages. When most everything in *optparse* had either been copy-pasted over or monkey-patched, it no longer seemed practical to try to maintain the backwards compatibility.

The *argparse* module improves on the standard library *optparse* module in a number of ways including:

- Handling positional arguments.
- Supporting sub-commands.
- Allowing alternative option prefixes like `+` and `/`.
- Handling zero-or-more and one-or-more style arguments.
- Producing more informative usage messages.
- Providing a much simpler interface for custom `type` and `action`.

A partial upgrade path from *optparse* to *argparse*:

- Replace all *optparse.OptionParser.add_option()* calls with *ArgumentParser.add_argument()* calls.
- Replace `(options, args) = parser.parse_args()` with `args = parser.parse_args()` and add additional *ArgumentParser.add_argument()* calls for the positional arguments. Keep in mind that what was previously called `options`, now in the *argparse* context is called `args`.
- Replace *optparse.OptionParser.disable_interspersed_args()* by using *parse_intermixed_args()* instead of *parse_args()*.
- Replace callback actions and the `callback_*` keyword arguments with `type` or `action` arguments.
- Replace string names for `type` keyword arguments with the corresponding type objects (e.g. int, float, complex, etc).
- Replace `optparse.Values` with *Namespace* and `optparse.OptionError` and `optparse.OptionValueError` with `ArgumentError`.

- Replace strings with implicit arguments such as `%default` or `%prog` with the standard Python syntax to use dictionaries to format strings, that is, `%(default)s` and `%(prog)s`.
- Replace the OptionParser constructor `version` argument with a call to `parser.add_argument('--version', action='version', version='<the version>')`.

16.5 getopt — C-style parser for command line options

Source code: Lib/getopt.py

Note: The *getopt* module is a parser for command line options whose API is designed to be familiar to users of the C `getopt()` function. Users who are unfamiliar with the C `getopt()` function or who would like to write less code and get better help and error messages should consider using the *argparse* module instead.

This module helps scripts to parse the command line arguments in `sys.argv`. It supports the same conventions as the Unix `getopt()` function (including the special meanings of arguments of the form '`-`' and '`--`'). Long options similar to those supported by GNU software may be used as well via an optional third argument.

This module provides two functions and an exception:

`getopt.getopt(`*args*, *shortopts*, *longopts=[]*`)`

Parses command line options and parameter list. *args* is the argument list to be parsed, without the leading reference to the running program. Typically, this means `sys.argv[1:]`. *shortopts* is the string of option letters that the script wants to recognize, with options that require an argument followed by a colon (`':'`; i.e., the same format that Unix `getopt()` uses).

Note: Unlike GNU `getopt()`, after a non-option argument, all further arguments are considered also non-options. This is similar to the way non-GNU Unix systems work.

---

longopts, if specified, must be a list of strings with the names of the long options which should be supported. The leading `'--'` characters should not be included in the option name. Long options which require an argument should be followed by an equal sign (`'='`). Optional arguments are not supported. To accept only long options, *shortopts* should be an empty string. Long options on the command line can be recognized so long as they provide a prefix of the option name that matches exactly one of the accepted options. For example, if *longopts* is `['foo', 'frob']`, the option `--fo` will match as `--foo`, but `--f` will not match uniquely, so *GetoptError* will be raised.

The return value consists of two elements: the first is a list of `(option, value)` pairs; the second is the list of program arguments left after the option list was stripped (this is a trailing slice of *args*). Each option-and-value pair returned has the option as its first element, prefixed with a hyphen for short options (e.g., `'-x'`) or two hyphens for long options (e.g., `'--long-option'`), and the option argument as its second element, or an empty string if the option has no argument. The options occur in the list in the same order in which they were found, thus allowing multiple occurrences. Long and short options may be mixed.

`getopt.gnu_getopt(`*args*, *shortopts*, *longopts=[]*`)`

This function works like *getopt()*, except that GNU style scanning mode is used by default. This means that option and non-option arguments may be intermixed. The *getopt()* function stops processing options as soon as a non-option argument is encountered.

If the first character of the option string is `'+'`, or if the environment variable `POSIXLY_CORRECT` is set, then option processing stops as soon as a non-option argument is encountered.

exception getopt.GetoptError

This is raised when an unrecognized option is found in the argument list or when an option requiring an argument is given none. The argument to the exception is a string indicating the cause of the error. For long options, an argument given to an option which does not require one will also cause this exception to be raised. The attributes `msg` and `opt` give the error message and related option; if there is no specific option to which the exception relates, `opt` is an empty string.

exception getopt.error

Alias for *GetoptError*; for backward compatibility.

An example using only Unix style options:

```
>>> import getopt
>>> args = '-a -b -cfoo -d bar a1 a2'.split()
>>> args
['-a', '-b', '-cfoo', '-d', 'bar', 'a1', 'a2']
>>> optlist, args = getopt.getopt(args, 'abc:d:')
>>> optlist
[('-a', ''), ('-b', ''), ('-c', 'foo'), ('-d', 'bar')]
>>> args
['a1', 'a2']
```

Using long option names is equally easy:

```
>>> s = '--condition=foo --testing --output-file abc.def -x a1 a2'
>>> args = s.split()
>>> args
['--condition=foo', '--testing', '--output-file', 'abc.def', '-x', 'a1', 'a2']
>>> optlist, args = getopt.getopt(args, 'x', [
...     'condition=', 'output-file=', 'testing'])
>>> optlist
[('--condition', 'foo'), ('--testing', ''), ('--output-file', 'abc.def'), ('-x', '')]
>>> args
['a1', 'a2']
```

In a script, typical usage is something like this:

```
import getopt, sys

def main():
    try:
        opts, args = getopt.getopt(sys.argv[1:], "ho:v", ["help", "output="])
    except getopt.GetoptError as err:
        # print help information and exit:
        print(err)  # will print something like "option -a not recognized"
        usage()
        sys.exit(2)
    output = None
    verbose = False
    for o, a in opts:
        if o == "-v":
            verbose = True
        elif o in ("-h", "--help"):
            usage()
            sys.exit()
        elif o in ("-o", "--output"):
```

(continues on next page)

(continued from previous page)

```
            output = a
        else:
            assert False, "unhandled option"
    # ...

if __name__ == "__main__":
    main()
```

Note that an equivalent command line interface could be produced with less code and more informative help and error messages by using the *argparse* module:

```
import argparse

if __name__ == '__main__':
    parser = argparse.ArgumentParser()
    parser.add_argument('-o', '--output')
    parser.add_argument('-v', dest='verbose', action='store_true')
    args = parser.parse_args()
    # ... do something with args.output ...
    # ... do something with args.verbose ..
```

Module *argparse* Alternative command line option and argument parsing library.

16.6 `logging` — Logging facility for Python

Source code: Lib/logging/__init__.py

Important

This page contains the API reference information. For tutorial information and discussion of more advanced topics, see

- Basic Tutorial
- Advanced Tutorial
- Logging Cookbook

This module defines functions and classes which implement a flexible event logging system for applications and libraries.

The key benefit of having the logging API provided by a standard library module is that all Python modules can participate in logging, so your application log can include your own messages integrated with messages from third-party modules.

The module provides a lot of functionality and flexibility. If you are unfamiliar with logging, the best way to get to grips with it is to see the tutorials (see the links on the right).

The basic classes defined by the module, together with their functions, are listed below.

- Loggers expose the interface that application code directly uses.
- Handlers send the log records (created by loggers) to the appropriate destination.

- Filters provide a finer grained facility for determining which log records to output.
- Formatters specify the layout of log records in the final output.

16.6.1 Logger Objects

Loggers have the following attributes and methods. Note that Loggers are never instantiated directly, but always through the module-level function `logging.getLogger(name)`. Multiple calls to *getLogger()* with the same name will always return a reference to the same Logger object.

The `name` is potentially a period-separated hierarchical value, like `foo.bar.baz` (though it could also be just plain `foo`, for example). Loggers that are further down in the hierarchical list are children of loggers higher up in the list. For example, given a logger with a name of `foo`, loggers with names of `foo.bar`, `foo.bar.baz`, and `foo.bam` are all descendants of `foo`. The logger name hierarchy is analogous to the Python package hierarchy, and identical to it if you organise your loggers on a per-module basis using the recommended construction `logging.getLogger(__name__)`. That's because in a module, `__name__` is the module's name in the Python package namespace.

class logging.**Logger**

propagate
If this attribute evaluates to true, events logged to this logger will be passed to the handlers of higher level (ancestor) loggers, in addition to any handlers attached to this logger. Messages are passed directly to the ancestor loggers' handlers - neither the level nor filters of the ancestor loggers in question are considered.

If this evaluates to false, logging messages are not passed to the handlers of ancestor loggers.

The constructor sets this attribute to `True`.

Note: If you attach a handler to a logger *and* one or more of its ancestors, it may emit the same record multiple times. In general, you should not need to attach a handler to more than one logger - if you just attach it to the appropriate logger which is highest in the logger hierarchy, then it will see all events logged by all descendant loggers, provided that their propagate setting is left set to `True`. A common scenario is to attach handlers only to the root logger, and to let propagation take care of the rest.

---

setLevel(*level*)
Sets the threshold for this logger to *level*. Logging messages which are less severe than *level* will be ignored; logging messages which have severity *level* or higher will be emitted by whichever handler or handlers service this logger, unless a handler's level has been set to a higher severity level than *level*.

When a logger is created, the level is set to `NOTSET` (which causes all messages to be processed when the logger is the root logger, or delegation to the parent when the logger is a non-root logger). Note that the root logger is created with level `WARNING`.

The term 'delegation to the parent' means that if a logger has a level of NOTSET, its chain of ancestor loggers is traversed until either an ancestor with a level other than NOTSET is found, or the root is reached.

If an ancestor is found with a level other than NOTSET, then that ancestor's level is treated as the effective level of the logger where the ancestor search began, and is used to determine how a logging event is handled.

If the root is reached, and it has a level of NOTSET, then all messages will be processed. Otherwise, the root's level will be used as the effective level.

See *Logging Levels* for a list of levels.

Changed in version 3.2: The *level* parameter now accepts a string representation of the level such as 'INFO' as an alternative to the integer constants such as `INFO`. Note, however, that levels are internally stored as integers, and methods such as e.g. *getEffectiveLevel()* and *isEnabledFor()* will return/expect to be passed integers.

`isEnabledFor`(*lvl*)
Indicates if a message of severity *lvl* would be processed by this logger. This method checks first the module-level level set by `logging.disable(lvl)` and then the logger's effective level as determined by *getEffectiveLevel()*.

`getEffectiveLevel`()
Indicates the effective level for this logger. If a value other than `NOTSET` has been set using *setLevel()*, it is returned. Otherwise, the hierarchy is traversed towards the root until a value other than `NOTSET` is found, and that value is returned. The value returned is an integer, typically one of `logging.DEBUG`, `logging.INFO` etc.

`getChild`(*suffix*)
Returns a logger which is a descendant to this logger, as determined by the suffix. Thus, `logging.getLogger('abc').getChild('def.ghi')` would return the same logger as would be returned by `logging.getLogger('abc.def.ghi')`. This is a convenience method, useful when the parent logger is named using e.g. `__name__` rather than a literal string.

New in version 3.2.

`debug`(*msg*, **args*, ***kwargs*)
Logs a message with level `DEBUG` on this logger. The *msg* is the message format string, and the *args* are the arguments which are merged into *msg* using the string formatting operator. (Note that this means that you can use keywords in the format string, together with a single dictionary argument.)

There are three keyword arguments in *kwargs* which are inspected: *exc_info*, *stack_info*, and *extra*.

If *exc_info* does not evaluate as false, it causes exception information to be added to the logging message. If an exception tuple (in the format returned by *sys.exc_info()*) or an exception instance is provided, it is used; otherwise, *sys.exc_info()* is called to get the exception information.

The second optional keyword argument is *stack_info*, which defaults to `False`. If true, stack information is added to the logging message, including the actual logging call. Note that this is not the same stack information as that displayed through specifying *exc_info*: The former is stack frames from the bottom of the stack up to the logging call in the current thread, whereas the latter is information about stack frames which have been unwound, following an exception, while searching for exception handlers.

You can specify *stack_info* independently of *exc_info*, e.g. to just show how you got to a certain point in your code, even when no exceptions were raised. The stack frames are printed following a header line which says:

```
Stack (most recent call last):
```

This mimics the `Traceback (most recent call last):` which is used when displaying exception frames.

The third keyword argument is *extra* which can be used to pass a dictionary which is used to populate the ___dict___ of the LogRecord created for the logging event with user-defined attributes. These custom attributes can then be used as you like. For example, they could be incorporated into logged messages. For example:

```
FORMAT = '%(asctime)-15s %(clientip)s %(user)-8s %(message)s'
logging.basicConfig(format=FORMAT)
d = {'clientip': '192.168.0.1', 'user': 'fbloggs'}
logger = logging.getLogger('tcpserver')
logger.warning('Protocol problem: %s', 'connection reset', extra=d)
```

would print something like

```
2006-02-08 22:20:02,165 192.168.0.1 fbloggs  Protocol problem: connection reset
```

The keys in the dictionary passed in *extra* should not clash with the keys used by the logging system. (See the *Formatter* documentation for more information on which keys are used by the logging system.)

If you choose to use these attributes in logged messages, you need to exercise some care. In the above example, for instance, the *Formatter* has been set up with a format string which expects 'clientip' and 'user' in the attribute dictionary of the LogRecord. If these are missing, the message will not be logged because a string formatting exception will occur. So in this case, you always need to pass the *extra* dictionary with these keys.

While this might be annoying, this feature is intended for use in specialized circumstances, such as multi-threaded servers where the same code executes in many contexts, and interesting conditions which arise are dependent on this context (such as remote client IP address and authenticated user name, in the above example). In such circumstances, it is likely that specialized *Formatter*s would be used with particular *Handler*s.

New in version 3.2: The *stack_info* parameter was added.

Changed in version 3.5: The *exc_info* parameter can now accept exception instances.

info(*msg*, **args*, ***kwargs*)
Logs a message with level `INFO` on this logger. The arguments are interpreted as for *debug()*.

warning(*msg*, **args*, ***kwargs*)
Logs a message with level `WARNING` on this logger. The arguments are interpreted as for *debug()*.

Note: There is an obsolete method `warn` which is functionally identical to `warning`. As `warn` is deprecated, please do not use it - use `warning` instead.

---

error(*msg*, **args*, ***kwargs*)
Logs a message with level `ERROR` on this logger. The arguments are interpreted as for *debug()*.

critical(*msg*, **args*, ***kwargs*)
Logs a message with level `CRITICAL` on this logger. The arguments are interpreted as for *debug()*.

log(*lvl*, *msg*, **args*, ***kwargs*)
Logs a message with integer level *lvl* on this logger. The other arguments are interpreted as for *debug()*.

exception(*msg*, **args*, ***kwargs*)
Logs a message with level `ERROR` on this logger. The arguments are interpreted as for *debug()*. Exception info is added to the logging message. This method should only be called from an exception handler.

addFilter(*filter*)
Adds the specified filter *filter* to this logger.

removeFilter(*filter*)
Removes the specified filter *filter* from this logger.

filter(*record*)
Applies this logger's filters to the record and returns a true value if the record is to be processed. The filters are consulted in turn, until one of them returns a false value. If none of them return a false value, the record will be processed (passed to handlers). If one returns a false value, no further processing of the record occurs.

addHandler(*hdlr*)
Adds the specified handler *hdlr* to this logger.

removeHandler(*hdlr*)
Removes the specified handler *hdlr* from this logger.

findCaller(*stack_info=False*)
Finds the caller's source filename and line number. Returns the filename, line number, function name and stack information as a 4-element tuple. The stack information is returned as `None` unless *stack_info* is `True`.

handle(*record*)
Handles a record by passing it to all handlers associated with this logger and its ancestors (until a false value of *propagate* is found). This method is used for unpickled records received from a socket, as well as those created locally. Logger-level filtering is applied using *filter()*.

makeRecord(*name*, *lvl*, *fn*, *lno*, *msg*, *args*, *exc_info*, *func=None*, *extra=None*, *sinfo=None*)
This is a factory method which can be overridden in subclasses to create specialized *LogRecord* instances.

hasHandlers()
Checks to see if this logger has any handlers configured. This is done by looking for handlers in this logger and its parents in the logger hierarchy. Returns `True` if a handler was found, else `False`. The method stops searching up the hierarchy whenever a logger with the 'propagate' attribute set to false is found - that will be the last logger which is checked for the existence of handlers.

New in version 3.2.

Changed in version 3.7: Loggers can now be pickled and unpickled.

16.6.2 Logging Levels

The numeric values of logging levels are given in the following table. These are primarily of interest if you want to define your own levels, and need them to have specific values relative to the predefined levels. If you define a level with the same numeric value, it overwrites the predefined value; the predefined name is lost.

Level	Numeric value
CRITICAL	50
ERROR	40
WARNING	30
INFO	20
DEBUG	10
NOTSET	0

16.6.3 Handler Objects

Handlers have the following attributes and methods. Note that *Handler* is never instantiated directly; this class acts as a base for more useful subclasses. However, the `__init__()` method in subclasses needs to call *Handler.__init__()*.

class logging.**Handler**

__init__(*level=NOTSET*)
Initializes the *Handler* instance by setting its level, setting the list of filters to the empty list and creating a lock (using *createLock()*) for serializing access to an I/O mechanism.

createLock()
Initializes a thread lock which can be used to serialize access to underlying I/O functionality which may not be threadsafe.

acquire()
Acquires the thread lock created with *createLock()*.

release()
Releases the thread lock acquired with *acquire()*.

setLevel(*level*)
Sets the threshold for this handler to *level*. Logging messages which are less severe than *level* will be ignored. When a handler is created, the level is set to `NOTSET` (which causes all messages to be processed).

See *Logging Levels* for a list of levels.

Changed in version 3.2: The *level* parameter now accepts a string representation of the level such as 'INFO' as an alternative to the integer constants such as `INFO`.

setFormatter(*fmt*)
Sets the *Formatter* for this handler to *fmt*.

addFilter(*filter*)
Adds the specified filter *filter* to this handler.

removeFilter(*filter*)
Removes the specified filter *filter* from this handler.

filter(*record*)
Applies this handler's filters to the record and returns a true value if the record is to be processed. The filters are consulted in turn, until one of them returns a false value. If none of them return a false value, the record will be emitted. If one returns a false value, the handler will not emit the record.

flush()
Ensure all logging output has been flushed. This version does nothing and is intended to be implemented by subclasses.

close()
Tidy up any resources used by the handler. This version does no output but removes the handler from an internal list of handlers which is closed when *shutdown()* is called. Subclasses should ensure that this gets called from overridden *close()* methods.

handle(*record*)
Conditionally emits the specified logging record, depending on filters which may have been added to the handler. Wraps the actual emission of the record with acquisition/release of the I/O thread lock.

handleError(*record*)
This method should be called from handlers when an exception is encountered during an *emit()* call. If the module-level attribute `raiseExceptions` is `False`, exceptions get silently ignored. This is what is mostly wanted for a logging system - most users will not care about errors in the logging system, they are more interested in application errors. You could, however, replace this with a custom handler if you wish. The specified record is the one which was being processed

when the exception occurred. (The default value of `raiseExceptions` is `True`, as that is more useful during development).

`format`(*record*)
Do formatting for a record - if a formatter is set, use it. Otherwise, use the default formatter for the module.

`emit`(*record*)
Do whatever it takes to actually log the specified logging record. This version is intended to be implemented by subclasses and so raises a *NotImplementedError*.

For a list of handlers included as standard, see *logging.handlers*.

16.6.4 Formatter Objects

Formatter objects have the following attributes and methods. They are responsible for converting a *LogRecord* to (usually) a string which can be interpreted by either a human or an external system. The base *Formatter* allows a formatting string to be specified. If none is supplied, the default value of `'%(message)s'` is used, which just includes the message in the logging call. To have additional items of information in the formatted output (such as a timestamp), keep reading.

A Formatter can be initialized with a format string which makes use of knowledge of the *LogRecord* attributes - such as the default value mentioned above making use of the fact that the user's message and arguments are pre-formatted into a *LogRecord*'s *message* attribute. This format string contains standard Python %-style mapping keys. See section *printf-style String Formatting* for more information on string formatting.

The useful mapping keys in a *LogRecord* are given in the section on *LogRecord attributes*.

`class logging.Formatter`(*fmt=None*, *datefmt=None*, *style='%'*)
Returns a new instance of the *Formatter* class. The instance is initialized with a format string for the message as a whole, as well as a format string for the date/time portion of a message. If no *fmt* is specified, `'%(message)s'` is used. If no *datefmt* is specified, a format is used which is described in the *formatTime()* documentation.

The *style* parameter can be one of '%', '{' or '$' and determines how the format string will be merged with its data: using one of %-formatting, *str.format()* or *string.Template*. See formatting-styles for more information on using {- and $-formatting for log messages.

Changed in version 3.2: The *style* parameter was added.

`format`(*record*)
The record's attribute dictionary is used as the operand to a string formatting operation. Returns the resulting string. Before formatting the dictionary, a couple of preparatory steps are carried out. The *message* attribute of the record is computed using *msg* % *args*. If the formatting string contains `'(asctime)'`, *formatTime()* is called to format the event time. If there is exception information, it is formatted using *formatException()* and appended to the message. Note that the formatted exception information is cached in attribute *exc_text*. This is useful because the exception information can be pickled and sent across the wire, but you should be careful if you have more than one *Formatter* subclass which customizes the formatting of exception information. In this case, you will have to clear the cached value after a formatter has done its formatting, so that the next formatter to handle the event doesn't use the cached value but recalculates it afresh.

If stack information is available, it's appended after the exception information, using *formatStack()* to transform it if necessary.

`formatTime`(*record*, *datefmt=None*)
This method should be called from *format()* by a formatter which wants to make use of a formatted time. This method can be overridden in formatters to provide for any specific requirement, but the basic behavior is as follows: if *datefmt* (a string) is specified, it is used with *time.strftime()* to format the creation time of the record. Otherwise, the format '%Y-%m-%d %H:%M:%S,uuu'

is used, where the uuu part is a millisecond value and the other letters are as per the *time.strftime()* documentation. An example time in this format is `2003-01-23 00:29:50,411`. The resulting string is returned.

This function uses a user-configurable function to convert the creation time to a tuple. By default, *time.localtime()* is used; to change this for a particular formatter instance, set the `converter` attribute to a function with the same signature as *time.localtime()* or *time.gmtime()*. To change it for all formatters, for example if you want all logging times to be shown in GMT, set the `converter` attribute in the `Formatter` class.

Changed in version 3.3: Previously, the default format was hard-coded as in this example: `2010-09-06 22:38:15,292` where the part before the comma is handled by a strptime format string (`'%Y-%m-%d %H:%M:%S'`), and the part after the comma is a millisecond value. Because strptime does not have a format placeholder for milliseconds, the millisecond value is appended using another format string, `'%s,%03d'` — and both of these format strings have been hardcoded into this method. With the change, these strings are defined as class-level attributes which can be overridden at the instance level when desired. The names of the attributes are `default_time_format` (for the strptime format string) and `default_msec_format` (for appending the millisecond value).

formatException(*exc_info*)
Formats the specified exception information (a standard exception tuple as returned by *sys.exc_info()*) as a string. This default implementation just uses *traceback.print_exception()*. The resulting string is returned.

formatStack(*stack_info*)
Formats the specified stack information (a string as returned by *traceback.print_stack()*, but with the last newline removed) as a string. This default implementation just returns the input value.

16.6.5 Filter Objects

`Filters` can be used by `Handlers` and `Loggers` for more sophisticated filtering than is provided by levels. The base filter class only allows events which are below a certain point in the logger hierarchy. For example, a filter initialized with 'A.B' will allow events logged by loggers 'A.B', 'A.B.C', 'A.B.C.D', 'A.B.D' etc. but not 'A.BB', 'B.A.B' etc. If initialized with the empty string, all events are passed.

class logging.Filter(*name=''*)
Returns an instance of the *Filter* class. If *name* is specified, it names a logger which, together with its children, will have its events allowed through the filter. If *name* is the empty string, allows every event.

filter(*record*)
Is the specified record to be logged? Returns zero for no, nonzero for yes. If deemed appropriate, the record may be modified in-place by this method.

Note that filters attached to handlers are consulted before an event is emitted by the handler, whereas filters attached to loggers are consulted whenever an event is logged (using *debug()*, *info()*, etc.), before sending an event to handlers. This means that events which have been generated by descendant loggers will not be filtered by a logger's filter setting, unless the filter has also been applied to those descendant loggers.

You don't actually need to subclass `Filter`: you can pass any instance which has a `filter` method with the same semantics.

Changed in version 3.2: You don't need to create specialized `Filter` classes, or use other classes with a `filter` method: you can use a function (or other callable) as a filter. The filtering logic will check to see if the filter object has a `filter` attribute: if it does, it's assumed to be a `Filter` and its *filter()* method is called. Otherwise, it's assumed to be a callable and called with the record as the single parameter. The returned value should conform to that returned by *filter()*.

Although filters are used primarily to filter records based on more sophisticated criteria than levels, they get to see every record which is processed by the handler or logger they're attached to: this can be useful if you want to do things like counting how many records were processed by a particular logger or handler, or adding, changing or removing attributes in the LogRecord being processed. Obviously changing the LogRecord needs to be done with some care, but it does allow the injection of contextual information into logs (see filters-contextual).

16.6.6 LogRecord Objects

LogRecord instances are created automatically by the *Logger* every time something is logged, and can be created manually via *makeLogRecord()* (for example, from a pickled event received over the wire).

class logging.**LogRecord**(*name*, *level*, *pathname*, *lineno*, *msg*, *args*, *exc_info*, *func=None*, *sinfo=None*)

Contains all the information pertinent to the event being logged.

The primary information is passed in `msg` and `args`, which are combined using `msg % args` to create the `message` field of the record.

Parameters

- **name** – The name of the logger used to log the event represented by this LogRecord. Note that this name will always have this value, even though it may be emitted by a handler attached to a different (ancestor) logger.
- **level** – The numeric level of the logging event (one of DEBUG, INFO etc.) Note that this is converted to *two* attributes of the LogRecord: `levelno` for the numeric value and `levelname` for the corresponding level name.
- **pathname** – The full pathname of the source file where the logging call was made.
- **lineno** – The line number in the source file where the logging call was made.
- **msg** – The event description message, possibly a format string with placeholders for variable data.
- **args** – Variable data to merge into the *msg* argument to obtain the event description.
- **exc_info** – An exception tuple with the current exception information, or `None` if no exception information is available.
- **func** – The name of the function or method from which the logging call was invoked.
- **sinfo** – A text string representing stack information from the base of the stack in the current thread, up to the logging call.

getMessage()

Returns the message for this *LogRecord* instance after merging any user-supplied arguments with the message. If the user-supplied message argument to the logging call is not a string, *str()* is called on it to convert it to a string. This allows use of user-defined classes as messages, whose `__str__` method can return the actual format string to be used.

Changed in version 3.2: The creation of a `LogRecord` has been made more configurable by providing a factory which is used to create the record. The factory can be set using *getLogRecordFactory()* and *setLogRecordFactory()* (see this for the factory's signature).

This functionality can be used to inject your own values into a LogRecord at creation time. You can use the following pattern:

```
old_factory = logging.getLogRecordFactory()

def record_factory(*args, **kwargs):
```

(continues on next page)

(continued from previous page)

```
    record = old_factory(*args, **kwargs)
    record.custom_attribute = 0xdecafbad
    return record

logging.setLogRecordFactory(record_factory)
```

With this pattern, multiple factories could be chained, and as long as they don't overwrite each other's attributes or unintentionally overwrite the standard attributes listed above, there should be no surprises.

16.6.7 LogRecord attributes

The LogRecord has a number of attributes, most of which are derived from the parameters to the constructor. (Note that the names do not always correspond exactly between the LogRecord constructor parameters and the LogRecord attributes.) These attributes can be used to merge data from the record into the format string. The following table lists (in alphabetical order) the attribute names, their meanings and the corresponding placeholder in a %-style format string.

If you are using {}-formatting (*str.format()*), you can use `{attrname}` as the placeholder in the format string. If you are using $-formatting (*string.Template*), use the form `${attrname}`. In both cases, of course, replace `attrname` with the actual attribute name you want to use.

In the case of {}-formatting, you can specify formatting flags by placing them after the attribute name, separated from it with a colon. For example: a placeholder of `{msecs:03d}` would format a millisecond value of `4` as `004`. Refer to the *str.format()* documentation for full details on the options available to you.

Attribute name	Format	Description
args	You shouldn't need to format this yourself.	The tuple of arguments merged into `msg` to produce `message`, or a dict whose values are used for the merge (when there is only one argument, and it is a dictionary).
asctime	`%(asctime)s`	Human-readable time when the *LogRecord* was created. By default this is of the form '2003-07-08 16:49:45,896' (the numbers after the comma are millisecond portion of the time).
created	`%(created)f`	Time when the *LogRecord* was created (as returned by *time.time()*).
exc_info	You shouldn't need to format this yourself.	Exception tuple (à la `sys.exc_info`) or, if no exception has occurred, `None`.
filename	`%(filename)s`	Filename portion of `pathname`.
funcName	`%(funcName)s`	Name of function containing the logging call.
levelname	`%(levelname)s`	Text logging level for the message (`'DEBUG'`, `'INFO'`, `'WARNING'`, `'ERROR'`, `'CRITICAL'`).
levelno	`%(levelno)s`	Numeric logging level for the message (`DEBUG`, `INFO`, `WARNING`, `ERROR`, `CRITICAL`).
lineno	`%(lineno)d`	Source line number where the logging call was issued (if available).
message	`%(message)s`	The logged message, computed as `msg % args`. This is set when *Formatter.format()* is invoked.
module	`%(module)s`	Module (name portion of `filename`).
msecs	`%(msecs)d`	Millisecond portion of the time when the *LogRecord* was created.
msg	You shouldn't need to format this yourself.	The format string passed in the original logging call. Merged with `args` to produce `message`, or an arbitrary object (see arbitrary-object-messages).
name	`%(name)s`	Name of the logger used to log the call.
pathname	`%(pathname)s`	Full pathname of the source file where the logging call was issued (if available).
process	`%(process)d`	Process ID (if available).
processName	`%(processName)s`	Process name (if available).
relativeCreated	`%(relativeCreated)d`	Time in milliseconds when the LogRecord was created, relative to the time the logging module was loaded.
stack_info	You shouldn't need to format this yourself.	Stack frame information (where available) from the bottom of the stack in the current thread, up to and including the stack frame of the logging call which resulted in the creation of this record.
thread	`%(thread)d`	Thread ID (if available).
threadName	`%(threadName)s`	Thread name (if available).

Changed in version 3.1: *processName* was added.

16.6.8 LoggerAdapter Objects

LoggerAdapter instances are used to conveniently pass contextual information into logging calls. For a usage example, see the section on adding contextual information to your logging output.

class logging.LoggerAdapter(*logger*, *extra*)

Returns an instance of *LoggerAdapter* initialized with an underlying *Logger* instance and a dict-like object.

process(*msg*, *kwargs*)

Modifies the message and/or keyword arguments passed to a logging call in order to insert contextual information. This implementation takes the object passed as *extra* to the constructor and adds it to *kwargs* using key 'extra'. The return value is a (*msg*, *kwargs*) tuple which has the (possibly modified) versions of the arguments passed in.

In addition to the above, *LoggerAdapter* supports the following methods of *Logger*: *debug()*, *info()*, *warning()*, *error()*, *exception()*, *critical()*, *log()*, *isEnabledFor()*, *getEffectiveLevel()*, *setLevel()* and *hasHandlers()*. These methods have the same signatures as their counterparts in *Logger*, so you can use the two types of instances interchangeably.

Changed in version 3.2: The *isEnabledFor()*, *getEffectiveLevel()*, *setLevel()* and *hasHandlers()* methods were added to *LoggerAdapter*. These methods delegate to the underlying logger.

16.6.9 Thread Safety

The logging module is intended to be thread-safe without any special work needing to be done by its clients. It achieves this though using threading locks; there is one lock to serialize access to the module's shared data, and each handler also creates a lock to serialize access to its underlying I/O.

If you are implementing asynchronous signal handlers using the *signal* module, you may not be able to use logging from within such handlers. This is because lock implementations in the *threading* module are not always re-entrant, and so cannot be invoked from such signal handlers.

16.6.10 Module-Level Functions

In addition to the classes described above, there are a number of module- level functions.

logging.getLogger(*name=None*)

Return a logger with the specified name or, if name is `None`, return a logger which is the root logger of the hierarchy. If specified, the name is typically a dot-separated hierarchical name like *'a'*, *'a.b'* or *'a.b.c.d'*. Choice of these names is entirely up to the developer who is using logging.

All calls to this function with a given name return the same logger instance. This means that logger instances never need to be passed between different parts of an application.

logging.getLoggerClass()

Return either the standard *Logger* class, or the last class passed to *setLoggerClass()*. This function may be called from within a new class definition, to ensure that installing a customized *Logger* class will not undo customizations already applied by other code. For example:

```
class MyLogger(logging.getLoggerClass()):
    # ... override behaviour here
```

logging.getLogRecordFactory()

Return a callable which is used to create a *LogRecord*.

New in version 3.2: This function has been provided, along with *setLogRecordFactory()*, to allow developers more control over how the *LogRecord* representing a logging event is constructed.

See *setLogRecordFactory()* for more information about the how the factory is called.

logging.**debug**(*msg*, **args*, ***kwargs*)

Logs a message with level DEBUG on the root logger. The *msg* is the message format string, and the *args* are the arguments which are merged into *msg* using the string formatting operator. (Note that this means that you can use keywords in the format string, together with a single dictionary argument.)

There are three keyword arguments in *kwargs* which are inspected: *exc_info* which, if it does not evaluate as false, causes exception information to be added to the logging message. If an exception tuple (in the format returned by *sys.exc_info()*) is provided, it is used; otherwise, *sys.exc_info()* is called to get the exception information.

The second optional keyword argument is *stack_info*, which defaults to False. If true, stack information is added to the logging message, including the actual logging call. Note that this is not the same stack information as that displayed through specifying *exc_info*: The former is stack frames from the bottom of the stack up to the logging call in the current thread, whereas the latter is information about stack frames which have been unwound, following an exception, while searching for exception handlers.

You can specify *stack_info* independently of *exc_info*, e.g. to just show how you got to a certain point in your code, even when no exceptions were raised. The stack frames are printed following a header line which says:

```
Stack (most recent call last):
```

This mimics the Traceback (most recent call last): which is used when displaying exception frames.

The third optional keyword argument is *extra* which can be used to pass a dictionary which is used to populate the ___dict___ of the LogRecord created for the logging event with user-defined attributes. These custom attributes can then be used as you like. For example, they could be incorporated into logged messages. For example:

```
FORMAT = '%(asctime)-15s %(clientip)s %(user)-8s %(message)s'
logging.basicConfig(format=FORMAT)
d = {'clientip': '192.168.0.1', 'user': 'fbloggs'}
logging.warning('Protocol problem: %s', 'connection reset', extra=d)
```

would print something like:

```
2006-02-08 22:20:02,165 192.168.0.1 fbloggs  Protocol problem: connection reset
```

The keys in the dictionary passed in *extra* should not clash with the keys used by the logging system. (See the *Formatter* documentation for more information on which keys are used by the logging system.)

If you choose to use these attributes in logged messages, you need to exercise some care. In the above example, for instance, the *Formatter* has been set up with a format string which expects 'clientip' and 'user' in the attribute dictionary of the LogRecord. If these are missing, the message will not be logged because a string formatting exception will occur. So in this case, you always need to pass the *extra* dictionary with these keys.

While this might be annoying, this feature is intended for use in specialized circumstances, such as multi-threaded servers where the same code executes in many contexts, and interesting conditions which arise are dependent on this context (such as remote client IP address and authenticated user name, in the above example). In such circumstances, it is likely that specialized *Formatter*s would be used with particular *Handler*s.

New in version 3.2: The *stack_info* parameter was added.

logging.**info**(*msg*, **args*, ***kwargs*)

Logs a message with level INFO on the root logger. The arguments are interpreted as for *debug()*.

logging.**warning**(*msg*, **args*, ***kwargs*)
Logs a message with level WARNING on the root logger. The arguments are interpreted as for *debug()*.

Note: There is an obsolete function **warn** which is functionally identical to **warning**. As **warn** is deprecated, please do not use it - use **warning** instead.

---

logging.**error**(*msg*, **args*, ***kwargs*)
Logs a message with level ERROR on the root logger. The arguments are interpreted as for *debug()*.

logging.**critical**(*msg*, **args*, ***kwargs*)
Logs a message with level CRITICAL on the root logger. The arguments are interpreted as for *debug()*.

logging.**exception**(*msg*, **args*, ***kwargs*)
Logs a message with level ERROR on the root logger. The arguments are interpreted as for *debug()*. Exception info is added to the logging message. This function should only be called from an exception handler.

logging.**log**(*level*, *msg*, **args*, ***kwargs*)
Logs a message with level *level* on the root logger. The other arguments are interpreted as for *debug()*.

Note: The above module-level convenience functions, which delegate to the root logger, call *basicConfig()* to ensure that at least one handler is available. Because of this, they should *not* be used in threads, in versions of Python earlier than 2.7.1 and 3.2, unless at least one handler has been added to the root logger *before* the threads are started. In earlier versions of Python, due to a thread safety shortcoming in *basicConfig()*, this can (under rare circumstances) lead to handlers being added multiple times to the root logger, which can in turn lead to multiple messages for the same event.

---

logging.**disable**(*lvl=CRITICAL*)
Provides an overriding level *lvl* for all loggers which takes precedence over the logger's own level. When the need arises to temporarily throttle logging output down across the whole application, this function can be useful. Its effect is to disable all logging calls of severity *lvl* and below, so that if you call it with a value of INFO, then all INFO and DEBUG events would be discarded, whereas those of severity WARNING and above would be processed according to the logger's effective level. If `logging.disable(logging.NOTSET)` is called, it effectively removes this overriding level, so that logging output again depends on the effective levels of individual loggers.

Note that if you have defined any custom logging level higher than CRITICAL (this is not recommended), you won't be able to rely on the default value for the *lvl* parameter, but will have to explicitly supply a suitable value.

Changed in version 3.7: The *lvl* parameter was defaulted to level CRITICAL. See Issue #28524 for more information about this change.

logging.**addLevelName**(*lvl*, *levelName*)
Associates level *lvl* with text *levelName* in an internal dictionary, which is used to map numeric levels to a textual representation, for example when a *Formatter* formats a message. This function can also be used to define your own levels. The only constraints are that all levels used must be registered using this function, levels should be positive integers and they should increase in increasing order of severity.

Note: If you are thinking of defining your own levels, please see the section on custom-levels.

---

logging.**getLevelName**(*lvl*)
Returns the textual representation of logging level *lvl*. If the level is one of the predefined levels CRITICAL, ERROR, WARNING, INFO or DEBUG then you get the corresponding string. If you have associated

levels with names using *addLevelName()* then the name you have associated with *lvl* is returned. If a numeric value corresponding to one of the defined levels is passed in, the corresponding string representation is returned. Otherwise, the string 'Level %s' % lvl is returned.

Note: Levels are internally integers (as they need to be compared in the logging logic). This function is used to convert between an integer level and the level name displayed in the formatted log output by means of the `%(levelname)s` format specifier (see *LogRecord attributes*).

Changed in version 3.4: In Python versions earlier than 3.4, this function could also be passed a text level, and would return the corresponding numeric value of the level. This undocumented behaviour was considered a mistake, and was removed in Python 3.4, but reinstated in 3.4.2 due to retain backward compatibility.

`logging.makeLogRecord(`*attrdict*`)`

Creates and returns a new *LogRecord* instance whose attributes are defined by *attrdict*. This function is useful for taking a pickled *LogRecord* attribute dictionary, sent over a socket, and reconstituting it as a *LogRecord* instance at the receiving end.

`logging.basicConfig(`***kwargs*`)`

Does basic configuration for the logging system by creating a *StreamHandler* with a default *Formatter* and adding it to the root logger. The functions *debug()*, *info()*, *warning()*, *error()* and *critical()* will call *basicConfig()* automatically if no handlers are defined for the root logger.

This function does nothing if the root logger already has handlers configured for it.

Note: This function should be called from the main thread before other threads are started. In versions of Python prior to 2.7.1 and 3.2, if this function is called from multiple threads, it is possible (in rare circumstances) that a handler will be added to the root logger more than once, leading to unexpected results such as messages being duplicated in the log.

The following keyword arguments are supported.

Format	Description
filename	Specifies that a FileHandler be created, using the specified filename, rather than a StreamHandler.
filemode	If *filename* is specified, open the file in this *mode*. Defaults to `'a'`.
format	Use the specified format string for the handler.
datefmt	Use the specified date/time format, as accepted by *time.strftime()*.
style	If *format* is specified, use this style for the format string. One of `'%'`, `'{'` or `'$'` for *printf-style*, *str.format()* or *string.Template* respectively. Defaults to `'%'`.
level	Set the root logger level to the specified *level*.
stream	Use the specified stream to initialize the StreamHandler. Note that this argument is incompatible with *filename* - if both are present, a `ValueError` is raised.
handlers	If specified, this should be an iterable of already created handlers to add to the root logger. Any handlers which don't already have a formatter set will be assigned the default formatter created in this function. Note that this argument is incompatible with *filename* or *stream* - if both are present, a `ValueError` is raised.

Changed in version 3.2: The `style` argument was added.

Changed in version 3.3: The `handlers` argument was added. Additional checks were added to catch situations where incompatible arguments are specified (e.g. `handlers` together with `stream` or `filename`, or `stream` together with `filename`).

logging.**shutdown**()
Informs the logging system to perform an orderly shutdown by flushing and closing all handlers. This should be called at application exit and no further use of the logging system should be made after this call.

logging.**setLoggerClass**(*klass*)
Tells the logging system to use the class *klass* when instantiating a logger. The class should define `__init__()` such that only a name argument is required, and the `__init__()` should call `Logger.__init__()`. This function is typically called before any loggers are instantiated by applications which need to use custom logger behavior.

logging.**setLogRecordFactory**(*factory*)
Set a callable which is used to create a *LogRecord*.

Parameters `factory` – The factory callable to be used to instantiate a log record.

New in version 3.2: This function has been provided, along with *getLogRecordFactory()*, to allow developers more control over how the *LogRecord* representing a logging event is constructed.

The factory has the following signature:

```
factory(name, level, fn, lno, msg, args, exc_info, func=None, sinfo=None, **kwargs)
```

name The logger name.

level The logging level (numeric).

fn The full pathname of the file where the logging call was made.

lno The line number in the file where the logging call was made.

msg The logging message.

args The arguments for the logging message.

exc_info An exception tuple, or `None`.

func The name of the function or method which invoked the logging call.

sinfo A stack traceback such as is provided by *traceback.print_stack()*, showing the call hierarchy.

kwargs Additional keyword arguments.

16.6.11 Module-Level Attributes

logging.**lastResort**
A "handler of last resort" is available through this attribute. This is a *StreamHandler* writing to `sys.stderr` with a level of `WARNING`, and is used to handle logging events in the absence of any logging configuration. The end result is to just print the message to `sys.stderr`. This replaces the earlier error message saying that "no handlers could be found for logger XYZ". If you need the earlier behaviour for some reason, `lastResort` can be set to `None`.

New in version 3.2.

16.6.12 Integration with the warnings module

The *captureWarnings()* function can be used to integrate *logging* with the *warnings* module.

logging.**captureWarnings**(*capture*)
This function is used to turn the capture of warnings by logging on and off.

If *capture* is `True`, warnings issued by the *warnings* module will be redirected to the logging system. Specifically, a warning will be formatted using *warnings.formatwarning()* and the resulting string logged to a logger named `'py.warnings'` with a severity of `WARNING`.

If *capture* is `False`, the redirection of warnings to the logging system will stop, and warnings will be redirected to their original destinations (i.e. those in effect before `captureWarnings(True)` was called).

PEP 282 - A Logging System The proposal which described this feature for inclusion in the Python standard library.

Original Python logging package This is the original source for the *logging* package. The version of the package available from this site is suitable for use with Python 1.5.2, 2.1.x and 2.2.x, which do not include the *logging* package in the standard library.

16.7 `logging.config` — Logging configuration

Source code: Lib/logging/config.py

Important

This page contains only reference information. For tutorials, please see

- Basic Tutorial
- Advanced Tutorial
- Logging Cookbook

This section describes the API for configuring the logging module.

16.7.1 Configuration functions

The following functions configure the logging module. They are located in the *logging.config* module. Their use is optional — you can configure the logging module using these functions or by making calls to the main API (defined in *logging* itself) and defining handlers which are declared either in *logging* or *logging.handlers*.

`logging.config.dictConfig(`*config*`)`

Takes the logging configuration from a dictionary. The contents of this dictionary are described in *Configuration dictionary schema* below.

If an error is encountered during configuration, this function will raise a *ValueError*, *TypeError*, *AttributeError* or *ImportError* with a suitably descriptive message. The following is a (possibly incomplete) list of conditions which will raise an error:

- A `level` which is not a string or which is a string not corresponding to an actual logging level.
- A `propagate` value which is not a boolean.

- An id which does not have a corresponding destination.
- A non-existent handler id found during an incremental call.
- An invalid logger name.
- Inability to resolve to an internal or external object.

Parsing is performed by the `DictConfigurator` class, whose constructor is passed the dictionary used for configuration, and has a `configure()` method. The *logging.config* module has a callable attribute `dictConfigClass` which is initially set to `DictConfigurator`. You can replace the value of `dictConfigClass` with a suitable implementation of your own.

dictConfig() calls `dictConfigClass` passing the specified dictionary, and then calls the `configure()` method on the returned object to put the configuration into effect:

```
def dictConfig(config):
    dictConfigClass(config).configure()
```

For example, a subclass of `DictConfigurator` could call `DictConfigurator.__init__()` in its own `__init__()`, then set up custom prefixes which would be usable in the subsequent `configure()` call. `dictConfigClass` would be bound to this new subclass, and then *dictConfig()* could be called exactly as in the default, uncustomized state.

New in version 3.2.

`logging.config.fileConfig`(*fname*, *defaults=None*, *disable_existing_loggers=True*)

Reads the logging configuration from a *configparser*-format file. The format of the file should be as described in *Configuration file format*. This function can be called several times from an application, allowing an end user to select from various pre-canned configurations (if the developer provides a mechanism to present the choices and load the chosen configuration).

Parameters

- **fname** – A filename, or a file-like object, or an instance derived from *RawConfigParser*. If a `RawConfigParser`-derived instance is passed, it is used as is. Otherwise, a `Configparser` is instantiated, and the configuration read by it from the object passed in `fname`. If that has a *readline()* method, it is assumed to be a file-like object and read using *read_file()*; otherwise, it is assumed to be a filename and passed to *read()*.
- **defaults** – Defaults to be passed to the ConfigParser can be specified in this argument.
- **disable_existing_loggers** – If specified as `False`, loggers which exist when this call is made are left enabled. The default is `True` because this enables old behaviour in a backward-compatible way. This behaviour is to disable any existing loggers unless they or their ancestors are explicitly named in the logging configuration.

Changed in version 3.4: An instance of a subclass of *RawConfigParser* is now accepted as a value for `fname`. This facilitates:

- Use of a configuration file where logging configuration is just part of the overall application configuration.
- Use of a configuration read from a file, and then modified by the using application (e.g. based on command-line parameters or other aspects of the runtime environment) before being passed to `fileConfig`.

`logging.config.listen`(*port=DEFAULT_LOGGING_CONFIG_PORT*, *verify=None*)

Starts up a socket server on the specified port, and listens for new configurations. If no port is specified, the module's default `DEFAULT_LOGGING_CONFIG_PORT` is used. Logging configurations will be sent as a file suitable for processing by *dictConfig()* or *fileConfig()*. Returns a *Thread* instance on which

you can call *start()* to start the server, and which you can *join()* when appropriate. To stop the server, call *stopListening()*.

The `verify` argument, if specified, should be a callable which should verify whether bytes received across the socket are valid and should be processed. This could be done by encrypting and/or signing what is sent across the socket, such that the `verify` callable can perform signature verification and/or decryption. The `verify` callable is called with a single argument - the bytes received across the socket - and should return the bytes to be processed, or `None` to indicate that the bytes should be discarded. The returned bytes could be the same as the passed in bytes (e.g. when only verification is done), or they could be completely different (perhaps if decryption were performed).

To send a configuration to the socket, read in the configuration file and send it to the socket as a sequence of bytes preceded by a four-byte length string packed in binary using `struct.pack('>L', n)`.

Note: Because portions of the configuration are passed through *eval()*, use of this function may open its users to a security risk. While the function only binds to a socket on `localhost`, and so does not accept connections from remote machines, there are scenarios where untrusted code could be run under the account of the process which calls *listen()*. Specifically, if the process calling *listen()* runs on a multi-user machine where users cannot trust each other, then a malicious user could arrange to run essentially arbitrary code in a victim user's process, simply by connecting to the victim's *listen()* socket and sending a configuration which runs whatever code the attacker wants to have executed in the victim's process. This is especially easy to do if the default port is used, but not hard even if a different port is used). To avoid the risk of this happening, use the `verify` argument to *listen()* to prevent unrecognised configurations from being applied.

Changed in version 3.4: The `verify` argument was added.

Note: If you want to send configurations to the listener which don't disable existing loggers, you will need to use a JSON format for the configuration, which will use *dictConfig()* for configuration. This method allows you to specify `disable_existing_loggers` as `False` in the configuration you send.

`logging.config.stopListening()`
Stops the listening server which was created with a call to *listen()*. This is typically called before calling `join()` on the return value from *listen()*.

16.7.2 Configuration dictionary schema

Describing a logging configuration requires listing the various objects to create and the connections between them; for example, you may create a handler named 'console' and then say that the logger named 'startup' will send its messages to the 'console' handler. These objects aren't limited to those provided by the *logging* module because you might write your own formatter or handler class. The parameters to these classes may also need to include external objects such as `sys.stderr`. The syntax for describing these objects and connections is defined in *Object connections* below.

Dictionary Schema Details

The dictionary passed to *dictConfig()* must contain the following keys:

- *version* - to be set to an integer value representing the schema version. The only valid value at present is 1, but having this key allows the schema to evolve while still preserving backwards compatibility.

All other keys are optional, but if present they will be interpreted as described below. In all cases below where a 'configuring dict' is mentioned, it will be checked for the special `'()'` key to see if a custom instantiation is required. If so, the mechanism described in *User-defined objects* below is used to create an instance; otherwise, the context is used to determine what to instantiate.

- *formatters* - the corresponding value will be a dict in which each key is a formatter id and each value is a dict describing how to configure the corresponding *Formatter* instance.

  The configuring dict is searched for keys `format` and `datefmt` (with defaults of `None`) and these are used to construct a *Formatter* instance.

- *filters* - the corresponding value will be a dict in which each key is a filter id and each value is a dict describing how to configure the corresponding Filter instance.

  The configuring dict is searched for the key `name` (defaulting to the empty string) and this is used to construct a *logging.Filter* instance.

- *handlers* - the corresponding value will be a dict in which each key is a handler id and each value is a dict describing how to configure the corresponding Handler instance.

  The configuring dict is searched for the following keys:

  – `class` (mandatory). This is the fully qualified name of the handler class.

  – `level` (optional). The level of the handler.

  – `formatter` (optional). The id of the formatter for this handler.

  – `filters` (optional). A list of ids of the filters for this handler.

  All *other* keys are passed through as keyword arguments to the handler's constructor. For example, given the snippet:

  ```
  handlers:
    console:
      class : logging.StreamHandler
      formatter: brief
      level   : INFO
      filters: [allow_foo]
      stream  : ext://sys.stdout
    file:
      class : logging.handlers.RotatingFileHandler
      formatter: precise
      filename: logconfig.log
      maxBytes: 1024
      backupCount: 3
  ```

  the handler with id `console` is instantiated as a *logging.StreamHandler*, using `sys.stdout` as the underlying stream. The handler with id `file` is instantiated as a *logging.handlers.RotatingFileHandler* with the keyword arguments `filename='logconfig.log', maxBytes=1024, backupCount=3`.

- *loggers* - the corresponding value will be a dict in which each key is a logger name and each value is a dict describing how to configure the corresponding Logger instance.

  The configuring dict is searched for the following keys:

  – `level` (optional). The level of the logger.

  – `propagate` (optional). The propagation setting of the logger.

  – `filters` (optional). A list of ids of the filters for this logger.

  – `handlers` (optional). A list of ids of the handlers for this logger.

The specified loggers will be configured according to the level, propagation, filters and handlers specified.

- *root* - this will be the configuration for the root logger. Processing of the configuration will be as for any logger, except that the `propagate` setting will not be applicable.
- *incremental* - whether the configuration is to be interpreted as incremental to the existing configuration. This value defaults to `False`, which means that the specified configuration replaces the existing configuration with the same semantics as used by the existing *`fileConfig()`* API.

  If the specified value is `True`, the configuration is processed as described in the section on *Incremental Configuration*.
- *disable_existing_loggers* - whether any existing loggers are to be disabled. This setting mirrors the parameter of the same name in *`fileConfig()`*. If absent, this parameter defaults to `True`. This value is ignored if *incremental* is `True`.

Incremental Configuration

It is difficult to provide complete flexibility for incremental configuration. For example, because objects such as filters and formatters are anonymous, once a configuration is set up, it is not possible to refer to such anonymous objects when augmenting a configuration.

Furthermore, there is not a compelling case for arbitrarily altering the object graph of loggers, handlers, filters, formatters at run-time, once a configuration is set up; the verbosity of loggers and handlers can be controlled just by setting levels (and, in the case of loggers, propagation flags). Changing the object graph arbitrarily in a safe way is problematic in a multi-threaded environment; while not impossible, the benefits are not worth the complexity it adds to the implementation.

Thus, when the `incremental` key of a configuration dict is present and is `True`, the system will completely ignore any `formatters` and `filters` entries, and process only the `level` settings in the `handlers` entries, and the `level` and `propagate` settings in the `loggers` and `root` entries.

Using a value in the configuration dict lets configurations to be sent over the wire as pickled dicts to a socket listener. Thus, the logging verbosity of a long-running application can be altered over time with no need to stop and restart the application.

Object connections

The schema describes a set of logging objects - loggers, handlers, formatters, filters - which are connected to each other in an object graph. Thus, the schema needs to represent connections between the objects. For example, say that, once configured, a particular logger has attached to it a particular handler. For the purposes of this discussion, we can say that the logger represents the source, and the handler the destination, of a connection between the two. Of course in the configured objects this is represented by the logger holding a reference to the handler. In the configuration dict, this is done by giving each destination object an id which identifies it unambiguously, and then using the id in the source object's configuration to indicate that a connection exists between the source and the destination object with that id.

So, for example, consider the following YAML snippet:

```
formatters:
  brief:
    # configuration for formatter with id 'brief' goes here
  precise:
    # configuration for formatter with id 'precise' goes here
handlers:
  h1: #This is an id
```

(continues on next page)

(continued from previous page)

```
   # configuration of handler with id 'h1' goes here
   formatter: brief
  h2: #This is another id
   # configuration of handler with id 'h2' goes here
   formatter: precise
loggers:
  foo.bar.baz:
    # other configuration for logger 'foo.bar.baz'
    handlers: [h1, h2]
```

(Note: YAML used here because it's a little more readable than the equivalent Python source form for the dictionary.)

The ids for loggers are the logger names which would be used programmatically to obtain a reference to those loggers, e.g. `foo.bar.baz`. The ids for Formatters and Filters can be any string value (such as `brief`, `precise` above) and they are transient, in that they are only meaningful for processing the configuration dictionary and used to determine connections between objects, and are not persisted anywhere when the configuration call is complete.

The above snippet indicates that logger named `foo.bar.baz` should have two handlers attached to it, which are described by the handler ids `h1` and `h2`. The formatter for `h1` is that described by id `brief`, and the formatter for `h2` is that described by id `precise`.

User-defined objects

The schema supports user-defined objects for handlers, filters and formatters. (Loggers do not need to have different types for different instances, so there is no support in this configuration schema for user-defined logger classes.)

Objects to be configured are described by dictionaries which detail their configuration. In some places, the logging system will be able to infer from the context how an object is to be instantiated, but when a user-defined object is to be instantiated, the system will not know how to do this. In order to provide complete flexibility for user-defined object instantiation, the user needs to provide a 'factory' - a callable which is called with a configuration dictionary and which returns the instantiated object. This is signalled by an absolute import path to the factory being made available under the special key `'()'`. Here's a concrete example:

```
formatters:
  brief:
    format: '%(message)s'
  default:
    format: '%(asctime)s %(levelname)-8s %(name)-15s %(message)s'
    datefmt: '%Y-%m-%d %H:%M:%S'
  custom:
      (): my.package.customFormatterFactory
      bar: baz
      spam: 99.9
      answer: 42
```

The above YAML snippet defines three formatters. The first, with id `brief`, is a standard *logging.Formatter* instance with the specified format string. The second, with id `default`, has a longer format and also defines the time format explicitly, and will result in a *logging.Formatter* initialized with those two format strings. Shown in Python source form, the `brief` and `default` formatters have configuration sub-dictionaries:

```
{
  'format' : '%(message)s'
}
```

and:

```
{
  'format' : '%(asctime)s %(levelname)-8s %(name)-15s %(message)s',
  'datefmt' : '%Y-%m-%d %H:%M:%S'
}
```

respectively, and as these dictionaries do not contain the special key `'()'`, the instantiation is inferred from the context: as a result, standard *logging.Formatter* instances are created. The configuration sub-dictionary for the third formatter, with id `custom`, is:

```
{
  '()' : 'my.package.customFormatterFactory',
  'bar' : 'baz',
  'spam' : 99.9,
  'answer' : 42
}
```

and this contains the special key `'()'`, which means that user-defined instantiation is wanted. In this case, the specified factory callable will be used. If it is an actual callable it will be used directly - otherwise, if you specify a string (as in the example) the actual callable will be located using normal import mechanisms. The callable will be called with the **remaining** items in the configuration sub-dictionary as keyword arguments. In the above example, the formatter with id `custom` will be assumed to be returned by the call:

```
my.package.customFormatterFactory(bar='baz', spam=99.9, answer=42)
```

The key `'()'` has been used as the special key because it is not a valid keyword parameter name, and so will not clash with the names of the keyword arguments used in the call. The `'()'` also serves as a mnemonic that the corresponding value is a callable.

Access to external objects

There are times where a configuration needs to refer to objects external to the configuration, for example `sys.stderr`. If the configuration dict is constructed using Python code, this is straightforward, but a problem arises when the configuration is provided via a text file (e.g. JSON, YAML). In a text file, there is no standard way to distinguish `sys.stderr` from the literal string `'sys.stderr'`. To facilitate this distinction, the configuration system looks for certain special prefixes in string values and treat them specially. For example, if the literal string `'ext://sys.stderr'` is provided as a value in the configuration, then the `ext://` will be stripped off and the remainder of the value processed using normal import mechanisms.

The handling of such prefixes is done in a way analogous to protocol handling: there is a generic mechanism to look for prefixes which match the regular expression `^(?P<prefix>[a-z]+)://(?P<suffix>.*)$` whereby, if the `prefix` is recognised, the `suffix` is processed in a prefix-dependent manner and the result of the processing replaces the string value. If the prefix is not recognised, then the string value will be left as-is.

Access to internal objects

As well as external objects, there is sometimes also a need to refer to objects in the configuration. This will be done implicitly by the configuration system for things that it knows about. For example, the string value `'DEBUG'` for a `level` in a logger or handler will automatically be converted to the value `logging.DEBUG`,

and the handlers, filters and formatter entries will take an object id and resolve to the appropriate destination object.

However, a more generic mechanism is needed for user-defined objects which are not known to the *logging* module. For example, consider *logging.handlers.MemoryHandler*, which takes a target argument which is another handler to delegate to. Since the system already knows about this class, then in the configuration, the given target just needs to be the object id of the relevant target handler, and the system will resolve to the handler from the id. If, however, a user defines a my.package.MyHandler which has an alternate handler, the configuration system would not know that the alternate referred to a handler. To cater for this, a generic resolution system allows the user to specify:

```
handlers:
  file:
    # configuration of file handler goes here

  custom:
    (): my.package.MyHandler
    alternate: cfg://handlers.file
```

The literal string 'cfg://handlers.file' will be resolved in an analogous way to strings with the ext:// prefix, but looking in the configuration itself rather than the import namespace. The mechanism allows access by dot or by index, in a similar way to that provided by str.format. Thus, given the following snippet:

```
handlers:
  email:
    class: logging.handlers.SMTPHandler
    mailhost: localhost
    fromaddr: my_app@domain.tld
    toaddrs:
      - support_team@domain.tld
      - dev_team@domain.tld
    subject: Houston, we have a problem.
```

in the configuration, the string 'cfg://handlers' would resolve to the dict with key handlers, the string 'cfg://handlers.email would resolve to the dict with key email in the handlers dict, and so on. The string 'cfg://handlers.email.toaddrs[1] would resolve to 'dev_team.domain.tld' and the string 'cfg://handlers.email.toaddrs[0]' would resolve to the value 'support_team@domain.tld'. The subject value could be accessed using either 'cfg://handlers.email.subject' or, equivalently, 'cfg://handlers.email[subject]'. The latter form only needs to be used if the key contains spaces or non-alphanumeric characters. If an index value consists only of decimal digits, access will be attempted using the corresponding integer value, falling back to the string value if needed.

Given a string cfg://handlers.myhandler.mykey.123, this will resolve to config_dict['handlers']['myhandler']['mykey']['123']. If the string is specified as cfg://handlers.myhandler.mykey[123], the system will attempt to retrieve the value from config_dict['handlers']['myhandler']['mykey'][123], and fall back to config_dict['handlers']['myhandler']['mykey']['123'] if that fails.

Import resolution and custom importers

Import resolution, by default, uses the builtin *__import__()* function to do its importing. You may want to replace this with your own importing mechanism: if so, you can replace the importer attribute of the DictConfigurator or its superclass, the BaseConfigurator class. However, you need to be careful because of the way functions are accessed from classes via descriptors. If you are using a Python callable to do your imports, and you want to define it at class level rather than instance level, you need to wrap it with *staticmethod()*. For example:

```
from importlib import import_module
from logging.config import BaseConfigurator

BaseConfigurator.importer = staticmethod(import_module)
```

You don't need to wrap with *staticmethod()* if you're setting the import callable on a configurator *instance*.

16.7.3 Configuration file format

The configuration file format understood by *fileConfig()* is based on *configparser* functionality. The file must contain sections called `[loggers]`, `[handlers]` and `[formatters]` which identify by name the entities of each type which are defined in the file. For each such entity, there is a separate section which identifies how that entity is configured. Thus, for a logger named `log01` in the `[loggers]` section, the relevant configuration details are held in a section `[logger_log01]`. Similarly, a handler called `hand01` in the `[handlers]` section will have its configuration held in a section called `[handler_hand01]`, while a formatter called `form01` in the `[formatters]` section will have its configuration specified in a section called `[formatter_form01]`. The root logger configuration must be specified in a section called `[logger_root]`.

Note: The *fileConfig()* API is older than the *dictConfig()* API and does not provide functionality to cover certain aspects of logging. For example, you cannot configure *Filter* objects, which provide for filtering of messages beyond simple integer levels, using *fileConfig()*. If you need to have instances of *Filter* in your logging configuration, you will need to use *dictConfig()*. Note that future enhancements to configuration functionality will be added to *dictConfig()*, so it's worth considering transitioning to this newer API when it's convenient to do so.

Examples of these sections in the file are given below.

```
[loggers]
keys=root,log02,log03,log04,log05,log06,log07

[handlers]
keys=hand01,hand02,hand03,hand04,hand05,hand06,hand07,hand08,hand09

[formatters]
keys=form01,form02,form03,form04,form05,form06,form07,form08,form09
```

The root logger must specify a level and a list of handlers. An example of a root logger section is given below.

```
[logger_root]
level=NOTSET
handlers=hand01
```

The `level` entry can be one of `DEBUG, INFO, WARNING, ERROR, CRITICAL` or `NOTSET`. For the root logger only, `NOTSET` means that all messages will be logged. Level values are *eval()*uated in the context of the `logging` package's namespace.

The `handlers` entry is a comma-separated list of handler names, which must appear in the `[handlers]` section. These names must appear in the `[handlers]` section and have corresponding sections in the configuration file.

For loggers other than the root logger, some additional information is required. This is illustrated by the following example.

```
[logger_parser]
level=DEBUG
handlers=hand01
propagate=1
qualname=compiler.parser
```

The `level` and `handlers` entries are interpreted as for the root logger, except that if a non-root logger's level is specified as `NOTSET`, the system consults loggers higher up the hierarchy to determine the effective level of the logger. The `propagate` entry is set to 1 to indicate that messages must propagate to handlers higher up the logger hierarchy from this logger, or 0 to indicate that messages are **not** propagated to handlers up the hierarchy. The `qualname` entry is the hierarchical channel name of the logger, that is to say the name used by the application to get the logger.

Sections which specify handler configuration are exemplified by the following.

```
[handler_hand01]
class=StreamHandler
level=NOTSET
formatter=form01
args=(sys.stdout,)
```

The `class` entry indicates the handler's class (as determined by *eval()* in the `logging` package's namespace). The `level` is interpreted as for loggers, and `NOTSET` is taken to mean 'log everything'.

The `formatter` entry indicates the key name of the formatter for this handler. If blank, a default formatter (`logging._defaultFormatter`) is used. If a name is specified, it must appear in the `[formatters]` section and have a corresponding section in the configuration file.

The `args` entry, when *eval()*uated in the context of the `logging` package's namespace, is the list of arguments to the constructor for the handler class. Refer to the constructors for the relevant handlers, or to the examples below, to see how typical entries are constructed. If not provided, it defaults to `()`.

The optional `kwargs` entry, when *eval()*uated in the context of the `logging` package's namespace, is the keyword argument dict to the constructor for the handler class. If not provided, it defaults to `{}`.

```
[handler_hand02]
class=FileHandler
level=DEBUG
formatter=form02
args=('python.log', 'w')

[handler_hand03]
class=handlers.SocketHandler
level=INFO
formatter=form03
args=('localhost', handlers.DEFAULT_TCP_LOGGING_PORT)

[handler_hand04]
class=handlers.DatagramHandler
level=WARN
formatter=form04
args=('localhost', handlers.DEFAULT_UDP_LOGGING_PORT)

[handler_hand05]
class=handlers.SysLogHandler
level=ERROR
formatter=form05
args=(('localhost', handlers.SYSLOG_UDP_PORT), handlers.SysLogHandler.LOG_USER)
```

(continues on next page)

(continued from previous page)

```
[handler_hand06]
class=handlers.NTEventLogHandler
level=CRITICAL
formatter=form06
args=('Python Application', '', 'Application')

[handler_hand07]
class=handlers.SMTPHandler
level=WARN
formatter=form07
args=('localhost', 'from@abc', ['user1@abc', 'user2@xyz'], 'Logger Subject')
kwargs={'timeout': 10.0}

[handler_hand08]
class=handlers.MemoryHandler
level=NOTSET
formatter=form08
target=
args=(10, ERROR)

[handler_hand09]
class=handlers.HTTPHandler
level=NOTSET
formatter=form09
args=('localhost:9022', '/log', 'GET')
kwargs={'secure': True}
```

Sections which specify formatter configuration are typified by the following.

```
[formatter_form01]
format=F1 %(asctime)s %(levelname)s %(message)s
datefmt=
class=logging.Formatter
```

The `format` entry is the overall format string, and the `datefmt` entry is the `strftime()`-compatible date/time format string. If empty, the package substitutes something which is almost equivalent to specifying the date format string `'%Y-%m-%d %H:%M:%S'`. This format also specifies milliseconds, which are appended to the result of using the above format string, with a comma separator. An example time in this format is `2003-01-23 00:29:50,411`.

The `class` entry is optional. It indicates the name of the formatter's class (as a dotted module and class name.) This option is useful for instantiating a *Formatter* subclass. Subclasses of *Formatter* can present exception tracebacks in an expanded or condensed format.

Note: Due to the use of *eval()* as described above, there are potential security risks which result from using the *listen()* to send and receive configurations via sockets. The risks are limited to where multiple users with no mutual trust run code on the same machine; see the *listen()* documentation for more information.

16.8 logging.handlers — Logging handlers

Source code: Lib/logging/handlers.py

Important

This page contains only reference information. For tutorials, please see

- Basic Tutorial
- Advanced Tutorial
- Logging Cookbook

The following useful handlers are provided in the package. Note that three of the handlers (*StreamHandler*, *FileHandler* and *NullHandler*) are actually defined in the *logging* module itself, but have been documented here along with the other handlers.

16.8.1 StreamHandler

The *StreamHandler* class, located in the core *logging* package, sends logging output to streams such as *sys.stdout*, *sys.stderr* or any file-like object (or, more precisely, any object which supports `write()` and `flush()` methods).

class logging.**StreamHandler**(*stream=None*)

Returns a new instance of the *StreamHandler* class. If *stream* is specified, the instance will use it for logging output; otherwise, *sys.stderr* will be used.

emit(*record*)

If a formatter is specified, it is used to format the record. The record is then written to the stream with a terminator. If exception information is present, it is formatted using *traceback.print_exception()* and appended to the stream.

flush()

Flushes the stream by calling its *flush()* method. Note that the `close()` method is inherited from *Handler* and so does no output, so an explicit *flush()* call may be needed at times.

setStream(*stream*)

Sets the instance's stream to the specified value, if it is different. The old stream is flushed before the new stream is set.

Parameters **stream** – The stream that the handler should use.

Returns the old stream, if the stream was changed, or *None* if it wasn't.

New in version 3.7.

Changed in version 3.2: The `StreamHandler` class now has a `terminator` attribute, default value `'\n'`, which is used as the terminator when writing a formatted record to a stream. If you don't want this newline termination, you can set the handler instance's `terminator` attribute to the empty string. In earlier versions, the terminator was hardcoded as `'\n'`.

16.8.2 FileHandler

The *FileHandler* class, located in the core *logging* package, sends logging output to a disk file. It inherits the output functionality from *StreamHandler*.

class logging.FileHandler(*filename*, *mode='a'*, *encoding=None*, *delay=False*)
Returns a new instance of the *FileHandler* class. The specified file is opened and used as the stream for logging. If *mode* is not specified, `'a'` is used. If *encoding* is not `None`, it is used to open the file with that encoding. If *delay* is true, then file opening is deferred until the first call to *emit()*. By default, the file grows indefinitely.

Changed in version 3.6: As well as string values, *Path* objects are also accepted for the *filename* argument.

close()
Closes the file.

emit(*record*)
Outputs the record to the file.

16.8.3 NullHandler

New in version 3.1.

The *NullHandler* class, located in the core *logging* package, does not do any formatting or output. It is essentially a 'no-op' handler for use by library developers.

class logging.NullHandler
Returns a new instance of the *NullHandler* class.

emit(*record*)
This method does nothing.

handle(*record*)
This method does nothing.

createLock()
This method returns `None` for the lock, since there is no underlying I/O to which access needs to be serialized.

See library-config for more information on how to use *NullHandler*.

16.8.4 WatchedFileHandler

The *WatchedFileHandler* class, located in the *logging.handlers* module, is a `FileHandler` which watches the file it is logging to. If the file changes, it is closed and reopened using the file name.

A file change can happen because of usage of programs such as *newsyslog* and *logrotate* which perform log file rotation. This handler, intended for use under Unix/Linux, watches the file to see if it has changed since the last emit. (A file is deemed to have changed if its device or inode have changed.) If the file has changed, the old file stream is closed, and the file opened to get a new stream.

This handler is not appropriate for use under Windows, because under Windows open log files cannot be moved or renamed - logging opens the files with exclusive locks - and so there is no need for such a handler. Furthermore, *ST_INO* is not supported under Windows; *stat()* always returns zero for this value.

class logging.handlers.WatchedFileHandler(*filename*, *mode='a'*, *encoding=None*, *delay=False*)
Returns a new instance of the *WatchedFileHandler* class. The specified file is opened and used as the stream for logging. If *mode* is not specified, `'a'` is used. If *encoding* is not `None`, it is used to open the file with that encoding. If *delay* is true, then file opening is deferred until the first call to *emit()*. By default, the file grows indefinitely.

Changed in version 3.6: As well as string values, *Path* objects are also accepted for the *filename* argument.

reopenIfNeeded()
Checks to see if the file has changed. If it has, the existing stream is flushed and closed and the file opened again, typically as a precursor to outputting the record to the file.

New in version 3.6.

emit(*record*)
Outputs the record to the file, but first calls *reopenIfNeeded()* to reopen the file if it has changed.

16.8.5 BaseRotatingHandler

The *BaseRotatingHandler* class, located in the *logging.handlers* module, is the base class for the rotating file handlers, *RotatingFileHandler* and *TimedRotatingFileHandler*. You should not need to instantiate this class, but it has attributes and methods you may need to override.

class logging.handlers.BaseRotatingHandler(*filename*, *mode*, *encoding=None*, *delay=False*)
The parameters are as for **FileHandler**. The attributes are:

namer
If this attribute is set to a callable, the *rotation_filename()* method delegates to this callable. The parameters passed to the callable are those passed to *rotation_filename()*.

Note: The namer function is called quite a few times during rollover, so it should be as simple and as fast as possible. It should also return the same output every time for a given input, otherwise the rollover behaviour may not work as expected.

New in version 3.3.

rotator
If this attribute is set to a callable, the *rotate()* method delegates to this callable. The parameters passed to the callable are those passed to *rotate()*.

New in version 3.3.

rotation_filename(*default_name*)
Modify the filename of a log file when rotating.

This is provided so that a custom filename can be provided.

The default implementation calls the 'namer' attribute of the handler, if it's callable, passing the default name to it. If the attribute isn't callable (the default is **None**), the name is returned unchanged.

Parameters **default_name** – The default name for the log file.

New in version 3.3.

rotate(*source*, *dest*)
When rotating, rotate the current log.

The default implementation calls the 'rotator' attribute of the handler, if it's callable, passing the source and dest arguments to it. If the attribute isn't callable (the default is **None**), the source is simply renamed to the destination.

Parameters

- **source** – The source filename. This is normally the base filename, e.g. 'test.log'.
- **dest** – The destination filename. This is normally what the source is rotated to, e.g. 'test.log.1'.

New in version 3.3.

The reason the attributes exist is to save you having to subclass - you can use the same callables for instances of *RotatingFileHandler* and *TimedRotatingFileHandler*. If either the namer or rotator callable raises an exception, this will be handled in the same way as any other exception during an `emit()` call, i.e. via the `handleError()` method of the handler.

If you need to make more significant changes to rotation processing, you can override the methods.

For an example, see cookbook-rotator-namer.

16.8.6 RotatingFileHandler

The *RotatingFileHandler* class, located in the *logging.handlers* module, supports rotation of disk log files.

class logging.handlers.**RotatingFileHandler**(*filename*, *mode='a'*, *maxBytes=0*, *backupCount=0*, *encoding=None*, *delay=False*)

Returns a new instance of the *RotatingFileHandler* class. The specified file is opened and used as the stream for logging. If *mode* is not specified, `'a'` is used. If *encoding* is not `None`, it is used to open the file with that encoding. If *delay* is true, then file opening is deferred until the first call to *emit()*. By default, the file grows indefinitely.

You can use the *maxBytes* and *backupCount* values to allow the file to *rollover* at a predetermined size. When the size is about to be exceeded, the file is closed and a new file is silently opened for output. Rollover occurs whenever the current log file is nearly *maxBytes* in length; but if either of *maxBytes* or *backupCount* is zero, rollover never occurs, so you generally want to set *backupCount* to at least 1, and have a non-zero *maxBytes*. When *backupCount* is non-zero, the system will save old log files by appending the extensions '.1', '.2' etc., to the filename. For example, with a *backupCount* of 5 and a base file name of `app.log`, you would get `app.log`, `app.log.1`, `app.log.2`, up to `app.log.5`. The file being written to is always `app.log`. When this file is filled, it is closed and renamed to `app.log.1`, and if files `app.log.1`, `app.log.2`, etc. exist, then they are renamed to `app.log.2`, `app.log.3` etc. respectively.

Changed in version 3.6: As well as string values, *Path* objects are also accepted for the *filename* argument.

doRollover()

Does a rollover, as described above.

emit(*record*)

Outputs the record to the file, catering for rollover as described previously.

16.8.7 TimedRotatingFileHandler

The *TimedRotatingFileHandler* class, located in the *logging.handlers* module, supports rotation of disk log files at certain timed intervals.

class logging.handlers.**TimedRotatingFileHandler**(*filename*, *when='h'*, *interval=1*, *backupCount=0*, *encoding=None*, *delay=False*, *utc=False*, *atTime=None*)

Returns a new instance of the *TimedRotatingFileHandler* class. The specified file is opened and used as the stream for logging. On rotating it also sets the filename suffix. Rotating happens based on the product of *when* and *interval*.

You can use the *when* to specify the type of *interval*. The list of possible values is below. Note that they are not case sensitive.

Value	Type of interval	If/how *atTime* is used
`'S'`	Seconds	Ignored
`'M'`	Minutes	Ignored
`'H'`	Hours	Ignored
`'D'`	Days	Ignored
`'W0'-'W6'`	Weekday (0=Monday)	Used to compute initial rollover time
`'midnight'`	Roll over at midnight, if *atTime* not specified, else at time *atTime*	Used to compute initial rollover time

When using weekday-based rotation, specify 'W0' for Monday, 'W1' for Tuesday, and so on up to 'W6' for Sunday. In this case, the value passed for *interval* isn't used.

The system will save old log files by appending extensions to the filename. The extensions are date-and-time based, using the strftime format `%Y-%m-%d_%H-%M-%S` or a leading portion thereof, depending on the rollover interval.

When computing the next rollover time for the first time (when the handler is created), the last modification time of an existing log file, or else the current time, is used to compute when the next rotation will occur.

If the *utc* argument is true, times in UTC will be used; otherwise local time is used.

If *backupCount* is nonzero, at most *backupCount* files will be kept, and if more would be created when rollover occurs, the oldest one is deleted. The deletion logic uses the interval to determine which files to delete, so changing the interval may leave old files lying around.

If *delay* is true, then file opening is deferred until the first call to *emit()*.

If *atTime* is not `None`, it must be a `datetime.time` instance which specifies the time of day when rollover occurs, for the cases where rollover is set to happen "at midnight" or "on a particular weekday". Note that in these cases, the *atTime* value is effectively used to compute the *initial* rollover, and subsequent rollovers would be calculated via the normal interval calculation.

Note: Calculation of the initial rollover time is done when the handler is initialised. Calculation of subsequent rollover times is done only when rollover occurs, and rollover occurs only when emitting output. If this is not kept in mind, it might lead to some confusion. For example, if an interval of "every minute" is set, that does not mean you will always see log files with times (in the filename) separated by a minute; if, during application execution, logging output is generated more frequently than once a minute, *then* you can expect to see log files with times separated by a minute. If, on the other hand, logging messages are only output once every five minutes (say), then there will be gaps in the file times corresponding to the minutes where no output (and hence no rollover) occurred.

Changed in version 3.4: *atTime* parameter was added.

Changed in version 3.6: As well as string values, *Path* objects are also accepted for the *filename* argument.

`doRollover()`
Does a rollover, as described above.

`emit(`*record***`)`**
Outputs the record to the file, catering for rollover as described above.

16.8.8 SocketHandler

The *SocketHandler* class, located in the *logging.handlers* module, sends logging output to a network socket. The base class uses a TCP socket.

class logging.handlers.SocketHandler(*host*, *port*)

Returns a new instance of the *SocketHandler* class intended to communicate with a remote machine whose address is given by *host* and *port*.

Changed in version 3.4: If `port` is specified as `None`, a Unix domain socket is created using the value in `host` - otherwise, a TCP socket is created.

close()

Closes the socket.

emit()

Pickles the record's attribute dictionary and writes it to the socket in binary format. If there is an error with the socket, silently drops the packet. If the connection was previously lost, re-establishes the connection. To unpickle the record at the receiving end into a *LogRecord*, use the *makeLogRecord()* function.

handleError()

Handles an error which has occurred during *emit()*. The most likely cause is a lost connection. Closes the socket so that we can retry on the next event.

makeSocket()

This is a factory method which allows subclasses to define the precise type of socket they want. The default implementation creates a TCP socket (*socket.SOCK_STREAM*).

makePickle(*record*)

Pickles the record's attribute dictionary in binary format with a length prefix, and returns it ready for transmission across the socket.

Note that pickles aren't completely secure. If you are concerned about security, you may want to override this method to implement a more secure mechanism. For example, you can sign pickles using HMAC and then verify them on the receiving end, or alternatively you can disable unpickling of global objects on the receiving end.

send(*packet*)

Send a pickled string *packet* to the socket. This function allows for partial sends which can happen when the network is busy.

createSocket()

Tries to create a socket; on failure, uses an exponential back-off algorithm. On initial failure, the handler will drop the message it was trying to send. When subsequent messages are handled by the same instance, it will not try connecting until some time has passed. The default parameters are such that the initial delay is one second, and if after that delay the connection still can't be made, the handler will double the delay each time up to a maximum of 30 seconds.

This behaviour is controlled by the following handler attributes:

- `retryStart` (initial delay, defaulting to 1.0 seconds).
- `retryFactor` (multiplier, defaulting to 2.0).
- `retryMax` (maximum delay, defaulting to 30.0 seconds).

This means that if the remote listener starts up *after* the handler has been used, you could lose messages (since the handler won't even attempt a connection until the delay has elapsed, but just silently drop messages during the delay period).

16.8.9 DatagramHandler

The *DatagramHandler* class, located in the *logging.handlers* module, inherits from *SocketHandler* to support sending logging messages over UDP sockets.

class logging.handlers.DatagramHandler(*host*, *port*)

Returns a new instance of the *DatagramHandler* class intended to communicate with a remote machine whose address is given by *host* and *port*.

Changed in version 3.4: If `port` is specified as `None`, a Unix domain socket is created using the value in `host` - otherwise, a UDP socket is created.

emit()

Pickles the record's attribute dictionary and writes it to the socket in binary format. If there is an error with the socket, silently drops the packet. To unpickle the record at the receiving end into a *LogRecord*, use the *makeLogRecord()* function.

makeSocket()

The factory method of *SocketHandler* is here overridden to create a UDP socket (*socket.SOCK_DGRAM*).

send(*s*)

Send a pickled string to a socket.

16.8.10 SysLogHandler

The *SysLogHandler* class, located in the *logging.handlers* module, supports sending logging messages to a remote or local Unix syslog.

class logging.handlers.SysLogHandler(*address=('localhost', SYSLOG_UDP_PORT)*, *facility=LOG_USER*, *socktype=socket.SOCK_DGRAM*)

Returns a new instance of the *SysLogHandler* class intended to communicate with a remote Unix machine whose address is given by *address* in the form of a `(host, port)` tuple. If *address* is not specified, `('localhost', 514)` is used. The address is used to open a socket. An alternative to providing a `(host, port)` tuple is providing an address as a string, for example '/dev/log'. In this case, a Unix domain socket is used to send the message to the syslog. If *facility* is not specified, `LOG_USER` is used. The type of socket opened depends on the *socktype* argument, which defaults to *socket.SOCK_DGRAM* and thus opens a UDP socket. To open a TCP socket (for use with the newer syslog daemons such as rsyslog), specify a value of *socket.SOCK_STREAM*.

Note that if your server is not listening on UDP port 514, *SysLogHandler* may appear not to work. In that case, check what address you should be using for a domain socket - it's system dependent. For example, on Linux it's usually '/dev/log' but on OS/X it's '/var/run/syslog'. You'll need to check your platform and use the appropriate address (you may need to do this check at runtime if your application needs to run on several platforms). On Windows, you pretty much have to use the UDP option.

Changed in version 3.2: *socktype* was added.

close()

Closes the socket to the remote host.

emit(*record*)

The record is formatted, and then sent to the syslog server. If exception information is present, it is *not* sent to the server.

Changed in version 3.2.1: (See: bpo-12168.) In earlier versions, the message sent to the syslog daemons was always terminated with a NUL byte, because early versions of these daemons expected a NUL terminated message - even though it's not in the relevant specification (**RFC 5424**). More recent versions of these daemons don't expect the NUL byte but strip it off if it's

there, and even more recent daemons (which adhere more closely to RFC 5424) pass the NUL byte on as part of the message.

To enable easier handling of syslog messages in the face of all these differing daemon behaviours, the appending of the NUL byte has been made configurable, through the use of a class-level attribute, `append_nul`. This defaults to `True` (preserving the existing behaviour) but can be set to `False` on a `SysLogHandler` instance in order for that instance to *not* append the NUL terminator.

Changed in version 3.3: (See: bpo-12419.) In earlier versions, there was no facility for an "ident" or "tag" prefix to identify the source of the message. This can now be specified using a class-level attribute, defaulting to `""` to preserve existing behaviour, but which can be overridden on a `SysLogHandler` instance in order for that instance to prepend the ident to every message handled. Note that the provided ident must be text, not bytes, and is prepended to the message exactly as is.

`encodePriority`(*facility*, *priority*)

Encodes the facility and priority into an integer. You can pass in strings or integers - if strings are passed, internal mapping dictionaries are used to convert them to integers.

The symbolic `LOG_` values are defined in *SysLogHandler* and mirror the values defined in the `sys/syslog.h` header file.

Priorities

Name (string)	Symbolic value
`alert`	LOG_ALERT
`crit` or `critical`	LOG_CRIT
`debug`	LOG_DEBUG
`emerg` or `panic`	LOG_EMERG
`err` or `error`	LOG_ERR
`info`	LOG_INFO
`notice`	LOG_NOTICE
`warn` or `warning`	LOG_WARNING

Facilities

Name (string)	Symbolic value
auth	LOG_AUTH
authpriv	LOG_AUTHPRIV
cron	LOG_CRON
daemon	LOG_DAEMON
ftp	LOG_FTP
kern	LOG_KERN
lpr	LOG_LPR
mail	LOG_MAIL
news	LOG_NEWS
syslog	LOG_SYSLOG
user	LOG_USER
uucp	LOG_UUCP
local0	LOG_LOCAL0
local1	LOG_LOCAL1
local2	LOG_LOCAL2
local3	LOG_LOCAL3
local4	LOG_LOCAL4
local5	LOG_LOCAL5
local6	LOG_LOCAL6
local7	LOG_LOCAL7

mapPriority(*levelname*)

Maps a logging level name to a syslog priority name. You may need to override this if you are using custom levels, or if the default algorithm is not suitable for your needs. The default algorithm maps `DEBUG`, `INFO`, `WARNING`, `ERROR` and `CRITICAL` to the equivalent syslog names, and all other level names to 'warning'.

16.8.11 NTEventLogHandler

The *NTEventLogHandler* class, located in the *logging.handlers* module, supports sending logging messages to a local Windows NT, Windows 2000 or Windows XP event log. Before you can use it, you need Mark Hammond's Win32 extensions for Python installed.

class logging.handlers.**NTEventLogHandler**(*appname*, *dllname=None*, *logtype='Application'*)

Returns a new instance of the *NTEventLogHandler* class. The *appname* is used to define the application name as it appears in the event log. An appropriate registry entry is created using this name. The *dllname* should give the fully qualified pathname of a .dll or .exe which contains message definitions to hold in the log (if not specified, `'win32service.pyd'` is used - this is installed with the Win32 extensions and contains some basic placeholder message definitions. Note that use of these placeholders will make your event logs big, as the entire message source is held in the log. If you want slimmer logs, you have to pass in the name of your own .dll or .exe which contains the message definitions you want to use in the event log). The *logtype* is one of `'Application'`, `'System'` or `'Security'`, and defaults to `'Application'`.

close()

At this point, you can remove the application name from the registry as a source of event log entries. However, if you do this, you will not be able to see the events as you intended in the Event Log Viewer - it needs to be able to access the registry to get the .dll name. The current version does not do this.

emit(*record*)

Determines the message ID, event category and event type, and then logs the message in the NT event log.

`getEventCategory`(*record*)
Returns the event category for the record. Override this if you want to specify your own categories. This version returns 0.

`getEventType`(*record*)
Returns the event type for the record. Override this if you want to specify your own types. This version does a mapping using the handler's typemap attribute, which is set up in `__init__()` to a dictionary which contains mappings for `DEBUG`, `INFO`, `WARNING`, `ERROR` and `CRITICAL`. If you are using your own levels, you will either need to override this method or place a suitable dictionary in the handler's *typemap* attribute.

`getMessageID`(*record*)
Returns the message ID for the record. If you are using your own messages, you could do this by having the *msg* passed to the logger being an ID rather than a format string. Then, in here, you could use a dictionary lookup to get the message ID. This version returns 1, which is the base message ID in `win32service.pyd`.

16.8.12 SMTPHandler

The *SMTPHandler* class, located in the *logging.handlers* module, supports sending logging messages to an email address via SMTP.

`class logging.handlers.SMTPHandler`(*mailhost*, *fromaddr*, *toaddrs*, *subject*, *credentials=None*, *secure=None*, *timeout=1.0*)
Returns a new instance of the *SMTPHandler* class. The instance is initialized with the from and to addresses and subject line of the email. The *toaddrs* should be a list of strings. To specify a non-standard SMTP port, use the (host, port) tuple format for the *mailhost* argument. If you use a string, the standard SMTP port is used. If your SMTP server requires authentication, you can specify a (username, password) tuple for the *credentials* argument.

To specify the use of a secure protocol (TLS), pass in a tuple to the *secure* argument. This will only be used when authentication credentials are supplied. The tuple should be either an empty tuple, or a single-value tuple with the name of a keyfile, or a 2-value tuple with the names of the keyfile and certificate file. (This tuple is passed to the *smtplib.SMTP.starttls()* method.)

A timeout can be specified for communication with the SMTP server using the *timeout* argument.

New in version 3.3: The *timeout* argument was added.

`emit`(*record*)
Formats the record and sends it to the specified addressees.

`getSubject`(*record*)
If you want to specify a subject line which is record-dependent, override this method.

16.8.13 MemoryHandler

The *MemoryHandler* class, located in the *logging.handlers* module, supports buffering of logging records in memory, periodically flushing them to a *target* handler. Flushing occurs whenever the buffer is full, or when an event of a certain severity or greater is seen.

MemoryHandler is a subclass of the more general *BufferingHandler*, which is an abstract class. This buffers logging records in memory. Whenever each record is added to the buffer, a check is made by calling `shouldFlush()` to see if the buffer should be flushed. If it should, then `flush()` is expected to do the flushing.

`class logging.handlers.BufferingHandler`(*capacity*)
Initializes the handler with a buffer of the specified capacity.

emit(*record*)
Appends the record to the buffer. If *shouldFlush()* returns true, calls *flush()* to process the buffer.

flush()
You can override this to implement custom flushing behavior. This version just zaps the buffer to empty.

shouldFlush(*record*)
Returns true if the buffer is up to capacity. This method can be overridden to implement custom flushing strategies.

class logging.handlers.**MemoryHandler**(*capacity*, *flushLevel=ERROR*, *target=None*, *flushOnClose=True*)
Returns a new instance of the *MemoryHandler* class. The instance is initialized with a buffer size of *capacity*. If *flushLevel* is not specified, `ERROR` is used. If no *target* is specified, the target will need to be set using *setTarget()* before this handler does anything useful. If *flushOnClose* is specified as `False`, then the buffer is *not* flushed when the handler is closed. If not specified or specified as `True`, the previous behaviour of flushing the buffer will occur when the handler is closed.

Changed in version 3.6: The *flushOnClose* parameter was added.

close()
Calls *flush()*, sets the target to `None` and clears the buffer.

flush()
For a *MemoryHandler*, flushing means just sending the buffered records to the target, if there is one. The buffer is also cleared when this happens. Override if you want different behavior.

setTarget(*target*)
Sets the target handler for this handler.

shouldFlush(*record*)
Checks for buffer full or a record at the *flushLevel* or higher.

16.8.14 HTTPHandler

The *HTTPHandler* class, located in the *logging.handlers* module, supports sending logging messages to a Web server, using either `GET` or `POST` semantics.

class logging.handlers.**HTTPHandler**(*host*, *url*, *method='GET'*, *secure=False*, *credentials=None*, *context=None*)
Returns a new instance of the *HTTPHandler* class. The *host* can be of the form `host:port`, should you need to use a specific port number. If no *method* is specified, `GET` is used. If *secure* is true, a HTTPS connection will be used. The *context* parameter may be set to a *ssl.SSLContext* instance to configure the SSL settings used for the HTTPS connection. If *credentials* is specified, it should be a 2-tuple consisting of userid and password, which will be placed in a HTTP 'Authorization' header using Basic authentication. If you specify credentials, you should also specify secure=True so that your userid and password are not passed in cleartext across the wire.

Changed in version 3.5: The *context* parameter was added.

mapLogRecord(*record*)
Provides a dictionary, based on `record`, which is to be URL-encoded and sent to the web server. The default implementation just returns `record.__dict__`. This method can be overridden if e.g. only a subset of *LogRecord* is to be sent to the web server, or if more specific customization of what's sent to the server is required.

emit(*record*)
Sends the record to the Web server as a URL-encoded dictionary. The *mapLogRecord()* method is used to convert the record to the dictionary to be sent.

Note: Since preparing a record for sending it to a Web server is not the same as a generic formatting operation, using *setFormatter()* to specify a *Formatter* for a *HTTPHandler* has no effect. Instead of calling *format()*, this handler calls *mapLogRecord()* and then *urllib.parse.urlencode()* to encode the dictionary in a form suitable for sending to a Web server.

16.8.15 QueueHandler

New in version 3.2.

The *QueueHandler* class, located in the *logging.handlers* module, supports sending logging messages to a queue, such as those implemented in the *queue* or *multiprocessing* modules.

Along with the *QueueListener* class, *QueueHandler* can be used to let handlers do their work on a separate thread from the one which does the logging. This is important in Web applications and also other service applications where threads servicing clients need to respond as quickly as possible, while any potentially slow operations (such as sending an email via *SMTPHandler*) are done on a separate thread.

class logging.handlers.**QueueHandler**(*queue*)

Returns a new instance of the *QueueHandler* class. The instance is initialized with the queue to send messages to. The queue can be any queue-like object; it's used as-is by the *enqueue()* method, which needs to know how to send messages to it.

emit(*record*)

Enqueues the result of preparing the LogRecord.

prepare(*record*)

Prepares a record for queuing. The object returned by this method is enqueued.

The base implementation formats the record to merge the message and arguments, and removes unpickleable items from the record in-place.

You might want to override this method if you want to convert the record to a dict or JSON string, or send a modified copy of the record while leaving the original intact.

enqueue(*record*)

Enqueues the record on the queue using `put_nowait()`; you may want to override this if you want to use blocking behaviour, or a timeout, or a customized queue implementation.

16.8.16 QueueListener

New in version 3.2.

The *QueueListener* class, located in the *logging.handlers* module, supports receiving logging messages from a queue, such as those implemented in the *queue* or *multiprocessing* modules. The messages are received from a queue in an internal thread and passed, on the same thread, to one or more handlers for processing. While *QueueListener* is not itself a handler, it is documented here because it works hand-in-hand with *QueueHandler*.

Along with the *QueueHandler* class, *QueueListener* can be used to let handlers do their work on a separate thread from the one which does the logging. This is important in Web applications and also other service applications where threads servicing clients need to respond as quickly as possible, while any potentially slow operations (such as sending an email via *SMTPHandler*) are done on a separate thread.

class logging.handlers.**QueueListener**(*queue*, **handlers*, *respect_handler_level=False*)

Returns a new instance of the *QueueListener* class. The instance is initialized with the queue to send messages to and a list of handlers which will handle entries placed on the queue. The queue can be any queue-like object; it's passed as-is to the *dequeue()* method, which needs to know how to get messages

from it. If `respect_handler_level` is `True`, a handler's level is respected (compared with the level for the message) when deciding whether to pass messages to that handler; otherwise, the behaviour is as in previous Python versions - to always pass each message to each handler.

Changed in version 3.5: The `respect_handler_levels` argument was added.

`dequeue`(*block*)
Dequeues a record and return it, optionally blocking.

The base implementation uses `get()`. You may want to override this method if you want to use timeouts or work with custom queue implementations.

`prepare`(*record*)
Prepare a record for handling.

This implementation just returns the passed-in record. You may want to override this method if you need to do any custom marshalling or manipulation of the record before passing it to the handlers.

`handle`(*record*)
Handle a record.

This just loops through the handlers offering them the record to handle. The actual object passed to the handlers is that which is returned from *prepare()*.

`start()`
Starts the listener.

This starts up a background thread to monitor the queue for LogRecords to process.

`stop()`
Stops the listener.

This asks the thread to terminate, and then waits for it to do so. Note that if you don't call this before your application exits, there may be some records still left on the queue, which won't be processed.

`enqueue_sentinel()`
Writes a sentinel to the queue to tell the listener to quit. This implementation uses `put_nowait()`. You may want to override this method if you want to use timeouts or work with custom queue implementations.

New in version 3.3.

16.9 getpass — Portable password input

Source code: Lib/getpass.py

The *getpass* module provides two functions:

`getpass.getpass`(*prompt='Password: ', stream=None*)
Prompt the user for a password without echoing. The user is prompted using the string *prompt*, which defaults to `'Password: '`. On Unix, the prompt is written to the file-like object *stream* using the replace error handler if needed. *stream* defaults to the controlling terminal (`/dev/tty`) or if that is unavailable to `sys.stderr` (this argument is ignored on Windows).

If echo free input is unavailable getpass() falls back to printing a warning message to *stream* and reading from `sys.stdin` and issuing a *GetPassWarning*.

Note: If you call getpass from within IDLE, the input may be done in the terminal you launched IDLE from rather than the idle window itself.

exception getpass.GetPassWarning
A *UserWarning* subclass issued when password input may be echoed.

getpass.getuser()
Return the "login name" of the user.

This function checks the environment variables `LOGNAME`, `USER`, `LNAME` and `USERNAME`, in order, and returns the value of the first one which is set to a non-empty string. If none are set, the login name from the password database is returned on systems which support the *pwd* module, otherwise, an exception is raised.

In general, this function should be preferred over *os.getlogin()*.

16.10 curses — Terminal handling for character-cell displays

The *curses* module provides an interface to the curses library, the de-facto standard for portable advanced terminal handling.

While curses is most widely used in the Unix environment, versions are available for Windows, DOS, and possibly other systems as well. This extension module is designed to match the API of ncurses, an open-source curses library hosted on Linux and the BSD variants of Unix.

Note: Whenever the documentation mentions a *character* it can be specified as an integer, a one-character Unicode string or a one-byte byte string.

Whenever the documentation mentions a *character string* it can be specified as a Unicode string or a byte string.

Note: Since version 5.4, the ncurses library decides how to interpret non-ASCII data using the `nl_langinfo` function. That means that you have to call *locale.setlocale()* in the application and encode Unicode strings using one of the system's available encodings. This example uses the system's default encoding:

```
import locale
locale.setlocale(locale.LC_ALL, '')
code = locale.getpreferredencoding()
```

Then use *code* as the encoding for *str.encode()* calls.

curses-howto Tutorial material on using curses with Python, by Andrew Kuchling and Eric Raymond.

The Tools/demo/ directory in the Python source distribution contains some example programs using the curses bindings provided by this module.

16.10.1 Functions

The module *curses* defines the following exception:

exception curses.error
Exception raised when a curses library function returns an error.

Note: Whenever *x* or *y* arguments to a function or a method are optional, they default to the current cursor location. Whenever *attr* is optional, it defaults to `A_NORMAL`.

The module *curses* defines the following functions:

curses.baudrate()
Return the output speed of the terminal in bits per second. On software terminal emulators it will have a fixed high value. Included for historical reasons; in former times, it was used to write output loops for time delays and occasionally to change interfaces depending on the line speed.

curses.beep()
Emit a short attention sound.

curses.can_change_color()
Return `True` or `False`, depending on whether the programmer can change the colors displayed by the terminal.

curses.cbreak()
Enter cbreak mode. In cbreak mode (sometimes called "rare" mode) normal tty line buffering is turned off and characters are available to be read one by one. However, unlike raw mode, special characters (interrupt, quit, suspend, and flow control) retain their effects on the tty driver and calling program. Calling first *raw()* then *cbreak()* leaves the terminal in cbreak mode.

curses.color_content(*color_number***)**
Return the intensity of the red, green, and blue (RGB) components in the color *color_number*, which must be between `0` and `COLORS`. Return a 3-tuple, containing the R,G,B values for the given color, which will be between `0` (no component) and `1000` (maximum amount of component).

curses.color_pair(*color_number***)**
Return the attribute value for displaying text in the specified color. This attribute value can be combined with `A_STANDOUT`, `A_REVERSE`, and the other `A_*` attributes. *pair_number()* is the counterpart to this function.

curses.curs_set(*visibility***)**
Set the cursor state. *visibility* can be set to `0`, `1`, or `2`, for invisible, normal, or very visible. If the terminal supports the visibility requested, return the previous cursor state; otherwise raise an exception. On many terminals, the "visible" mode is an underline cursor and the "very visible" mode is a block cursor.

curses.def_prog_mode()
Save the current terminal mode as the "program" mode, the mode when the running program is using curses. (Its counterpart is the "shell" mode, for when the program is not in curses.) Subsequent calls to *reset_prog_mode()* will restore this mode.

curses.def_shell_mode()
Save the current terminal mode as the "shell" mode, the mode when the running program is not using curses. (Its counterpart is the "program" mode, when the program is using curses capabilities.) Subsequent calls to *reset_shell_mode()* will restore this mode.

curses.delay_output(*ms*)
Insert an *ms* millisecond pause in output.

curses.doupdate()
Update the physical screen. The curses library keeps two data structures, one representing the current physical screen contents and a virtual screen representing the desired next state. The *doupdate()* ground updates the physical screen to match the virtual screen.

The virtual screen may be updated by a *noutrefresh()* call after write operations such as *addstr()* have been performed on a window. The normal *refresh()* call is simply noutrefresh() followed by doupdate(); if you have to update multiple windows, you can speed performance and perhaps reduce screen flicker by issuing noutrefresh() calls on all windows, followed by a single doupdate().

curses.echo()
Enter echo mode. In echo mode, each character input is echoed to the screen as it is entered.

curses.endwin()
De-initialize the library, and return terminal to normal status.

curses.erasechar()
Return the user's current erase character as a one-byte bytes object. Under Unix operating systems this is a property of the controlling tty of the curses program, and is not set by the curses library itself.

curses.filter()
The *filter()* routine, if used, must be called before *initscr()* is called. The effect is that, during those calls, LINES is set to 1; the capabilities clear, cup, cud, cud1, cuu1, cuu, vpa are disabled; and the home string is set to the value of cr. The effect is that the cursor is confined to the current line, and so are screen updates. This may be used for enabling character-at-a-time line editing without touching the rest of the screen.

curses.flash()
Flash the screen. That is, change it to reverse-video and then change it back in a short interval. Some people prefer such as 'visible bell' to the audible attention signal produced by *beep()*.

curses.flushinp()
Flush all input buffers. This throws away any typeahead that has been typed by the user and has not yet been processed by the program.

curses.getmouse()
After *getch()* returns KEY_MOUSE to signal a mouse event, this method should be call to retrieve the queued mouse event, represented as a 5-tuple (id, x, y, z, bstate). *id* is an ID value used to distinguish multiple devices, and *x*, *y*, *z* are the event's coordinates. (*z* is currently unused.) *bstate* is an integer value whose bits will be set to indicate the type of event, and will be the bitwise OR of one or more of the following constants, where *n* is the button number from 1 to 4: BUTTONn_PRESSED, BUTTONn_RELEASED, BUTTONn_CLICKED, BUTTONn_DOUBLE_CLICKED, BUTTONn_TRIPLE_CLICKED, BUTTON_SHIFT, BUTTON_CTRL, BUTTON_ALT.

curses.getsyx()
Return the current coordinates of the virtual screen cursor as a tuple (y, x). If *leaveok* is currently True, then return (-1, -1).

curses.getwin(*file*)
Read window related data stored in the file by an earlier putwin() call. The routine then creates and initializes a new window using that data, returning the new window object.

curses.has_colors()
Return True if the terminal can display colors; otherwise, return False.

curses.has_ic()
Return True if the terminal has insert- and delete-character capabilities. This function is included for historical reasons only, as all modern software terminal emulators have such capabilities.

curses.**has_il**()
Return True if the terminal has insert- and delete-line capabilities, or can simulate them using scrolling regions. This function is included for historical reasons only, as all modern software terminal emulators have such capabilities.

curses.**has_key**(*ch*)
Take a key value *ch*, and return True if the current terminal type recognizes a key with that value.

curses.**halfdelay**(*tenths*)
Used for half-delay mode, which is similar to cbreak mode in that characters typed by the user are immediately available to the program. However, after blocking for *tenths* tenths of seconds, raise an exception if nothing has been typed. The value of *tenths* must be a number between 1 and 255. Use *nocbreak()* to leave half-delay mode.

curses.**init_color**(*color_number*, *r*, *g*, *b*)
Change the definition of a color, taking the number of the color to be changed followed by three RGB values (for the amounts of red, green, and blue components). The value of *color_number* must be between 0 and COLORS. Each of *r*, *g*, *b*, must be a value between 0 and 1000. When *init_color()* is used, all occurrences of that color on the screen immediately change to the new definition. This function is a no-op on most terminals; it is active only if *can_change_color()* returns True.

curses.**init_pair**(*pair_number*, *fg*, *bg*)
Change the definition of a color-pair. It takes three arguments: the number of the color-pair to be changed, the foreground color number, and the background color number. The value of *pair_number* must be between 1 and COLOR_PAIRS - 1 (the 0 color pair is wired to white on black and cannot be changed). The value of *fg* and *bg* arguments must be between 0 and COLORS. If the color-pair was previously initialized, the screen is refreshed and all occurrences of that color-pair are changed to the new definition.

curses.**initscr**()
Initialize the library. Return a *window* object which represents the whole screen.

Note: If there is an error opening the terminal, the underlying curses library may cause the interpreter to exit.

---

curses.**is_term_resized**(*nlines*, *ncols*)
Return True if *resize_term()* would modify the window structure, False otherwise.

curses.**isendwin**()
Return True if *endwin()* has been called (that is, the curses library has been deinitialized).

curses.**keyname**(*k*)
Return the name of the key numbered *k* as a bytes object. The name of a key generating printable ASCII character is the key's character. The name of a control-key combination is a two-byte bytes object consisting of a caret (b'^') followed by the corresponding printable ASCII character. The name of an alt-key combination (128–255) is a bytes object consisting of the prefix b'M-' followed by the name of the corresponding ASCII character.

curses.**killchar**()
Return the user's current line kill character as a one-byte bytes object. Under Unix operating systems this is a property of the controlling tty of the curses program, and is not set by the curses library itself.

curses.**longname**()
Return a bytes object containing the terminfo long name field describing the current terminal. The maximum length of a verbose description is 128 characters. It is defined only after the call to *initscr()*.

curses.**meta**(*flag*)
If *flag* is True, allow 8-bit characters to be input. If *flag* is False, allow only 7-bit chars.

curses.**mouseinterval**(*interval*)
Set the maximum time in milliseconds that can elapse between press and release events in order for them to be recognized as a click, and return the previous interval value. The default value is 200 msec, or one fifth of a second.

curses.**mousemask**(*mousemask*)
Set the mouse events to be reported, and return a tuple `(availmask, oldmask)`. *availmask* indicates which of the specified mouse events can be reported; on complete failure it returns `0`. *oldmask* is the previous value of the given window's mouse event mask. If this function is never called, no mouse events are ever reported.

curses.**napms**(*ms*)
Sleep for *ms* milliseconds.

curses.**newpad**(*nlines*, *ncols*)
Create and return a pointer to a new pad data structure with the given number of lines and columns. Return a pad as a window object.

A pad is like a window, except that it is not restricted by the screen size, and is not necessarily associated with a particular part of the screen. Pads can be used when a large window is needed, and only a part of the window will be on the screen at one time. Automatic refreshes of pads (such as from scrolling or echoing of input) do not occur. The *refresh()* and *noutrefresh()* methods of a pad require 6 arguments to specify the part of the pad to be displayed and the location on the screen to be used for the display. The arguments are *pminrow*, *pmincol*, *sminrow*, *smincol*, *smaxrow*, *smaxcol*; the *p* arguments refer to the upper left corner of the pad region to be displayed and the *s* arguments define a clipping box on the screen within which the pad region is to be displayed.

curses.**newwin**(*nlines*, *ncols*)
curses.**newwin**(*nlines*, *ncols*, *begin_y*, *begin_x*)
Return a new *window*, whose left-upper corner is at `(begin_y, begin_x)`, and whose height/width is *nlines*/*ncols*.

By default, the window will extend from the specified position to the lower right corner of the screen.

curses.**nl**()
Enter newline mode. This mode translates the return key into newline on input, and translates newline into return and line-feed on output. Newline mode is initially on.

curses.**nocbreak**()
Leave cbreak mode. Return to normal "cooked" mode with line buffering.

curses.**noecho**()
Leave echo mode. Echoing of input characters is turned off.

curses.**nonl**()
Leave newline mode. Disable translation of return into newline on input, and disable low-level translation of newline into newline/return on output (but this does not change the behavior of `addch('\n')`, which always does the equivalent of return and line feed on the virtual screen). With translation off, curses can sometimes speed up vertical motion a little; also, it will be able to detect the return key on input.

curses.**noqiflush**()
When the `noqiflush()` routine is used, normal flush of input and output queues associated with the `INTR`, `QUIT` and `SUSP` characters will not be done. You may want to call `noqiflush()` in a signal handler if you want output to continue as though the interrupt had not occurred, after the handler exits.

curses.**noraw**()
Leave raw mode. Return to normal "cooked" mode with line buffering.

curses.**pair_content**(*pair_number*)
Return a tuple `(fg, bg)` containing the colors for the requested color pair. The value of *pair_number* must be between `1` and `COLOR_PAIRS - 1`.

curses.**pair_number**(*attr*)
Return the number of the color-pair set by the attribute value *attr*. *color_pair()* is the counterpart to this function.

curses.**putp**(*str*)
Equivalent to `tputs(str, 1, putchar)`; emit the value of a specified terminfo capability for the current terminal. Note that the output of *putp()* always goes to standard output.

curses.**qiflush**([*flag*])
If *flag* is `False`, the effect is the same as calling *noqiflush()*. If *flag* is `True`, or no argument is provided, the queues will be flushed when these control characters are read.

curses.**raw**()
Enter raw mode. In raw mode, normal line buffering and processing of interrupt, quit, suspend, and flow control keys are turned off; characters are presented to curses input functions one by one.

curses.**reset_prog_mode**()
Restore the terminal to "program" mode, as previously saved by *def_prog_mode()*.

curses.**reset_shell_mode**()
Restore the terminal to "shell" mode, as previously saved by *def_shell_mode()*.

curses.**resetty**()
Restore the state of the terminal modes to what it was at the last call to *savetty()*.

curses.**resize_term**(*nlines*, *ncols*)
Backend function used by *resizeterm()*, performing most of the work; when resizing the windows, *resize_term()* blank-fills the areas that are extended. The calling application should fill in these areas with appropriate data. The `resize_term()` function attempts to resize all windows. However, due to the calling convention of pads, it is not possible to resize these without additional interaction with the application.

curses.**resizeterm**(*nlines*, *ncols*)
Resize the standard and current windows to the specified dimensions, and adjusts other bookkeeping data used by the curses library that record the window dimensions (in particular the SIGWINCH handler).

curses.**savetty**()
Save the current state of the terminal modes in a buffer, usable by *resetty()*.

curses.**setsyx**(*y*, *x*)
Set the virtual screen cursor to *y*, *x*. If *y* and *x* are both `-1`, then *leaveok* is set `True`.

curses.**setupterm**(*term=None*, *fd=-1*)
Initialize the terminal. *term* is a string giving the terminal name, or `None`; if omitted or `None`, the value of the `TERM` environment variable will be used. *fd* is the file descriptor to which any initialization sequences will be sent; if not supplied or `-1`, the file descriptor for `sys.stdout` will be used.

curses.**start_color**()
Must be called if the programmer wants to use colors, and before any other color manipulation routine is called. It is good practice to call this routine right after *initscr()*.

start_color() initializes eight basic colors (black, red, green, yellow, blue, magenta, cyan, and white), and two global variables in the *curses* module, `COLORS` and `COLOR_PAIRS`, containing the maximum number of colors and color-pairs the terminal can support. It also restores the colors on the terminal to the values they had when the terminal was just turned on.

curses.**termattrs**()
Return a logical OR of all video attributes supported by the terminal. This information is useful when a curses program needs complete control over the appearance of the screen.

curses.**termname**()
Return the value of the environment variable TERM, as a bytes object, truncated to 14 characters.

curses.**tigetflag**(*capname*)
Return the value of the Boolean capability corresponding to the terminfo capability name *capname* as an integer. Return the value -1 if *capname* is not a Boolean capability, or 0 if it is canceled or absent from the terminal description.

curses.**tigetnum**(*capname*)
Return the value of the numeric capability corresponding to the terminfo capability name *capname* as an integer. Return the value -2 if *capname* is not a numeric capability, or -1 if it is canceled or absent from the terminal description.

curses.**tigetstr**(*capname*)
Return the value of the string capability corresponding to the terminfo capability name *capname* as a bytes object. Return None if *capname* is not a terminfo "string capability", or is canceled or absent from the terminal description.

curses.**tparm**(*str*[, *...*])
Instantiate the bytes object *str* with the supplied parameters, where *str* should be a parameterized string obtained from the terminfo database. E.g. `tparm(tigetstr("cup"), 5, 3)` could result in `b'\033[6;4H'`, the exact result depending on terminal type.

curses.**typeahead**(*fd*)
Specify that the file descriptor *fd* be used for typeahead checking. If *fd* is -1, then no typeahead checking is done.

The curses library does "line-breakout optimization" by looking for typeahead periodically while updating the screen. If input is found, and it is coming from a tty, the current update is postponed until refresh or doupdate is called again, allowing faster response to commands typed in advance. This function allows specifying a different file descriptor for typeahead checking.

curses.**unctrl**(*ch*)
Return a bytes object which is a printable representation of the character *ch*. Control characters are represented as a caret followed by the character, for example as `b'^C'`. Printing characters are left as they are.

curses.**ungetch**(*ch*)
Push *ch* so the next *getch()* will return it.

Note: Only one *ch* can be pushed before `getch()` is called.

---

curses.**update_lines_cols**()
Update LINES and COLS. Useful for detecting manual screen resize.

New in version 3.5.

curses.**unget_wch**(*ch*)
Push *ch* so the next *get_wch()* will return it.

Note: Only one *ch* can be pushed before `get_wch()` is called.

New in version 3.3.

curses.**ungetmouse**(*id*, *x*, *y*, *z*, *bstate*)
Push a KEY_MOUSE event onto the input queue, associating the given state data with it.

curses.**use_env**(*flag*)
If used, this function should be called before *initscr()* or newterm are called. When *flag* is False, the values of lines and columns specified in the terminfo database will be used, even if environment variables LINES and COLUMNS (used by default) are set, or if curses is running in a window (in which case default behavior would be to use the window size if LINES and COLUMNS are not set).

curses.**use_default_colors**()
Allow use of default values for colors on terminals supporting this feature. Use this to support transparency in your application. The default color is assigned to the color number -1. After calling this function, init_pair(x, curses.COLOR_RED, -1) initializes, for instance, color pair *x* to a red foreground color on the default background.

curses.**wrapper**(*func*, ...)
Initialize curses and call another callable object, *func*, which should be the rest of your curses-using application. If the application raises an exception, this function will restore the terminal to a sane state before re-raising the exception and generating a traceback. The callable object *func* is then passed the main window 'stdscr' as its first argument, followed by any other arguments passed to wrapper(). Before calling *func*, wrapper() turns on cbreak mode, turns off echo, enables the terminal keypad, and initializes colors if the terminal has color support. On exit (whether normally or by exception) it restores cooked mode, turns on echo, and disables the terminal keypad.

16.10.2 Window Objects

Window objects, as returned by *initscr()* and *newwin()* above, have the following methods and attributes:

window.**addch**(*ch*[, *attr*])
window.**addch**(*y*, *x*, *ch*[, *attr*])
Paint character *ch* at (y, x) with attributes *attr*, overwriting any character previously painter at that location. By default, the character position and attributes are the current settings for the window object.

Note: Writing outside the window, subwindow, or pad raises a *curses.error*. Attempting to write to the lower right corner of a window, subwindow, or pad will cause an exception to be raised after the character is printed.

---

window.**addnstr**(*str*, *n*[, *attr*])
window.**addnstr**(*y*, *x*, *str*, *n*[, *attr*])
Paint at most *n* characters of the character string *str* at (y, x) with attributes *attr*, overwriting anything previously on the display.

window.**addstr**(*str*[, *attr*])
window.**addstr**(*y*, *x*, *str*[, *attr*])
Paint the character string *str* at (y, x) with attributes *attr*, overwriting anything previously on the display.

Note: Writing outside the window, subwindow, or pad raises *curses.error*. Attempting to write to the lower right corner of a window, subwindow, or pad will cause an exception to be raised after the string is printed.

`window.attroff(`*attr*`)`
Remove attribute *attr* from the "background" set applied to all writes to the current window.

`window.attron(`*attr*`)`
Add attribute *attr* from the "background" set applied to all writes to the current window.

`window.attrset(`*attr*`)`
Set the "background" set of attributes to *attr*. This set is initially `0` (no attributes).

`window.bkgd(`*ch*[, *attr*]`)`
Set the background property of the window to the character *ch*, with attributes *attr*. The change is then applied to every character position in that window:

- The attribute of every character in the window is changed to the new background attribute.
- Wherever the former background character appears, it is changed to the new background character.

`window.bkgdset(`*ch*[, *attr*]`)`
Set the window's background. A window's background consists of a character and any combination of attributes. The attribute part of the background is combined (OR'ed) with all non-blank characters that are written into the window. Both the character and attribute parts of the background are combined with the blank characters. The background becomes a property of the character and moves with the character through any scrolling and insert/delete line/character operations.

`window.border(`[*ls*[, *rs*[, *ts*[, *bs*[, *tl*[, *tr*[, *bl*[, *br*]]]]]]]]`)`
Draw a border around the edges of the window. Each parameter specifies the character to use for a specific part of the border; see the table below for more details.

Note: A `0` value for any parameter will cause the default character to be used for that parameter. Keyword parameters can *not* be used. The defaults are listed in this table:

Parameter	Description	Default value
ls	Left side	`ACS_VLINE`
rs	Right side	`ACS_VLINE`
ts	Top	`ACS_HLINE`
bs	Bottom	`ACS_HLINE`
tl	Upper-left corner	`ACS_ULCORNER`
tr	Upper-right corner	`ACS_URCORNER`
bl	Bottom-left corner	`ACS_LLCORNER`
br	Bottom-right corner	`ACS_LRCORNER`

`window.box(`[*vertch*, *horch*]`)`
Similar to *border()*, but both *ls* and *rs* are *vertch* and both *ts* and *bs* are *horch*. The default corner characters are always used by this function.

`window.chgat(`*attr*`)`
`window.chgat(`*num*, *attr*`)`
`window.chgat(`*y*, *x*, *attr*`)`
`window.chgat(`*y*, *x*, *num*, *attr*`)`
Set the attributes of *num* characters at the current cursor position, or at position `(y, x)` if supplied. If *num* is not given or is `-1`, the attribute will be set on all the characters to the end of the line. This function moves cursor to position `(y, x)` if supplied. The changed line will be touched using the *touchline()* method so that the contents will be redisplayed by the next window refresh.

`window.clear()`
Like *erase()*, but also cause the whole window to be repainted upon next call to *refresh()*.

window.**clearok**(*flag*)
If *flag* is `True`, the next call to *refresh()* will clear the window completely.

window.**clrtobot**()
Erase from cursor to the end of the window: all lines below the cursor are deleted, and then the equivalent of *clrtoeol()* is performed.

window.**clrtoeol**()
Erase from cursor to the end of the line.

window.**cursyncup**()
Update the current cursor position of all the ancestors of the window to reflect the current cursor position of the window.

window.**delch**([*y*, *x*])
Delete any character at `(y, x)`.

window.**deleteln**()
Delete the line under the cursor. All following lines are moved up by one line.

window.**derwin**(*begin_y*, *begin_x*)
window.**derwin**(*nlines*, *ncols*, *begin_y*, *begin_x*)
An abbreviation for "derive window", *derwin()* is the same as calling *subwin()*, except that *begin_y* and *begin_x* are relative to the origin of the window, rather than relative to the entire screen. Return a window object for the derived window.

window.**echochar**(*ch*[, *attr*])
Add character *ch* with attribute *attr*, and immediately call *refresh()* on the window.

window.**enclose**(*y*, *x*)
Test whether the given pair of screen-relative character-cell coordinates are enclosed by the given window, returning `True` or `False`. It is useful for determining what subset of the screen windows enclose the location of a mouse event.

window.**encoding**
Encoding used to encode method arguments (Unicode strings and characters). The encoding attribute is inherited from the parent window when a subwindow is created, for example with *window.subwin()*. By default, the locale encoding is used (see *locale.getpreferredencoding()*).

New in version 3.3.

window.**erase**()
Clear the window.

window.**getbegyx**()
Return a tuple `(y, x)` of co-ordinates of upper-left corner.

window.**getbkgd**()
Return the given window's current background character/attribute pair.

window.**getch**([*y*, *x*])
Get a character. Note that the integer returned does *not* have to be in ASCII range: function keys, keypad keys and so on are represented by numbers higher than 255. In no-delay mode, return `-1` if there is no input, otherwise wait until a key is pressed.

window.**get_wch**([*y*, *x*])
Get a wide character. Return a character for most keys, or an integer for function keys, keypad keys, and other special keys. In no-delay mode, raise an exception if there is no input.

New in version 3.3.

window.**getkey**([*y*, *x*])
Get a character, returning a string instead of an integer, as *getch()* does. Function keys, keypad keys

and other special keys return a multibyte string containing the key name. In no-delay mode, raise an exception if there is no input.

window.getmaxyx()
Return a tuple `(y, x)` of the height and width of the window.

window.getparyx()
Return the beginning coordinates of this window relative to its parent window as a tuple `(y, x)`. Return `(-1, -1)` if this window has no parent.

window.getstr()
window.getstr(*n***)**
window.getstr(*y*, *x***)**
window.getstr(*y*, *x*, *n***)**
Read a bytes object from the user, with primitive line editing capacity.

window.getyx()
Return a tuple `(y, x)` of current cursor position relative to the window's upper-left corner.

window.hline(*ch*, *n***)**
window.hline(*y*, *x*, *ch*, *n***)**
Display a horizontal line starting at `(y, x)` with length *n* consisting of the character *ch*.

window.idcok(*flag***)**
If *flag* is `False`, curses no longer considers using the hardware insert/delete character feature of the terminal; if *flag* is `True`, use of character insertion and deletion is enabled. When curses is first initialized, use of character insert/delete is enabled by default.

window.idlok(*flag***)**
If *flag* is `True`, *curses* will try and use hardware line editing facilities. Otherwise, line insertion/deletion are disabled.

window.immedok(*flag***)**
If *flag* is `True`, any change in the window image automatically causes the window to be refreshed; you no longer have to call *refresh()* yourself. However, it may degrade performance considerably, due to repeated calls to wrefresh. This option is disabled by default.

window.inch([*y*, *x*]**)**
Return the character at the given position in the window. The bottom 8 bits are the character proper, and upper bits are the attributes.

window.insch(*ch*[, *attr*]**)**
window.insch(*y*, *x*, *ch*[, *attr*]**)**
Paint character *ch* at `(y, x)` with attributes *attr*, moving the line from position *x* right by one character.

window.insdelln(*nlines***)**
Insert *nlines* lines into the specified window above the current line. The *nlines* bottom lines are lost. For negative *nlines*, delete *nlines* lines starting with the one under the cursor, and move the remaining lines up. The bottom *nlines* lines are cleared. The current cursor position remains the same.

window.insertln()
Insert a blank line under the cursor. All following lines are moved down by one line.

window.insnstr(*str*, *n*[, *attr*]**)**
window.insnstr(*y*, *x*, *str*, *n*[, *attr*]**)**
Insert a character string (as many characters as will fit on the line) before the character under the cursor, up to *n* characters. If *n* is zero or negative, the entire string is inserted. All characters to the right of the cursor are shifted right, with the rightmost characters on the line being lost. The cursor position does not change (after moving to *y*, *x*, if specified).

window.insstr(*str*[, *attr*]**)**

window.insstr(*y*, *x*, *str*[, *attr*])
Insert a character string (as many characters as will fit on the line) before the character under the cursor. All characters to the right of the cursor are shifted right, with the rightmost characters on the line being lost. The cursor position does not change (after moving to *y*, *x*, if specified).

window.instr([*n*])
window.instr(*y*, *x*[, *n*])
Return a bytes object of characters, extracted from the window starting at the current cursor position, or at *y*, *x* if specified. Attributes are stripped from the characters. If *n* is specified, *instr()* returns a string at most *n* characters long (exclusive of the trailing NUL).

window.is_linetouched(*line*)
Return `True` if the specified line was modified since the last call to *refresh()*; otherwise return `False`. Raise a *curses.error* exception if *line* is not valid for the given window.

window.is_wintouched()
Return `True` if the specified window was modified since the last call to *refresh()*; otherwise return `False`.

window.keypad(*flag*)
If *flag* is `True`, escape sequences generated by some keys (keypad, function keys) will be interpreted by *curses*. If *flag* is `False`, escape sequences will be left as is in the input stream.

window.leaveok(*flag*)
If *flag* is `True`, cursor is left where it is on update, instead of being at "cursor position." This reduces cursor movement where possible. If possible the cursor will be made invisible.

If *flag* is `False`, cursor will always be at "cursor position" after an update.

window.move(*new_y*, *new_x*)
Move cursor to `(new_y, new_x)`.

window.mvderwin(*y*, *x*)
Move the window inside its parent window. The screen-relative parameters of the window are not changed. This routine is used to display different parts of the parent window at the same physical position on the screen.

window.mvwin(*new_y*, *new_x*)
Move the window so its upper-left corner is at `(new_y, new_x)`.

window.nodelay(*flag*)
If *flag* is `True`, *getch()* will be non-blocking.

window.notimeout(*flag*)
If *flag* is `True`, escape sequences will not be timed out.

If *flag* is `False`, after a few milliseconds, an escape sequence will not be interpreted, and will be left in the input stream as is.

window.noutrefresh()
Mark for refresh but wait. This function updates the data structure representing the desired state of the window, but does not force an update of the physical screen. To accomplish that, call *doupdate()*.

window.overlay(*destwin*[, *sminrow*, *smincol*, *dminrow*, *dmincol*, *dmaxrow*, *dmaxcol*])
Overlay the window on top of *destwin*. The windows need not be the same size, only the overlapping region is copied. This copy is non-destructive, which means that the current background character does not overwrite the old contents of *destwin*.

To get fine-grained control over the copied region, the second form of *overlay()* can be used. *sminrow* and *smincol* are the upper-left coordinates of the source window, and the other variables mark a rectangle in the destination window.

window.overwrite(*destwin*[, *sminrow*, *smincol*, *dminrow*, *dmincol*, *dmaxrow*, *dmaxcol*])
Overwrite the window on top of *destwin*. The windows need not be the same size, in which case only the overlapping region is copied. This copy is destructive, which means that the current background character overwrites the old contents of *destwin*.

To get fine-grained control over the copied region, the second form of *overwrite()* can be used. *sminrow* and *smincol* are the upper-left coordinates of the source window, the other variables mark a rectangle in the destination window.

window.putwin(*file*)
Write all data associated with the window into the provided file object. This information can be later retrieved using the *getwin()* function.

window.redrawln(*beg*, *num*)
Indicate that the *num* screen lines, starting at line *beg*, are corrupted and should be completely redrawn on the next *refresh()* call.

window.redrawwin()
Touch the entire window, causing it to be completely redrawn on the next *refresh()* call.

window.refresh([*pminrow*, *pmincol*, *sminrow*, *smincol*, *smaxrow*, *smaxcol*])
Update the display immediately (sync actual screen with previous drawing/deleting methods).

The 6 optional arguments can only be specified when the window is a pad created with *newpad()*. The additional parameters are needed to indicate what part of the pad and screen are involved. *pminrow* and *pmincol* specify the upper left-hand corner of the rectangle to be displayed in the pad. *sminrow*, *smincol*, *smaxrow*, and *smaxcol* specify the edges of the rectangle to be displayed on the screen. The lower right-hand corner of the rectangle to be displayed in the pad is calculated from the screen coordinates, since the rectangles must be the same size. Both rectangles must be entirely contained within their respective structures. Negative values of *pminrow*, *pmincol*, *sminrow*, or *smincol* are treated as if they were zero.

window.resize(*nlines*, *ncols*)
Reallocate storage for a curses window to adjust its dimensions to the specified values. If either dimension is larger than the current values, the window's data is filled with blanks that have the current background rendition (as set by *bkgdset()*) merged into them.

window.scroll([*lines=1*])
Scroll the screen or scrolling region upward by *lines* lines.

window.scrollok(*flag*)
Control what happens when the cursor of a window is moved off the edge of the window or scrolling region, either as a result of a newline action on the bottom line, or typing the last character of the last line. If *flag* is `False`, the cursor is left on the bottom line. If *flag* is `True`, the window is scrolled up one line. Note that in order to get the physical scrolling effect on the terminal, it is also necessary to call *idlok()*.

window.setscrreg(*top*, *bottom*)
Set the scrolling region from line *top* to line *bottom*. All scrolling actions will take place in this region.

window.standend()
Turn off the standout attribute. On some terminals this has the side effect of turning off all attributes.

window.standout()
Turn on attribute *A_STANDOUT*.

window.subpad(*begin_y*, *begin_x*)
window.subpad(*nlines*, *ncols*, *begin_y*, *begin_x*)
Return a sub-window, whose upper-left corner is at `(begin_y, begin_x)`, and whose width/height is *ncols*/*nlines*.

window.subwin(*begin_y*, *begin_x*)

window.subwin(*nlines*, *ncols*, *begin_y*, *begin_x*)
Return a sub-window, whose upper-left corner is at `(begin_y, begin_x)`, and whose width/height is *ncols*/*nlines*.

By default, the sub-window will extend from the specified position to the lower right corner of the window.

window.syncdown()
Touch each location in the window that has been touched in any of its ancestor windows. This routine is called by *refresh()*, so it should almost never be necessary to call it manually.

window.syncok(*flag*)
If *flag* is `True`, then *syncup()* is called automatically whenever there is a change in the window.

window.syncup()
Touch all locations in ancestors of the window that have been changed in the window.

window.timeout(*delay*)
Set blocking or non-blocking read behavior for the window. If *delay* is negative, blocking read is used (which will wait indefinitely for input). If *delay* is zero, then non-blocking read is used, and *getch()* will return `-1` if no input is waiting. If *delay* is positive, then *getch()* will block for *delay* milliseconds, and return `-1` if there is still no input at the end of that time.

window.touchline(*start*, *count*[, *changed*])
Pretend *count* lines have been changed, starting with line *start*. If *changed* is supplied, it specifies whether the affected lines are marked as having been changed (*changed*=`True`) or unchanged (*changed*=`False`).

window.touchwin()
Pretend the whole window has been changed, for purposes of drawing optimizations.

window.untouchwin()
Mark all lines in the window as unchanged since the last call to *refresh()*.

window.vline(*ch*, *n*)
window.vline(*y*, *x*, *ch*, *n*)
Display a vertical line starting at `(y, x)` with length *n* consisting of the character *ch*.

16.10.3 Constants

The *curses* module defines the following data members:

curses.ERR
Some curses routines that return an integer, such as `getch()`, return *ERR* upon failure.

curses.OK
Some curses routines that return an integer, such as *napms()*, return *OK* upon success.

curses.version
A bytes object representing the current version of the module. Also available as `__version__`.

Some constants are available to specify character cell attributes. The exact constants available are system dependent.

Attribute	Meaning
A_ALTCHARSET	Alternate character set mode
A_BLINK	Blink mode
A_BOLD	Bold mode
A_DIM	Dim mode
A_INVIS	Invisible or blank mode
A_ITALIC	Italic mode
A_NORMAL	Normal attribute
A_PROTECT	Protected mode
A_REVERSE	Reverse background and foreground colors
A_STANDOUT	Standout mode
A_UNDERLINE	Underline mode
A_HORIZONTAL	Horizontal highlight
A_LEFT	Left highlight
A_LOW	Low highlight
A_RIGHT	Right highlight
A_TOP	Top highlight
A_VERTICAL	Vertical highlight
A_CHARTEXT	Bit-mask to extract a character

New in version 3.7: A_ITALIC was added.

Several constants are available to extract corresponding attributes returned by some methods.

Bit-mask	Meaning
A_ATTRIBUTES	Bit-mask to extract attributes
A_CHARTEXT	Bit-mask to extract a character
A_COLOR	Bit-mask to extract color-pair field information

Keys are referred to by integer constants with names starting with KEY_. The exact keycaps available are system dependent.

Key constant	Key
KEY_MIN	Minimum key value
KEY_BREAK	Break key (unreliable)
KEY_DOWN	Down-arrow
KEY_UP	Up-arrow
KEY_LEFT	Left-arrow
KEY_RIGHT	Right-arrow
KEY_HOME	Home key (upward+left arrow)
KEY_BACKSPACE	Backspace (unreliable)
KEY_F0	Function keys. Up to 64 function keys are supported.
KEY_Fn	Value of function key n
KEY_DL	Delete line
KEY_IL	Insert line
KEY_DC	Delete character
KEY_IC	Insert char or enter insert mode
KEY_EIC	Exit insert char mode
KEY_CLEAR	Clear screen
KEY_EOS	Clear to end of screen
KEY_EOL	Clear to end of line

Continued on next page

Table 1 – continued from previous page

Key constant	Key
KEY_SF	Scroll 1 line forward
KEY_SR	Scroll 1 line backward (reverse)
KEY_NPAGE	Next page
KEY_PPAGE	Previous page
KEY_STAB	Set tab
KEY_CTAB	Clear tab
KEY_CATAB	Clear all tabs
KEY_ENTER	Enter or send (unreliable)
KEY_SRESET	Soft (partial) reset (unreliable)
KEY_RESET	Reset or hard reset (unreliable)
KEY_PRINT	Print
KEY_LL	Home down or bottom (lower left)
KEY_A1	Upper left of keypad
KEY_A3	Upper right of keypad
KEY_B2	Center of keypad
KEY_C1	Lower left of keypad
KEY_C3	Lower right of keypad
KEY_BTAB	Back tab
KEY_BEG	Beg (beginning)
KEY_CANCEL	Cancel
KEY_CLOSE	Close
KEY_COMMAND	Cmd (command)
KEY_COPY	Copy
KEY_CREATE	Create
KEY_END	End
KEY_EXIT	Exit
KEY_FIND	Find
KEY_HELP	Help
KEY_MARK	Mark
KEY_MESSAGE	Message
KEY_MOVE	Move
KEY_NEXT	Next
KEY_OPEN	Open
KEY_OPTIONS	Options
KEY_PREVIOUS	Prev (previous)
KEY_REDO	Redo
KEY_REFERENCE	Ref (reference)
KEY_REFRESH	Refresh
KEY_REPLACE	Replace
KEY_RESTART	Restart
KEY_RESUME	Resume
KEY_SAVE	Save
KEY_SBEG	Shifted Beg (beginning)
KEY_SCANCEL	Shifted Cancel
KEY_SCOMMAND	Shifted Command
KEY_SCOPY	Shifted Copy
KEY_SCREATE	Shifted Create
KEY_SDC	Shifted Delete char
KEY_SDL	Shifted Delete line

Continued on next page

Table 1 – continued from previous page

Key constant	Key
KEY_SELECT	Select
KEY_SEND	Shifted End
KEY_SEOL	Shifted Clear line
KEY_SEXIT	Shifted Exit
KEY_SFIND	Shifted Find
KEY_SHELP	Shifted Help
KEY_SHOME	Shifted Home
KEY_SIC	Shifted Input
KEY_SLEFT	Shifted Left arrow
KEY_SMESSAGE	Shifted Message
KEY_SMOVE	Shifted Move
KEY_SNEXT	Shifted Next
KEY_SOPTIONS	Shifted Options
KEY_SPREVIOUS	Shifted Prev
KEY_SPRINT	Shifted Print
KEY_SREDO	Shifted Redo
KEY_SREPLACE	Shifted Replace
KEY_SRIGHT	Shifted Right arrow
KEY_SRSUME	Shifted Resume
KEY_SSAVE	Shifted Save
KEY_SSUSPEND	Shifted Suspend
KEY_SUNDO	Shifted Undo
KEY_SUSPEND	Suspend
KEY_UNDO	Undo
KEY_MOUSE	Mouse event has occurred
KEY_RESIZE	Terminal resize event
KEY_MAX	Maximum key value

On VT100s and their software emulations, such as X terminal emulators, there are normally at least four function keys (KEY_F1, KEY_F2, KEY_F3, KEY_F4) available, and the arrow keys mapped to KEY_UP, KEY_DOWN, KEY_LEFT and KEY_RIGHT in the obvious way. If your machine has a PC keyboard, it is safe to expect arrow keys and twelve function keys (older PC keyboards may have only ten function keys); also, the following keypad mappings are standard:

Keycap	Constant
Insert	KEY_IC
Delete	KEY_DC
Home	KEY_HOME
End	KEY_END
Page Up	KEY_PPAGE
Page Down	KEY_NPAGE

The following table lists characters from the alternate character set. These are inherited from the VT100 terminal, and will generally be available on software emulations such as X terminals. When there is no graphic available, curses falls back on a crude printable ASCII approximation.

Note: These are available only after *initscr()* has been called.

ACS code	Meaning
ACS_BBSS	alternate name for upper right corner
ACS_BLOCK	solid square block
ACS_BOARD	board of squares
ACS_BSBS	alternate name for horizontal line
ACS_BSSB	alternate name for upper left corner
ACS_BSSS	alternate name for top tee
ACS_BTEE	bottom tee
ACS_BULLET	bullet
ACS_CKBOARD	checker board (stipple)
ACS_DARROW	arrow pointing down
ACS_DEGREE	degree symbol
ACS_DIAMOND	diamond
ACS_GEQUAL	greater-than-or-equal-to
ACS_HLINE	horizontal line
ACS_LANTERN	lantern symbol
ACS_LARROW	left arrow
ACS_LEQUAL	less-than-or-equal-to
ACS_LLCORNER	lower left-hand corner
ACS_LRCORNER	lower right-hand corner
ACS_LTEE	left tee
ACS_NEQUAL	not-equal sign
ACS_PI	letter pi
ACS_PLMINUS	plus-or-minus sign
ACS_PLUS	big plus sign
ACS_RARROW	right arrow
ACS_RTEE	right tee
ACS_S1	scan line 1
ACS_S3	scan line 3
ACS_S7	scan line 7
ACS_S9	scan line 9
ACS_SBBS	alternate name for lower right corner
ACS_SBSB	alternate name for vertical line
ACS_SBSS	alternate name for right tee
ACS_SSBB	alternate name for lower left corner
ACS_SSBS	alternate name for bottom tee
ACS_SSSB	alternate name for left tee
ACS_SSSS	alternate name for crossover or big plus
ACS_STERLING	pound sterling
ACS_TTEE	top tee
ACS_UARROW	up arrow
ACS_ULCORNER	upper left corner
ACS_URCORNER	upper right corner
ACS_VLINE	vertical line

The following table lists the predefined colors:

Constant	Color
COLOR_BLACK	Black
COLOR_BLUE	Blue
COLOR_CYAN	Cyan (light greenish blue)
COLOR_GREEN	Green
COLOR_MAGENTA	Magenta (purplish red)
COLOR_RED	Red
COLOR_WHITE	White
COLOR_YELLOW	Yellow

16.11 curses.textpad — Text input widget for curses programs

The *curses.textpad* module provides a *Textbox* class that handles elementary text editing in a curses window, supporting a set of keybindings resembling those of Emacs (thus, also of Netscape Navigator, BBedit 6.x, FrameMaker, and many other programs). The module also provides a rectangle-drawing function useful for framing text boxes or for other purposes.

The module *curses.textpad* defines the following function:

curses.textpad.rectangle(*win*, *uly*, *ulx*, *lry*, *lrx*)

Draw a rectangle. The first argument must be a window object; the remaining arguments are coordinates relative to that window. The second and third arguments are the y and x coordinates of the upper left hand corner of the rectangle to be drawn; the fourth and fifth arguments are the y and x coordinates of the lower right hand corner. The rectangle will be drawn using VT100/IBM PC forms characters on terminals that make this possible (including xterm and most other software terminal emulators). Otherwise it will be drawn with ASCII dashes, vertical bars, and plus signs.

16.11.1 Textbox objects

You can instantiate a *Textbox* object as follows:

class curses.textpad.Textbox(*win*)

Return a textbox widget object. The *win* argument should be a curses *window* object in which the textbox is to be contained. The edit cursor of the textbox is initially located at the upper left hand corner of the containing window, with coordinates `(0, 0)`. The instance's *stripspaces* flag is initially on.

Textbox objects have the following methods:

edit(*[validator]*)

This is the entry point you will normally use. It accepts editing keystrokes until one of the termination keystrokes is entered. If *validator* is supplied, it must be a function. It will be called for each keystroke entered with the keystroke as a parameter; command dispatch is done on the result. This method returns the window contents as a string; whether blanks in the window are included is affected by the *stripspaces* attribute.

do_command(*ch*)

Process a single command keystroke. Here are the supported special keystrokes:

Keystroke	Action
Control-A	Go to left edge of window.
Control-B	Cursor left, wrapping to previous line if appropriate.
Control-D	Delete character under cursor.
Control-E	Go to right edge (stripspaces off) or end of line (stripspaces on).
Control-F	Cursor right, wrapping to next line when appropriate.
Control-G	Terminate, returning the window contents.
Control-H	Delete character backward.
Control-J	Terminate if the window is 1 line, otherwise insert newline.
Control-K	If line is blank, delete it, otherwise clear to end of line.
Control-L	Refresh screen.
Control-N	Cursor down; move down one line.
Control-O	Insert a blank line at cursor location.
Control-P	Cursor up; move up one line.

Move operations do nothing if the cursor is at an edge where the movement is not possible. The following synonyms are supported where possible:

Constant	Keystroke
KEY_LEFT	Control-B
KEY_RIGHT	Control-F
KEY_UP	Control-P
KEY_DOWN	Control-N
KEY_BACKSPACE	Control-h

All other keystrokes are treated as a command to insert the given character and move right (with line wrapping).

gather()
Return the window contents as a string; whether blanks in the window are included is affected by the *stripspaces* member.

stripspaces
This attribute is a flag which controls the interpretation of blanks in the window. When it is on, trailing blanks on each line are ignored; any cursor motion that would land the cursor on a trailing blank goes to the end of that line instead, and trailing blanks are stripped when the window contents are gathered.

16.12 curses.ascii — Utilities for ASCII characters

The *curses.ascii* module supplies name constants for ASCII characters and functions to test membership in various ASCII character classes. The constants supplied are names for control characters as follows:

Name	Meaning
NUL	
SOH	Start of heading, console interrupt
STX	Start of text
ETX	End of text
EOT	End of transmission

Continued on next page

Table 3 – continued from previous page

Name	Meaning
ENQ	Enquiry, goes with ACK flow control
ACK	Acknowledgement
BEL	Bell
BS	Backspace
TAB	Tab
HT	Alias for TAB: "Horizontal tab"
LF	Line feed
NL	Alias for LF: "New line"
VT	Vertical tab
FF	Form feed
CR	Carriage return
SO	Shift-out, begin alternate character set
SI	Shift-in, resume default character set
DLE	Data-link escape
DC1	XON, for flow control
DC2	Device control 2, block-mode flow control
DC3	XOFF, for flow control
DC4	Device control 4
NAK	Negative acknowledgement
SYN	Synchronous idle
ETB	End transmission block
CAN	Cancel
EM	End of medium
SUB	Substitute
ESC	Escape
FS	File separator
GS	Group separator
RS	Record separator, block-mode terminator
US	Unit separator
SP	Space
DEL	Delete

Note that many of these have little practical significance in modern usage. The mnemonics derive from teleprinter conventions that predate digital computers.

The module supplies the following functions, patterned on those in the standard C library:

curses.ascii.isalnum(*c*)
Checks for an ASCII alphanumeric character; it is equivalent to `isalpha(c) or isdigit(c)`.

curses.ascii.isalpha(*c*)
Checks for an ASCII alphabetic character; it is equivalent to `isupper(c) or islower(c)`.

curses.ascii.isascii(*c*)
Checks for a character value that fits in the 7-bit ASCII set.

curses.ascii.isblank(*c*)
Checks for an ASCII whitespace character; space or horizontal tab.

curses.ascii.iscntrl(*c*)
Checks for an ASCII control character (in the range 0x00 to 0x1f or 0x7f).

curses.ascii.isdigit(*c*)
Checks for an ASCII decimal digit, `'0'` through `'9'`. This is equivalent to `c in string.digits`.

curses.ascii.**isgraph**(*c*)
Checks for ASCII any printable character except space.

curses.ascii.**islower**(*c*)
Checks for an ASCII lower-case character.

curses.ascii.**isprint**(*c*)
Checks for any ASCII printable character including space.

curses.ascii.**ispunct**(*c*)
Checks for any printable ASCII character which is not a space or an alphanumeric character.

curses.ascii.**isspace**(*c*)
Checks for ASCII white-space characters; space, line feed, carriage return, form feed, horizontal tab, vertical tab.

curses.ascii.**isupper**(*c*)
Checks for an ASCII uppercase letter.

curses.ascii.**isxdigit**(*c*)
Checks for an ASCII hexadecimal digit. This is equivalent to `c in string.hexdigits`.

curses.ascii.**isctrl**(*c*)
Checks for an ASCII control character (ordinal values 0 to 31).

curses.ascii.**ismeta**(*c*)
Checks for a non-ASCII character (ordinal values 0x80 and above).

These functions accept either integers or single-character strings; when the argument is a string, it is first converted using the built-in function *ord()*.

Note that all these functions check ordinal bit values derived from the character of the string you pass in; they do not actually know anything about the host machine's character encoding.

The following two functions take either a single-character string or integer byte value; they return a value of the same type.

curses.ascii.**ascii**(*c*)
Return the ASCII value corresponding to the low 7 bits of *c*.

curses.ascii.**ctrl**(*c*)
Return the control character corresponding to the given character (the character bit value is bitwise-anded with 0x1f).

curses.ascii.**alt**(*c*)
Return the 8-bit character corresponding to the given ASCII character (the character bit value is bitwise-ored with 0x80).

The following function takes either a single-character string or integer value; it returns a string.

curses.ascii.**unctrl**(*c*)
Return a string representation of the ASCII character *c*. If *c* is printable, this string is the character itself. If the character is a control character (0x00–0x1f) the string consists of a caret (`'^'`) followed by the corresponding uppercase letter. If the character is an ASCII delete (0x7f) the string is `'^?'`. If the character has its meta bit (0x80) set, the meta bit is stripped, the preceding rules applied, and `'!'` prepended to the result.

curses.ascii.**controlnames**
A 33-element string array that contains the ASCII mnemonics for the thirty-two ASCII control characters from 0 (NUL) to 0x1f (US), in order, plus the mnemonic `SP` for the space character.

16.13 curses.panel — A panel stack extension for curses

Panels are windows with the added feature of depth, so they can be stacked on top of each other, and only the visible portions of each window will be displayed. Panels can be added, moved up or down in the stack, and removed.

16.13.1 Functions

The module *curses.panel* defines the following functions:

curses.panel.bottom_panel()
Returns the bottom panel in the panel stack.

curses.panel.new_panel(*win*)
Returns a panel object, associating it with the given window *win*. Be aware that you need to keep the returned panel object referenced explicitly. If you don't, the panel object is garbage collected and removed from the panel stack.

curses.panel.top_panel()
Returns the top panel in the panel stack.

curses.panel.update_panels()
Updates the virtual screen after changes in the panel stack. This does not call *curses.doupdate()*, so you'll have to do this yourself.

16.13.2 Panel Objects

Panel objects, as returned by *new_panel()* above, are windows with a stacking order. There's always a window associated with a panel which determines the content, while the panel methods are responsible for the window's depth in the panel stack.

Panel objects have the following methods:

Panel.above()
Returns the panel above the current panel.

Panel.below()
Returns the panel below the current panel.

Panel.bottom()
Push the panel to the bottom of the stack.

Panel.hidden()
Returns `True` if the panel is hidden (not visible), `False` otherwise.

Panel.hide()
Hide the panel. This does not delete the object, it just makes the window on screen invisible.

Panel.move(*y*, *x*)
Move the panel to the screen coordinates `(y, x)`.

Panel.replace(*win*)
Change the window associated with the panel to the window *win*.

Panel.set_userptr(*obj*)
Set the panel's user pointer to *obj*. This is used to associate an arbitrary piece of data with the panel, and can be any Python object.

`Panel.show()`
Display the panel (which might have been hidden).

`Panel.top()`
Push panel to the top of the stack.

`Panel.userptr()`
Returns the user pointer for the panel. This might be any Python object.

`Panel.window()`
Returns the window object associated with the panel.

16.14 `platform` — Access to underlying platform's identifying data

Source code: Lib/platform.py

Note: Specific platforms listed alphabetically, with Linux included in the Unix section.

16.14.1 Cross Platform

`platform.architecture(`*executable=sys.executable*, *bits=''*, *linkage=''*`)`
Queries the given executable (defaults to the Python interpreter binary) for various architecture information.

Returns a tuple `(bits, linkage)` which contain information about the bit architecture and the linkage format used for the executable. Both values are returned as strings.

Values that cannot be determined are returned as given by the parameter presets. If bits is given as `''`, the `sizeof(pointer)` (or `sizeof(long)` on Python version < 1.5.2) is used as indicator for the supported pointer size.

The function relies on the system's `file` command to do the actual work. This is available on most if not all Unix platforms and some non-Unix platforms and then only if the executable points to the Python interpreter. Reasonable defaults are used when the above needs are not met.

Note: On Mac OS X (and perhaps other platforms), executable files may be universal files containing multiple architectures.

To get at the "64-bitness" of the current interpreter, it is more reliable to query the *sys.maxsize* attribute:

```
is_64bits = sys.maxsize > 2**32
```

`platform.machine()`
Returns the machine type, e.g. `'i386'`. An empty string is returned if the value cannot be determined.

`platform.node()`
Returns the computer's network name (may not be fully qualified!). An empty string is returned if the value cannot be determined.

`platform.platform(`*aliased=0*, *terse=0*`)`
Returns a single string identifying the underlying platform with as much useful information as possible.

The output is intended to be *human readable* rather than machine parseable. It may look different on different platforms and this is intended.

If *aliased* is true, the function will use aliases for various platforms that report system names which differ from their common names, for example SunOS will be reported as Solaris. The *system_alias()* function is used to implement this.

Setting *terse* to true causes the function to return only the absolute minimum information needed to identify the platform.

platform.processor()
Returns the (real) processor name, e.g. 'amdk6'.

An empty string is returned if the value cannot be determined. Note that many platforms do not provide this information or simply return the same value as for *machine()*. NetBSD does this.

platform.python_build()
Returns a tuple (buildno, builddate) stating the Python build number and date as strings.

platform.python_compiler()
Returns a string identifying the compiler used for compiling Python.

platform.python_branch()
Returns a string identifying the Python implementation SCM branch.

platform.python_implementation()
Returns a string identifying the Python implementation. Possible return values are: 'CPython', 'IronPython', 'Jython', 'PyPy'.

platform.python_revision()
Returns a string identifying the Python implementation SCM revision.

platform.python_version()
Returns the Python version as string 'major.minor.patchlevel'.

Note that unlike the Python sys.version, the returned value will always include the patchlevel (it defaults to 0).

platform.python_version_tuple()
Returns the Python version as tuple (major, minor, patchlevel) of strings.

Note that unlike the Python sys.version, the returned value will always include the patchlevel (it defaults to '0').

platform.release()
Returns the system's release, e.g. '2.2.0' or 'NT' An empty string is returned if the value cannot be determined.

platform.system()
Returns the system/OS name, e.g. 'Linux', 'Windows', or 'Java'. An empty string is returned if the value cannot be determined.

platform.system_alias(*system*, *release*, *version*)
Returns (system, release, version) aliased to common marketing names used for some systems. It also does some reordering of the information in some cases where it would otherwise cause confusion.

platform.version()
Returns the system's release version, e.g. '#3 on degas'. An empty string is returned if the value cannot be determined.

platform.uname()
Fairly portable uname interface. Returns a *namedtuple()* containing six attributes: *system*, *node*, *release*, *version*, *machine*, and *processor*.

Note that this adds a sixth attribute (*processor*) not present in the *os.uname()* result. Also, the attribute names are different for the first two attributes; *os.uname()* names them `sysname` and `nodename`.

Entries which cannot be determined are set to `''`.

Changed in version 3.3: Result changed from a tuple to a namedtuple.

16.14.2 Java Platform

`platform.java_ver`(*release=''*, *vendor=''*, *vminfo=('', '', '')*, *osinfo=('', '', '')*)

Version interface for Jython.

Returns a tuple `(release, vendor, vminfo, osinfo)` with *vminfo* being a tuple `(vm_name, vm_release, vm_vendor)` and *osinfo* being a tuple `(os_name, os_version, os_arch)`. Values which cannot be determined are set to the defaults given as parameters (which all default to `''`).

16.14.3 Windows Platform

`platform.win32_ver`(*release=''*, *version=''*, *csd=''*, *ptype=''*)

Get additional version information from the Windows Registry and return a tuple `(release, version, csd, ptype)` referring to OS release, version number, CSD level (service pack) and OS type (multi/single processor).

As a hint: *ptype* is `'Uniprocessor Free'` on single processor NT machines and `'Multiprocessor Free'` on multi processor machines. The *'Free'* refers to the OS version being free of debugging code. It could also state *'Checked'* which means the OS version uses debugging code, i.e. code that checks arguments, ranges, etc.

Note: This function works best with Mark Hammond's `win32all` package installed, but also on Python 2.3 and later (support for this was added in Python 2.6). It obviously only runs on Win32 compatible platforms.

Win95/98 specific

`platform.popen`(*cmd*, *mode='r'*, *bufsize=-1*)

Portable *popen()* interface. Find a working popen implementation preferring `win32pipe.popen()`. On Windows NT, `win32pipe.popen()` should work; on Windows 9x it hangs due to bugs in the MS C library.

Deprecated since version 3.3: This function is obsolete. Use the *subprocess* module. Check especially the *Replacing Older Functions with the subprocess Module* section.

16.14.4 Mac OS Platform

`platform.mac_ver`(*release=''*, *versioninfo=('', '', '')*, *machine=''*)

Get Mac OS version information and return it as tuple `(release, versioninfo, machine)` with *versioninfo* being a tuple `(version, dev_stage, non_release_version)`.

Entries which cannot be determined are set to `''`. All tuple entries are strings.

16.14.5 Unix Platforms

`platform.dist`(*distname=''*, *version=''*, *id=''*, *supported_dists=('SuSE', 'debian', 'redhat', 'mandrake', ...)*)
This is another name for *linux_distribution()*.

Deprecated since version 3.5, will be removed in version 3.8: See alternative like the distro package.

`platform.linux_distribution`(*distname=''*, *version=''*, *id=''*, *supported_dists=('SuSE', 'debian', 'redhat', 'mandrake', ...)*, *full_distribution_name=1*)
Tries to determine the name of the Linux OS distribution name.

`supported_dists` may be given to define the set of Linux distributions to look for. It defaults to a list of currently supported Linux distributions identified by their release file name.

If `full_distribution_name` is true (default), the full distribution read from the OS is returned. Otherwise the short name taken from `supported_dists` is used.

Returns a tuple `(distname,version,id)` which defaults to the args given as parameters. `id` is the item in parentheses after the version number. It is usually the version codename.

Deprecated since version 3.5, will be removed in version 3.8: See alternative like the distro package.

`platform.libc_ver`(*executable=sys.executable*, *lib=''*, *version=''*, *chunksize=2048*)
Tries to determine the libc version against which the file executable (defaults to the Python interpreter) is linked. Returns a tuple of strings `(lib, version)` which default to the given parameters in case the lookup fails.

Note that this function has intimate knowledge of how different libc versions add symbols to the executable is probably only usable for executables compiled using `gcc`.

The file is read and scanned in chunks of *chunksize* bytes.

16.15 `errno` — Standard errno system symbols

This module makes available standard `errno` system symbols. The value of each symbol is the corresponding integer value. The names and descriptions are borrowed from `linux/include/errno.h`, which should be pretty all-inclusive.

`errno.errorcode`
Dictionary providing a mapping from the errno value to the string name in the underlying system. For instance, `errno.errorcode[errno.EPERM]` maps to `'EPERM'`.

To translate a numeric error code to an error message, use *os.strerror()*.

Of the following list, symbols that are not used on the current platform are not defined by the module. The specific list of defined symbols is available as `errno.errorcode.keys()`. Symbols available can include:

`errno.EPERM`
Operation not permitted

`errno.ENOENT`
No such file or directory

`errno.ESRCH`
No such process

`errno.EINTR`
Interrupted system call.

See also:

This error is mapped to the exception *InterruptedError*.

errno.**EIO**
I/O error

errno.**ENXIO**
No such device or address

errno.**E2BIG**
Arg list too long

errno.**ENOEXEC**
Exec format error

errno.**EBADF**
Bad file number

errno.**ECHILD**
No child processes

errno.**EAGAIN**
Try again

errno.**ENOMEM**
Out of memory

errno.**EACCES**
Permission denied

errno.**EFAULT**
Bad address

errno.**ENOTBLK**
Block device required

errno.**EBUSY**
Device or resource busy

errno.**EEXIST**
File exists

errno.**EXDEV**
Cross-device link

errno.**ENODEV**
No such device

errno.**ENOTDIR**
Not a directory

errno.**EISDIR**
Is a directory

errno.**EINVAL**
Invalid argument

errno.**ENFILE**
File table overflow

errno.**EMFILE**
Too many open files

errno.**ENOTTY**
Not a typewriter

errno.**ETXTBSY**
Text file busy

errno.**EFBIG**
File too large

errno.**ENOSPC**
No space left on device

errno.**ESPIPE**
Illegal seek

errno.**EROFS**
Read-only file system

errno.**EMLINK**
Too many links

errno.**EPIPE**
Broken pipe

errno.**EDOM**
Math argument out of domain of func

errno.**ERANGE**
Math result not representable

errno.**EDEADLK**
Resource deadlock would occur

errno.**ENAMETOOLONG**
File name too long

errno.**ENOLCK**
No record locks available

errno.**ENOSYS**
Function not implemented

errno.**ENOTEMPTY**
Directory not empty

errno.**ELOOP**
Too many symbolic links encountered

errno.**EWOULDBLOCK**
Operation would block

errno.**ENOMSG**
No message of desired type

errno.**EIDRM**
Identifier removed

errno.**ECHRNG**
Channel number out of range

errno.**EL2NSYNC**
Level 2 not synchronized

errno.**EL3HLT**
Level 3 halted

errno.**EL3RST**
Level 3 reset

errno.**ELNRNG**
Link number out of range

errno.**EUNATCH**
Protocol driver not attached

errno.**ENOCSI**
No CSI structure available

errno.**EL2HLT**
Level 2 halted

errno.**EBADE**
Invalid exchange

errno.**EBADR**
Invalid request descriptor

errno.**EXFULL**
Exchange full

errno.**ENOANO**
No anode

errno.**EBADRQC**
Invalid request code

errno.**EBADSLT**
Invalid slot

errno.**EDEADLOCK**
File locking deadlock error

errno.**EBFONT**
Bad font file format

errno.**ENOSTR**
Device not a stream

errno.**ENODATA**
No data available

errno.**ETIME**
Timer expired

errno.**ENOSR**
Out of streams resources

errno.**ENONET**
Machine is not on the network

errno.**ENOPKG**
Package not installed

errno.**EREMOTE**
Object is remote

errno.**ENOLINK**
Link has been severed

errno.**EADV**
Advertise error

errno.**ESRMNT**
Srmount error

errno.**ECOMM**
Communication error on send

errno.**EPROTO**
Protocol error

errno.**EMULTIHOP**
Multihop attempted

errno.**EDOTDOT**
RFS specific error

errno.**EBADMSG**
Not a data message

errno.**EOVERFLOW**
Value too large for defined data type

errno.**ENOTUNIQ**
Name not unique on network

errno.**EBADFD**
File descriptor in bad state

errno.**EREMCHG**
Remote address changed

errno.**ELIBACC**
Can not access a needed shared library

errno.**ELIBBAD**
Accessing a corrupted shared library

errno.**ELIBSCN**
.lib section in a.out corrupted

errno.**ELIBMAX**
Attempting to link in too many shared libraries

errno.**ELIBEXEC**
Cannot exec a shared library directly

errno.**EILSEQ**
Illegal byte sequence

errno.**ERESTART**
Interrupted system call should be restarted

errno.**ESTRPIPE**
Streams pipe error

errno.**EUSERS**
Too many users

errno.**ENOTSOCK**
Socket operation on non-socket

errno.**EDESTADDRREQ**
Destination address required

errno.**EMSGSIZE**
Message too long

errno.**EPROTOTYPE**
Protocol wrong type for socket

errno.**ENOPROTOOPT**
Protocol not available

errno.**EPROTONOSUPPORT**
Protocol not supported

errno.**ESOCKTNOSUPPORT**
Socket type not supported

errno.**EOPNOTSUPP**
Operation not supported on transport endpoint

errno.**EPFNOSUPPORT**
Protocol family not supported

errno.**EAFNOSUPPORT**
Address family not supported by protocol

errno.**EADDRINUSE**
Address already in use

errno.**EADDRNOTAVAIL**
Cannot assign requested address

errno.**ENETDOWN**
Network is down

errno.**ENETUNREACH**
Network is unreachable

errno.**ENETRESET**
Network dropped connection because of reset

errno.**ECONNABORTED**
Software caused connection abort

errno.**ECONNRESET**
Connection reset by peer

errno.**ENOBUFS**
No buffer space available

errno.**EISCONN**
Transport endpoint is already connected

errno.**ENOTCONN**
Transport endpoint is not connected

errno.**ESHUTDOWN**
Cannot send after transport endpoint shutdown

errno.**ETOOMANYREFS**
Too many references: cannot splice

errno.**ETIMEDOUT**
Connection timed out

errno.**ECONNREFUSED**
Connection refused

errno.**EHOSTDOWN**
Host is down

errno.**EHOSTUNREACH**
No route to host

errno.**EALREADY**
Operation already in progress

errno.EINPROGRESS
Operation now in progress

errno.ESTALE
Stale NFS file handle

errno.EUCLEAN
Structure needs cleaning

errno.ENOTNAM
Not a XENIX named type file

errno.ENAVAIL
No XENIX semaphores available

errno.EISNAM
Is a named type file

errno.EREMOTEIO
Remote I/O error

errno.EDQUOT
Quota exceeded

16.16 ctypes — A foreign function library for Python

ctypes is a foreign function library for Python. It provides C compatible data types, and allows calling functions in DLLs or shared libraries. It can be used to wrap these libraries in pure Python.

16.16.1 ctypes tutorial

Note: The code samples in this tutorial use *doctest* to make sure that they actually work. Since some code samples behave differently under Linux, Windows, or Mac OS X, they contain doctest directives in comments.

Note: Some code samples reference the ctypes *c_int* type. On platforms where `sizeof(long) == sizeof(int)` it is an alias to *c_long*. So, you should not be confused if *c_long* is printed if you would expect *c_int* — they are actually the same type.

Loading dynamic link libraries

ctypes exports the *cdll*, and on Windows *windll* and *oledll* objects, for loading dynamic link libraries.

You load libraries by accessing them as attributes of these objects. *cdll* loads libraries which export functions using the standard `cdecl` calling convention, while *windll* libraries call functions using the `stdcall` calling convention. *oledll* also uses the `stdcall` calling convention, and assumes the functions return a Windows `HRESULT` error code. The error code is used to automatically raise an *OSError* exception when the function call fails.

Changed in version 3.3: Windows errors used to raise *WindowsError*, which is now an alias of *OSError*.

Here are some examples for Windows. Note that `msvcrt` is the MS standard C library containing most standard C functions, and uses the cdecl calling convention:

```
>>> from ctypes import *
>>> print(windll.kernel32)
<WinDLL 'kernel32', handle ... at ...>
>>> print(cdll.msvcrt)
<CDLL 'msvcrt', handle ... at ...>
>>> libc = cdll.msvcrt
>>>
```

Windows appends the usual `.dll` file suffix automatically.

Note: Accessing the standard C library through `cdll.msvcrt` will use an outdated version of the library that may be incompatible with the one being used by Python. Where possible, use native Python functionality, or else import and use the `msvcrt` module.

On Linux, it is required to specify the filename *including* the extension to load a library, so attribute access can not be used to load libraries. Either the `LoadLibrary()` method of the dll loaders should be used, or you should load the library by creating an instance of CDLL by calling the constructor:

```
>>> cdll.LoadLibrary("libc.so.6")
<CDLL 'libc.so.6', handle ... at ...>
>>> libc = CDLL("libc.so.6")
>>> libc
<CDLL 'libc.so.6', handle ... at ...>
>>>
```

Accessing functions from loaded dlls

Functions are accessed as attributes of dll objects:

```
>>> from ctypes import *
>>> libc.printf
<_FuncPtr object at 0x...>
>>> print(windll.kernel32.GetModuleHandleA)
<_FuncPtr object at 0x...>
>>> print(windll.kernel32.MyOwnFunction)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "ctypes.py", line 239, in __getattr__
    func = _StdcallFuncPtr(name, self)
AttributeError: function 'MyOwnFunction' not found
>>>
```

Note that win32 system dlls like `kernel32` and `user32` often export ANSI as well as UNICODE versions of a function. The UNICODE version is exported with an `W` appended to the name, while the ANSI version is exported with an `A` appended to the name. The win32 `GetModuleHandle` function, which returns a *module handle* for a given module name, has the following C prototype, and a macro is used to expose one of them as `GetModuleHandle` depending on whether UNICODE is defined or not:

```
/* ANSI version */
HMODULE GetModuleHandleA(LPCSTR lpModuleName);
/* UNICODE version */
HMODULE GetModuleHandleW(LPCWSTR lpModuleName);
```

windll does not try to select one of them by magic, you must access the version you need by specifying `GetModuleHandleA` or `GetModuleHandleW` explicitly, and then call it with bytes or string objects respectively.

Sometimes, dlls export functions with names which aren't valid Python identifiers, like `"??2@YAPAXI@Z"`. In this case you have to use *getattr()* to retrieve the function:

```
>>> getattr(cdll.msvcrt, "??2@YAPAXI@Z")
<_FuncPtr object at 0x...>
>>>
```

On Windows, some dlls export functions not by name but by ordinal. These functions can be accessed by indexing the dll object with the ordinal number:

```
>>> cdll.kernel32[1]
<_FuncPtr object at 0x...>
>>> cdll.kernel32[0]
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "ctypes.py", line 310, in __getitem__
    func = _StdcallFuncPtr(name, self)
AttributeError: function ordinal 0 not found
>>>
```

Calling functions

You can call these functions like any other Python callable. This example uses the `time()` function, which returns system time in seconds since the Unix epoch, and the `GetModuleHandleA()` function, which returns a win32 module handle.

This example calls both functions with a NULL pointer (`None` should be used as the NULL pointer):

```
>>> print(libc.time(None))
1150640792
>>> print(hex(windll.kernel32.GetModuleHandleA(None)))
0x1d000000
>>>
```

Note: *ctypes* may raise a *ValueError* after calling the function, if it detects that an invalid number of arguments were passed. This behavior should not be relied upon. It is deprecated in 3.6.2, and will be removed in 3.7.

ValueError is raised when you call an `stdcall` function with the `cdecl` calling convention, or vice versa:

```
>>> cdll.kernel32.GetModuleHandleA(None)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: Procedure probably called with not enough arguments (4 bytes missing)
>>>

>>> windll.msvcrt.printf(b"spam")
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: Procedure probably called with too many arguments (4 bytes in excess)
>>>
```

To find out the correct calling convention you have to look into the C header file or the documentation for the function you want to call.

On Windows, *ctypes* uses win32 structured exception handling to prevent crashes from general protection faults when functions are called with invalid argument values:

```
>>> windll.kernel32.GetModuleHandleA(32)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
OSError: exception: access violation reading 0x00000020
>>>
```

There are, however, enough ways to crash Python with *ctypes*, so you should be careful anyway. The *faulthandler* module can be helpful in debugging crashes (e.g. from segmentation faults produced by erroneous C library calls).

`None`, integers, bytes objects and (unicode) strings are the only native Python objects that can directly be used as parameters in these function calls. `None` is passed as a C `NULL` pointer, bytes objects and strings are passed as pointer to the memory block that contains their data (`char *` or `wchar_t *`). Python integers are passed as the platforms default C `int` type, their value is masked to fit into the C type.

Before we move on calling functions with other parameter types, we have to learn more about *ctypes* data types.

Fundamental data types

ctypes defines a number of primitive C compatible data types:

ctypes type	C type	Python type
c_bool	_Bool	bool (1)
c_char	char	1-character bytes object
c_wchar	wchar_t	1-character string
c_byte	char	int
c_ubyte	unsigned char	int
c_short	short	int
c_ushort	unsigned short	int
c_int	int	int
c_uint	unsigned int	int
c_long	long	int
c_ulong	unsigned long	int
c_longlong	__int64 or long long	int
c_ulonglong	unsigned __int64 or unsigned long long	int
c_size_t	size_t	int
c_ssize_t	ssize_t or Py_ssize_t	int
c_float	float	float
c_double	double	float
c_longdouble	long double	float
c_char_p	char * (NUL terminated)	bytes object or None
c_wchar_p	wchar_t * (NUL terminated)	string or None
c_void_p	void *	int or None

1. The constructor accepts any object with a truth value.

All these types can be created by calling them with an optional initializer of the correct type and value:

```
>>> c_int()
c_long(0)
>>> c_wchar_p("Hello, World")
```

(continues on next page)

(continued from previous page)

```
c_wchar_p(140018365411392)
>>> c_ushort(-3)
c_ushort(65533)
>>>
```

Since these types are mutable, their value can also be changed afterwards:

```
>>> i = c_int(42)
>>> print(i)
c_long(42)
>>> print(i.value)
42
>>> i.value = -99
>>> print(i.value)
-99
>>>
```

Assigning a new value to instances of the pointer types *c_char_p*, *c_wchar_p*, and *c_void_p* changes the *memory location* they point to, *not the contents* of the memory block (of course not, because Python bytes objects are immutable):

```
>>> s = "Hello, World"
>>> c_s = c_wchar_p(s)
>>> print(c_s)
c_wchar_p(139966785747344)
>>> print(c_s.value)
Hello World
>>> c_s.value = "Hi, there"
>>> print(c_s)              # the memory location has changed
c_wchar_p(139966783348904)
>>> print(c_s.value)
Hi, there
>>> print(s)                # first object is unchanged
Hello, World
>>>
```

You should be careful, however, not to pass them to functions expecting pointers to mutable memory. If you need mutable memory blocks, ctypes has a *create_string_buffer()* function which creates these in various ways. The current memory block contents can be accessed (or changed) with the `raw` property; if you want to access it as NUL terminated string, use the `value` property:

```
>>> from ctypes import *
>>> p = create_string_buffer(3)            # create a 3 byte buffer, initialized to NUL bytes
>>> print(sizeof(p), repr(p.raw))
3 b'\x00\x00\x00'
>>> p = create_string_buffer(b"Hello")     # create a buffer containing a NUL terminated string
>>> print(sizeof(p), repr(p.raw))
6 b'Hello\x00'
>>> print(repr(p.value))
b'Hello'
>>> p = create_string_buffer(b"Hello", 10) # create a 10 byte buffer
>>> print(sizeof(p), repr(p.raw))
10 b'Hello\x00\x00\x00\x00\x00'
>>> p.value = b"Hi"
>>> print(sizeof(p), repr(p.raw))
10 b'Hi\x00lo\x00\x00\x00\x00\x00'
>>>
```

The *create_string_buffer()* function replaces the `c_buffer()` function (which is still available as an alias), as well as the `c_string()` function from earlier ctypes releases. To create a mutable memory block containing unicode characters of the C type `wchar_t` use the *create_unicode_buffer()* function.

Calling functions, continued

Note that printf prints to the real standard output channel, *not* to *sys.stdout*, so these examples will only work at the console prompt, not from within *IDLE* or *PythonWin*:

```
>>> printf = libc.printf
>>> printf(b"Hello, %s\n", b"World!")
Hello, World!
14
>>> printf(b"Hello, %S\n", "World!")
Hello, World!
14
>>> printf(b"%d bottles of beer\n", 42)
42 bottles of beer
19
>>> printf(b"%f bottles of beer\n", 42.5)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ArgumentError: argument 2: exceptions.TypeError: Don't know how to convert parameter 2
>>>
```

As has been mentioned before, all Python types except integers, strings, and bytes objects have to be wrapped in their corresponding *ctypes* type, so that they can be converted to the required C data type:

```
>>> printf(b"An int %d, a double %f\n", 1234, c_double(3.14))
An int 1234, a double 3.140000
31
>>>
```

Calling functions with your own custom data types

You can also customize *ctypes* argument conversion to allow instances of your own classes be used as function arguments. *ctypes* looks for an `_as_parameter_` attribute and uses this as the function argument. Of course, it must be one of integer, string, or bytes:

```
>>> class Bottles:
...     def __init__(self, number):
...         self._as_parameter_ = number
...
>>> bottles = Bottles(42)
>>> printf(b"%d bottles of beer\n", bottles)
42 bottles of beer
19
>>>
```

If you don't want to store the instance's data in the `_as_parameter_` instance variable, you could define a *property* which makes the attribute available on request.

Specifying the required argument types (function prototypes)

It is possible to specify the required argument types of functions exported from DLLs by setting the `argtypes` attribute.

`argtypes` must be a sequence of C data types (the `printf` function is probably not a good example here, because it takes a variable number and different types of parameters depending on the format string, on the other hand this is quite handy to experiment with this feature):

```
>>> printf.argtypes = [c_char_p, c_char_p, c_int, c_double]
>>> printf(b"String '%s', Int %d, Double %f\n", b"Hi", 10, 2.2)
String 'Hi', Int 10, Double 2.200000
37
>>>
```

Specifying a format protects against incompatible argument types (just as a prototype for a C function), and tries to convert the arguments to valid types:

```
>>> printf(b"%d %d %d", 1, 2, 3)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ArgumentError: argument 2: exceptions.TypeError: wrong type
>>> printf(b"%s %d %f\n", b"X", 2, 3)
X 2 3.000000
13
>>>
```

If you have defined your own classes which you pass to function calls, you have to implement a `from_param()` class method for them to be able to use them in the `argtypes` sequence. The `from_param()` class method receives the Python object passed to the function call, it should do a typecheck or whatever is needed to make sure this object is acceptable, and then return the object itself, its `_as_parameter_` attribute, or whatever you want to pass as the C function argument in this case. Again, the result should be an integer, string, bytes, a *ctypes* instance, or an object with an `_as_parameter_` attribute.

Return types

By default functions are assumed to return the C `int` type. Other return types can be specified by setting the `restype` attribute of the function object.

Here is a more advanced example, it uses the `strchr` function, which expects a string pointer and a char, and returns a pointer to a string:

```
>>> strchr = libc.strchr
>>> strchr(b"abcdef", ord("d"))
8059983
>>> strchr.restype = c_char_p    # c_char_p is a pointer to a string
>>> strchr(b"abcdef", ord("d"))
b'def'
>>> print(strchr(b"abcdef", ord("x")))
None
>>>
```

If you want to avoid the `ord("x")` calls above, you can set the `argtypes` attribute, and the second argument will be converted from a single character Python bytes object into a C char:

```
>>> strchr.restype = c_char_p
>>> strchr.argtypes = [c_char_p, c_char]
```

(continues on next page)

(continued from previous page)

```
>>> strchr(b"abcdef", b"d")
'def'
>>> strchr(b"abcdef", b"def")
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ArgumentError: argument 2: exceptions.TypeError: one character string expected
>>> print(strchr(b"abcdef", b"x"))
None
>>> strchr(b"abcdef", b"d")
'def'
>>>
```

You can also use a callable Python object (a function or a class for example) as the `restype` attribute, if the foreign function returns an integer. The callable will be called with the *integer* the C function returns, and the result of this call will be used as the result of your function call. This is useful to check for error return values and automatically raise an exception:

```
>>> GetModuleHandle = windll.kernel32.GetModuleHandleA
>>> def ValidHandle(value):
...     if value == 0:
...         raise WinError()
...     return value
...
>>>
>>> GetModuleHandle.restype = ValidHandle
>>> GetModuleHandle(None)
486539264
>>> GetModuleHandle("something silly")
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "<stdin>", line 3, in ValidHandle
OSError: [Errno 126] The specified module could not be found.
>>>
```

`WinError` is a function which will call Windows `FormatMessage()` api to get the string representation of an error code, and *returns* an exception. `WinError` takes an optional error code parameter, if no one is used, it calls *`GetLastError()`* to retrieve it.

Please note that a much more powerful error checking mechanism is available through the `errcheck` attribute; see the reference manual for details.

Passing pointers (or: passing parameters by reference)

Sometimes a C api function expects a *pointer* to a data type as parameter, probably to write into the corresponding location, or if the data is too large to be passed by value. This is also known as *passing parameters by reference*.

`ctypes` exports the *`byref()`* function which is used to pass parameters by reference. The same effect can be achieved with the *`pointer()`* function, although *`pointer()`* does a lot more work since it constructs a real pointer object, so it is faster to use *`byref()`* if you don't need the pointer object in Python itself:

```
>>> i = c_int()
>>> f = c_float()
>>> s = create_string_buffer(b'\000' * 32)
>>> print(i.value, f.value, repr(s.value))
0 0.0 b''
```

(continues on next page)

(continued from previous page)

```
>>> libc.sscanf(b"1 3.14 Hello", b"%d %f %s",
...             byref(i), byref(f), s)
3
>>> print(i.value, f.value, repr(s.value))
1 3.1400001049 b'Hello'
>>>
```

Structures and unions

Structures and unions must derive from the *Structure* and *Union* base classes which are defined in the *ctypes* module. Each subclass must define a `_fields_` attribute. `_fields_` must be a list of *2-tuples*, containing a *field name* and a *field type*.

The field type must be a *ctypes* type like *c_int*, or any other derived *ctypes* type: structure, union, array, pointer.

Here is a simple example of a POINT structure, which contains two integers named *x* and *y*, and also shows how to initialize a structure in the constructor:

```
>>> from ctypes import *
>>> class POINT(Structure):
...     _fields_ = [("x", c_int),
...                 ("y", c_int)]
...
>>> point = POINT(10, 20)
>>> print(point.x, point.y)
10 20
>>> point = POINT(y=5)
>>> print(point.x, point.y)
0 5
>>> POINT(1, 2, 3)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: too many initializers
>>>
```

You can, however, build much more complicated structures. A structure can itself contain other structures by using a structure as a field type.

Here is a RECT structure which contains two POINTs named *upperleft* and *lowerright*:

```
>>> class RECT(Structure):
...     _fields_ = [("upperleft", POINT),
...                 ("lowerright", POINT)]
...
>>> rc = RECT(point)
>>> print(rc.upperleft.x, rc.upperleft.y)
0 5
>>> print(rc.lowerright.x, rc.lowerright.y)
0 0
>>>
```

Nested structures can also be initialized in the constructor in several ways:

```
>>> r = RECT(POINT(1, 2), POINT(3, 4))
>>> r = RECT((1, 2), (3, 4))
```

Field *descriptor*s can be retrieved from the *class*, they are useful for debugging because they can provide useful information:

```
>>> print(POINT.x)
<Field type=c_long, ofs=0, size=4>
>>> print(POINT.y)
<Field type=c_long, ofs=4, size=4>
>>>
```

Warning: *ctypes* does not support passing unions or structures with bit-fields to functions by value. While this may work on 32-bit x86, it's not guaranteed by the library to work in the general case. Unions and structures with bit-fields should always be passed to functions by pointer.

Structure/union alignment and byte order

By default, Structure and Union fields are aligned in the same way the C compiler does it. It is possible to override this behavior be specifying a `_pack_` class attribute in the subclass definition. This must be set to a positive integer and specifies the maximum alignment for the fields. This is what `#pragma pack(n)` also does in MSVC.

ctypes uses the native byte order for Structures and Unions. To build structures with non-native byte order, you can use one of the *BigEndianStructure*, *LittleEndianStructure*, `BigEndianUnion`, and `LittleEndianUnion` base classes. These classes cannot contain pointer fields.

Bit fields in structures and unions

It is possible to create structures and unions containing bit fields. Bit fields are only possible for integer fields, the bit width is specified as the third item in the `_fields_` tuples:

```
>>> class Int(Structure):
...     _fields_ = [("first_16", c_int, 16),
...                 ("second_16", c_int, 16)]
...
>>> print(Int.first_16)
<Field type=c_long, ofs=0:0, bits=16>
>>> print(Int.second_16)
<Field type=c_long, ofs=0:16, bits=16>
>>>
```

Arrays

Arrays are sequences, containing a fixed number of instances of the same type.

The recommended way to create array types is by multiplying a data type with a positive integer:

```
TenPointsArrayType = POINT * 10
```

Here is an example of a somewhat artificial data type, a structure containing 4 POINTs among other stuff:

```
>>> from ctypes import *
>>> class POINT(Structure):
...     _fields_ = ("x", c_int), ("y", c_int)
...
```

(continues on next page)

(continued from previous page)

```
>>> class MyStruct(Structure):
...     _fields_ = [("a", c_int),
...                 ("b", c_float),
...                 ("point_array", POINT * 4)]
>>>
>>> print(len(MyStruct().point_array))
4
>>>
```

Instances are created in the usual way, by calling the class:

```
arr = TenPointsArrayType()
for pt in arr:
    print(pt.x, pt.y)
```

The above code print a series of `0 0` lines, because the array contents is initialized to zeros.

Initializers of the correct type can also be specified:

```
>>> from ctypes import *
>>> TenIntegers = c_int * 10
>>> ii = TenIntegers(1, 2, 3, 4, 5, 6, 7, 8, 9, 10)
>>> print(ii)
<c_long_Array_10 object at 0x...>
>>> for i in ii: print(i, end=" ")
...
1 2 3 4 5 6 7 8 9 10
>>>
```

Pointers

Pointer instances are created by calling the *pointer()* function on a *ctypes* type:

```
>>> from ctypes import *
>>> i = c_int(42)
>>> pi = pointer(i)
>>>
```

Pointer instances have a *contents* attribute which returns the object to which the pointer points, the `i` object above:

```
>>> pi.contents
c_long(42)
>>>
```

Note that *ctypes* does not have OOR (original object return), it constructs a new, equivalent object each time you retrieve an attribute:

```
>>> pi.contents is i
False
>>> pi.contents is pi.contents
False
>>>
```

Assigning another *c_int* instance to the pointer's contents attribute would cause the pointer to point to the memory location where this is stored:

```
>>> i = c_int(99)
>>> pi.contents = i
>>> pi.contents
c_long(99)
>>>
```

Pointer instances can also be indexed with integers:

```
>>> pi[0]
99
>>>
```

Assigning to an integer index changes the pointed to value:

```
>>> print(i)
c_long(99)
>>> pi[0] = 22
>>> print(i)
c_long(22)
>>>
```

It is also possible to use indexes different from 0, but you must know what you're doing, just as in C: You can access or change arbitrary memory locations. Generally you only use this feature if you receive a pointer from a C function, and you *know* that the pointer actually points to an array instead of a single item.

Behind the scenes, the *pointer()* function does more than simply create pointer instances, it has to create pointer *types* first. This is done with the *POINTER()* function, which accepts any *ctypes* type, and returns a new type:

```
>>> PI = POINTER(c_int)
>>> PI
<class 'ctypes.LP_c_long'>
>>> PI(42)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: expected c_long instead of int
>>> PI(c_int(42))
<ctypes.LP_c_long object at 0x...>
>>>
```

Calling the pointer type without an argument creates a `NULL` pointer. `NULL` pointers have a `False` boolean value:

```
>>> null_ptr = POINTER(c_int)()
>>> print(bool(null_ptr))
False
>>>
```

ctypes checks for `NULL` when dereferencing pointers (but dereferencing invalid non-`NULL` pointers would crash Python):

```
>>> null_ptr[0]
Traceback (most recent call last):
    ....
ValueError: NULL pointer access
>>>
```

(continues on next page)

(continued from previous page)

```
>>> null_ptr[0] = 1234
Traceback (most recent call last):
    ....
ValueError: NULL pointer access
>>>
```

Type conversions

Usually, ctypes does strict type checking. This means, if you have `POINTER(c_int)` in the `argtypes` list of a function or as the type of a member field in a structure definition, only instances of exactly the same type are accepted. There are some exceptions to this rule, where ctypes accepts other objects. For example, you can pass compatible array instances instead of pointer types. So, for `POINTER(c_int)`, ctypes accepts an array of c_int:

```
>>> class Bar(Structure):
...     _fields_ = [("count", c_int), ("values", POINTER(c_int))]
...
>>> bar = Bar()
>>> bar.values = (c_int * 3)(1, 2, 3)
>>> bar.count = 3
>>> for i in range(bar.count):
...     print(bar.values[i])
...
1
2
3
>>>
```

In addition, if a function argument is explicitly declared to be a pointer type (such as `POINTER(c_int)`) in `argtypes`, an object of the pointed type (`c_int` in this case) can be passed to the function. ctypes will apply the required *byref()* conversion in this case automatically.

To set a POINTER type field to `NULL`, you can assign `None`:

```
>>> bar.values = None
>>>
```

Sometimes you have instances of incompatible types. In C, you can cast one type into another type. *ctypes* provides a *cast()* function which can be used in the same way. The `Bar` structure defined above accepts `POINTER(c_int)` pointers or *c_int* arrays for its `values` field, but not instances of other types:

```
>>> bar.values = (c_byte * 4)()
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: incompatible types, c_byte_Array_4 instance instead of LP_c_long instance
>>>
```

For these cases, the *cast()* function is handy.

The *cast()* function can be used to cast a ctypes instance into a pointer to a different ctypes data type. *cast()* takes two parameters, a ctypes object that is or can be converted to a pointer of some kind, and a ctypes pointer type. It returns an instance of the second argument, which references the same memory block as the first argument:

```
>>> a = (c_byte * 4)()
>>> cast(a, POINTER(c_int))
<ctypes.LP_c_long object at ...>
>>>
```

So, *cast()* can be used to assign to the `values` field of `Bar` the structure:

```
>>> bar = Bar()
>>> bar.values = cast((c_byte * 4)(), POINTER(c_int))
>>> print(bar.values[0])
0
>>>
```

Incomplete Types

Incomplete Types are structures, unions or arrays whose members are not yet specified. In C, they are specified by forward declarations, which are defined later:

```
struct cell; /* forward declaration */

struct cell {
    char *name;
    struct cell *next;
};
```

The straightforward translation into ctypes code would be this, but it does not work:

```
>>> class cell(Structure):
...     _fields_ = [("name", c_char_p),
...                 ("next", POINTER(cell))]
...
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "<stdin>", line 2, in cell
NameError: name 'cell' is not defined
>>>
```

because the new `class cell` is not available in the class statement itself. In *ctypes*, we can define the `cell` class and set the `_fields_` attribute later, after the class statement:

```
>>> from ctypes import *
>>> class cell(Structure):
...     pass
...
>>> cell._fields_ = [("name", c_char_p),
...                  ("next", POINTER(cell))]
>>>
```

Lets try it. We create two instances of `cell`, and let them point to each other, and finally follow the pointer chain a few times:

```
>>> c1 = cell()
>>> c1.name = "foo"
>>> c2 = cell()
>>> c2.name = "bar"
>>> c1.next = pointer(c2)
```

(continues on next page)

(continued from previous page)

```
>>> c2.next = pointer(c1)
>>> p = c1
>>> for i in range(8):
...     print(p.name, end=" ")
...     p = p.next[0]
...
foo bar foo bar foo bar foo bar
>>>
```

Callback functions

ctypes allows creating C callable function pointers from Python callables. These are sometimes called *callback functions*.

First, you must create a class for the callback function. The class knows the calling convention, the return type, and the number and types of arguments this function will receive.

The *CFUNCTYPE()* factory function creates types for callback functions using the `cdecl` calling convention. On Windows, the *WINFUNCTYPE()* factory function creates types for callback functions using the `stdcall` calling convention.

Both of these factory functions are called with the result type as first argument, and the callback functions expected argument types as the remaining arguments.

I will present an example here which uses the standard C library's `qsort()` function, that is used to sort items with the help of a callback function. `qsort()` will be used to sort an array of integers:

```
>>> IntArray5 = c_int * 5
>>> ia = IntArray5(5, 1, 7, 33, 99)
>>> qsort = libc.qsort
>>> qsort.restype = None
>>>
```

`qsort()` must be called with a pointer to the data to sort, the number of items in the data array, the size of one item, and a pointer to the comparison function, the callback. The callback will then be called with two pointers to items, and it must return a negative integer if the first item is smaller than the second, a zero if they are equal, and a positive integer otherwise.

So our callback function receives pointers to integers, and must return an integer. First we create the `type` for the callback function:

```
>>> CMPFUNC = CFUNCTYPE(c_int, POINTER(c_int), POINTER(c_int))
>>>
```

To get started, here is a simple callback that shows the values it gets passed:

```
>>> def py_cmp_func(a, b):
...     print("py_cmp_func", a[0], b[0])
...     return 0
...
>>> cmp_func = CMPFUNC(py_cmp_func)
>>>
```

The result:

```
>>> qsort(ia, len(ia), sizeof(c_int), cmp_func)
py_cmp_func 5 1
py_cmp_func 33 99
py_cmp_func 7 33
py_cmp_func 5 7
py_cmp_func 1 7
>>>
```

Now we can actually compare the two items and return a useful result:

```
>>> def py_cmp_func(a, b):
...     print("py_cmp_func", a[0], b[0])
...     return a[0] - b[0]
...
>>>
>>> qsort(ia, len(ia), sizeof(c_int), CMPFUNC(py_cmp_func))
py_cmp_func 5 1
py_cmp_func 33 99
py_cmp_func 7 33
py_cmp_func 1 7
py_cmp_func 5 7
>>>
```

As we can easily check, our array is sorted now:

```
>>> for i in ia: print(i, end=" ")
...
1 5 7 33 99
>>>
```

Note: Make sure you keep references to *CFUNCTYPE()* objects as long as they are used from C code. *ctypes* doesn't, and if you don't, they may be garbage collected, crashing your program when a callback is made.

Also, note that if the callback function is called in a thread created outside of Python's control (e.g. by the foreign code that calls the callback), ctypes creates a new dummy Python thread on every invocation. This behavior is correct for most purposes, but it means that values stored with *threading.local* will *not* survive across different callbacks, even when those calls are made from the same C thread.

Accessing values exported from dlls

Some shared libraries not only export functions, they also export variables. An example in the Python library itself is the `Py_OptimizeFlag`, an integer set to 0, 1, or 2, depending on the `-O` or `-OO` flag given on startup.

ctypes can access values like this with the `in_dll()` class methods of the type. *pythonapi* is a predefined symbol giving access to the Python C api:

```
>>> opt_flag = c_int.in_dll(pythonapi, "Py_OptimizeFlag")
>>> print(opt_flag)
c_long(0)
>>>
```

If the interpreter would have been started with `-O`, the sample would have printed `c_long(1)`, or `c_long(2)` if `-OO` would have been specified.

An extended example which also demonstrates the use of pointers accesses the `PyImport_FrozenModules` pointer exported by Python.

Quoting the docs for that value:

> This pointer is initialized to point to an array of `struct _frozen` records, terminated by one whose members are all *NULL* or zero. When a frozen module is imported, it is searched in this table. Third-party code could play tricks with this to provide a dynamically created collection of frozen modules.

So manipulating this pointer could even prove useful. To restrict the example size, we show only how this table can be read with *ctypes*:

```
>>> from ctypes import *
>>>
>>> class struct_frozen(Structure):
...     _fields_ = [("name", c_char_p),
...                 ("code", POINTER(c_ubyte)),
...                 ("size", c_int)]
...
>>>
```

We have defined the `struct _frozen` data type, so we can get the pointer to the table:

```
>>> FrozenTable = POINTER(struct_frozen)
>>> table = FrozenTable.in_dll(pythonapi, "PyImport_FrozenModules")
>>>
```

Since `table` is a `pointer` to the array of `struct_frozen` records, we can iterate over it, but we just have to make sure that our loop terminates, because pointers have no size. Sooner or later it would probably crash with an access violation or whatever, so it's better to break out of the loop when we hit the NULL entry:

```
>>> for item in table:
...     if item.name is None:
...         break
...     print(item.name.decode("ascii"), item.size)
...
_frozen_importlib 31764
_frozen_importlib_external 41499
__hello__ 161
__phello__ -161
__phello__.spam 161
>>>
```

The fact that standard Python has a frozen module and a frozen package (indicated by the negative size member) is not well known, it is only used for testing. Try it out with `import __hello__` for example.

Surprises

There are some edges in *ctypes* where you might expect something other than what actually happens.

Consider the following example:

```
>>> from ctypes import *
>>> class POINT(Structure):
...     _fields_ = ("x", c_int), ("y", c_int)
...
>>> class RECT(Structure):
```

(continues on next page)

(continued from previous page)

```
...     _fields_ = ("a", POINT), ("b", POINT)
...
>>> p1 = POINT(1, 2)
>>> p2 = POINT(3, 4)
>>> rc = RECT(p1, p2)
>>> print(rc.a.x, rc.a.y, rc.b.x, rc.b.y)
1 2 3 4
>>> # now swap the two points
>>> rc.a, rc.b = rc.b, rc.a
>>> print(rc.a.x, rc.a.y, rc.b.x, rc.b.y)
3 4 3 4
>>>
```

Hm. We certainly expected the last statement to print `3 4 1 2`. What happened? Here are the steps of the `rc.a, rc.b = rc.b, rc.a` line above:

```
>>> temp0, temp1 = rc.b, rc.a
>>> rc.a = temp0
>>> rc.b = temp1
>>>
```

Note that `temp0` and `temp1` are objects still using the internal buffer of the `rc` object above. So executing `rc.a = temp0` copies the buffer contents of `temp0` into `rc` 's buffer. This, in turn, changes the contents of `temp1`. So, the last assignment `rc.b = temp1`, doesn't have the expected effect.

Keep in mind that retrieving sub-objects from Structure, Unions, and Arrays doesn't *copy* the sub-object, instead it retrieves a wrapper object accessing the root-object's underlying buffer.

Another example that may behave different from what one would expect is this:

```
>>> s = c_char_p()
>>> s.value = "abc def ghi"
>>> s.value
'abc def ghi'
>>> s.value is s.value
False
>>>
```

Why is it printing `False`? ctypes instances are objects containing a memory block plus some *descriptor*s accessing the contents of the memory. Storing a Python object in the memory block does not store the object itself, instead the `contents` of the object is stored. Accessing the contents again constructs a new Python object each time!

Variable-sized data types

ctypes provides some support for variable-sized arrays and structures.

The *resize()* function can be used to resize the memory buffer of an existing ctypes object. The function takes the object as first argument, and the requested size in bytes as the second argument. The memory block cannot be made smaller than the natural memory block specified by the objects type, a *ValueError* is raised if this is tried:

```
>>> short_array = (c_short * 4)()
>>> print(sizeof(short_array))
8
>>> resize(short_array, 4)
```

(continues on next page)

(continued from previous page)

```
Traceback (most recent call last):
    ...
ValueError: minimum size is 8
>>> resize(short_array, 32)
>>> sizeof(short_array)
32
>>> sizeof(type(short_array))
8
>>>
```

This is nice and fine, but how would one access the additional elements contained in this array? Since the type still only knows about 4 elements, we get errors accessing other elements:

```
>>> short_array[:]
[0, 0, 0, 0]
>>> short_array[7]
Traceback (most recent call last):
    ...
IndexError: invalid index
>>>
```

Another way to use variable-sized data types with *ctypes* is to use the dynamic nature of Python, and (re-)define the data type after the required size is already known, on a case by case basis.

16.16.2 ctypes reference

Finding shared libraries

When programming in a compiled language, shared libraries are accessed when compiling/linking a program, and when the program is run.

The purpose of the `find_library()` function is to locate a library in a way similar to what the compiler or runtime loader does (on platforms with several versions of a shared library the most recent should be loaded), while the ctypes library loaders act like when a program is run, and call the runtime loader directly.

The `ctypes.util` module provides a function which can help to determine the library to load.

`ctypes.util.find_library(`*name*`)`

Try to find a library and return a pathname. *name* is the library name without any prefix like *lib*, suffix like `.so`, `.dylib` or version number (this is the form used for the posix linker option `-l`). If no library can be found, returns `None`.

The exact functionality is system dependent.

On Linux, `find_library()` tries to run external programs (`/sbin/ldconfig`, `gcc`, `objdump` and `ld`) to find the library file. It returns the filename of the library file.

Changed in version 3.6: On Linux, the value of the environment variable `LD_LIBRARY_PATH` is used when searching for libraries, if a library cannot be found by any other means.

Here are some examples:

```
>>> from ctypes.util import find_library
>>> find_library("m")
'libm.so.6'
>>> find_library("c")
'libc.so.6'
```

(continues on next page)

(continued from previous page)

```
>>> find_library("bz2")
'libbz2.so.1.0'
>>>
```

On OS X, `find_library()` tries several predefined naming schemes and paths to locate the library, and returns a full pathname if successful:

```
>>> from ctypes.util import find_library
>>> find_library("c")
'/usr/lib/libc.dylib'
>>> find_library("m")
'/usr/lib/libm.dylib'
>>> find_library("bz2")
'/usr/lib/libbz2.dylib'
>>> find_library("AGL")
'/System/Library/Frameworks/AGL.framework/AGL'
>>>
```

On Windows, `find_library()` searches along the system search path, and returns the full pathname, but since there is no predefined naming scheme a call like `find_library("c")` will fail and return `None`.

If wrapping a shared library with *ctypes*, it *may* be better to determine the shared library name at development time, and hardcode that into the wrapper module instead of using `find_library()` to locate the library at runtime.

Loading shared libraries

There are several ways to load shared libraries into the Python process. One way is to instantiate one of the following classes:

class ctypes.CDLL(*name*, *mode=DEFAULT_MODE*, *handle=None*, *use_errno=False*, *use_last_error=False*)

Instances of this class represent loaded shared libraries. Functions in these libraries use the standard C calling convention, and are assumed to return `int`.

class ctypes.OleDLL(*name*, *mode=DEFAULT_MODE*, *handle=None*, *use_errno=False*, *use_last_error=False*)

Windows only: Instances of this class represent loaded shared libraries, functions in these libraries use the `stdcall` calling convention, and are assumed to return the windows specific *HRESULT* code. *HRESULT* values contain information specifying whether the function call failed or succeeded, together with additional error code. If the return value signals a failure, an *OSError* is automatically raised.

Changed in version 3.3: *WindowsError* used to be raised.

class ctypes.WinDLL(*name*, *mode=DEFAULT_MODE*, *handle=None*, *use_errno=False*, *use_last_error=False*)

Windows only: Instances of this class represent loaded shared libraries, functions in these libraries use the `stdcall` calling convention, and are assumed to return `int` by default.

On Windows CE only the standard calling convention is used, for convenience the *WinDLL* and *OleDLL* use the standard calling convention on this platform.

The Python *global interpreter lock* is released before calling any function exported by these libraries, and reacquired afterwards.

class ctypes.PyDLL(*name*, *mode=DEFAULT_MODE*, *handle=None*)

Instances of this class behave like *CDLL* instances, except that the Python GIL is *not* released during the function call, and after the function execution the Python error flag is checked. If the error flag is set, a Python exception is raised.

Thus, this is only useful to call Python C api functions directly.

All these classes can be instantiated by calling them with at least one argument, the pathname of the shared library. If you have an existing handle to an already loaded shared library, it can be passed as the `handle` named parameter, otherwise the underlying platforms `dlopen` or `LoadLibrary` function is used to load the library into the process, and to get a handle to it.

The *mode* parameter can be used to specify how the library is loaded. For details, consult the *dlopen(3)* manpage. On Windows, *mode* is ignored. On posix systems, RTLD_NOW is always added, and is not configurable.

The *use_errno* parameter, when set to true, enables a ctypes mechanism that allows accessing the system *errno* error number in a safe way. *ctypes* maintains a thread-local copy of the systems *errno* variable; if you call foreign functions created with `use_errno=True` then the *errno* value before the function call is swapped with the ctypes private copy, the same happens immediately after the function call.

The function *ctypes.get_errno()* returns the value of the ctypes private copy, and the function *ctypes.set_errno()* changes the ctypes private copy to a new value and returns the former value.

The *use_last_error* parameter, when set to true, enables the same mechanism for the Windows error code which is managed by the *GetLastError()* and `SetLastError()` Windows API functions; *ctypes.get_last_error()* and *ctypes.set_last_error()* are used to request and change the ctypes private copy of the windows error code.

`ctypes.RTLD_GLOBAL`
: Flag to use as *mode* parameter. On platforms where this flag is not available, it is defined as the integer zero.

`ctypes.RTLD_LOCAL`
: Flag to use as *mode* parameter. On platforms where this is not available, it is the same as *RTLD_GLOBAL*.

`ctypes.DEFAULT_MODE`
: The default mode which is used to load shared libraries. On OSX 10.3, this is *RTLD_GLOBAL*, otherwise it is the same as *RTLD_LOCAL*.

Instances of these classes have no public methods. Functions exported by the shared library can be accessed as attributes or by index. Please note that accessing the function through an attribute caches the result and therefore accessing it repeatedly returns the same object each time. On the other hand, accessing it through an index returns a new object each time:

```
>>> from ctypes import CDLL
>>> libc = CDLL("libc.so.6")  # On Linux
>>> libc.time == libc.time
True
>>> libc['time'] == libc['time']
False
```

The following public attributes are available, their name starts with an underscore to not clash with exported function names:

`PyDLL._handle`
: The system handle used to access the library.

`PyDLL._name`
: The name of the library passed in the constructor.

Shared libraries can also be loaded by using one of the prefabricated objects, which are instances of the *LibraryLoader* class, either by calling the `LoadLibrary()` method, or by retrieving the library as attribute of the loader instance.

class ctypes.LibraryLoader(*dlltype*)
Class which loads shared libraries. *dlltype* should be one of the *CDLL*, *PyDLL*, *WinDLL*, or *OleDLL* types.

__getattr__() has special behavior: It allows loading a shared library by accessing it as attribute of a library loader instance. The result is cached, so repeated attribute accesses return the same library each time.

LoadLibrary(*name*)
Load a shared library into the process and return it. This method always returns a new instance of the library.

These prefabricated library loaders are available:

ctypes.cdll
Creates *CDLL* instances.

ctypes.windll
Windows only: Creates *WinDLL* instances.

ctypes.oledll
Windows only: Creates *OleDLL* instances.

ctypes.pydll
Creates *PyDLL* instances.

For accessing the C Python api directly, a ready-to-use Python shared library object is available:

ctypes.pythonapi
An instance of *PyDLL* that exposes Python C API functions as attributes. Note that all these functions are assumed to return C **int**, which is of course not always the truth, so you have to assign the correct **restype** attribute to use these functions.

Foreign functions

As explained in the previous section, foreign functions can be accessed as attributes of loaded shared libraries. The function objects created in this way by default accept any number of arguments, accept any ctypes data instances as arguments, and return the default result type specified by the library loader. They are instances of a private class:

class ctypes._FuncPtr
Base class for C callable foreign functions.

Instances of foreign functions are also C compatible data types; they represent C function pointers.

This behavior can be customized by assigning to special attributes of the foreign function object.

restype
Assign a ctypes type to specify the result type of the foreign function. Use **None** for **void**, a function not returning anything.

It is possible to assign a callable Python object that is not a ctypes type, in this case the function is assumed to return a C **int**, and the callable will be called with this integer, allowing further processing or error checking. Using this is deprecated, for more flexible post processing or error checking use a ctypes data type as *restype* and assign a callable to the *errcheck* attribute.

argtypes
Assign a tuple of ctypes types to specify the argument types that the function accepts. Functions using the **stdcall** calling convention can only be called with the same number of arguments as the length of this tuple; functions using the C calling convention accept additional, unspecified arguments as well.

When a foreign function is called, each actual argument is passed to the **from_param()** class method of the items in the *argtypes* tuple, this method allows adapting the actual argument to

an object that the foreign function accepts. For example, a *c_char_p* item in the *argtypes* tuple will convert a string passed as argument into a bytes object using ctypes conversion rules.

New: It is now possible to put items in argtypes which are not ctypes types, but each item must have a `from_param()` method which returns a value usable as argument (integer, string, ctypes instance). This allows defining adapters that can adapt custom objects as function parameters.

errcheck
Assign a Python function or another callable to this attribute. The callable will be called with three or more arguments:

callable(*result*, *func*, *arguments*)
result is what the foreign function returns, as specified by the `restype` attribute.

func is the foreign function object itself, this allows reusing the same callable object to check or post process the results of several functions.

arguments is a tuple containing the parameters originally passed to the function call, this allows specializing the behavior on the arguments used.

The object that this function returns will be returned from the foreign function call, but it can also check the result value and raise an exception if the foreign function call failed.

exception ctypes.ArgumentError
This exception is raised when a foreign function call cannot convert one of the passed arguments.

Function prototypes

Foreign functions can also be created by instantiating function prototypes. Function prototypes are similar to function prototypes in C; they describe a function (return type, argument types, calling convention) without defining an implementation. The factory functions must be called with the desired result type and the argument types of the function.

ctypes.CFUNCTYPE(*restype*, **argtypes*, *use_errno=False*, *use_last_error=False*)
The returned function prototype creates functions that use the standard C calling convention. The function will release the GIL during the call. If *use_errno* is set to true, the ctypes private copy of the system *errno* variable is exchanged with the real *errno* value before and after the call; *use_last_error* does the same for the Windows error code.

ctypes.WINFUNCTYPE(*restype*, **argtypes*, *use_errno=False*, *use_last_error=False*)
Windows only: The returned function prototype creates functions that use the `stdcall` calling convention, except on Windows CE where *WINFUNCTYPE()* is the same as *CFUNCTYPE()*. The function will release the GIL during the call. *use_errno* and *use_last_error* have the same meaning as above.

ctypes.PYFUNCTYPE(*restype*, **argtypes*)
The returned function prototype creates functions that use the Python calling convention. The function will *not* release the GIL during the call.

Function prototypes created by these factory functions can be instantiated in different ways, depending on the type and number of the parameters in the call:

prototype(*address*)
Returns a foreign function at the specified address which must be an integer.

prototype(*callable*)
Create a C callable function (a callback function) from a Python *callable*.

prototype(*func_spec*[, *paramflags*])
Returns a foreign function exported by a shared library. *func_spec* must be a 2-tuple `(name_or_ordinal, library)`. The first item is the name of the exported function as

string, or the ordinal of the exported function as small integer. The second item is the shared library instance.

prototype(*vtbl_index*, *name*[, *paramflags*[, *iid*]])
Returns a foreign function that will call a COM method. *vtbl_index* is the index into the virtual function table, a small non-negative integer. *name* is name of the COM method. *iid* is an optional pointer to the interface identifier which is used in extended error reporting.

COM methods use a special calling convention: They require a pointer to the COM interface as first argument, in addition to those parameters that are specified in the `argtypes` tuple.

The optional *paramflags* parameter creates foreign function wrappers with much more functionality than the features described above.

paramflags must be a tuple of the same length as `argtypes`.

Each item in this tuple contains further information about a parameter, it must be a tuple containing one, two, or three items.

The first item is an integer containing a combination of direction flags for the parameter:

1 Specifies an input parameter to the function.

2 Output parameter. The foreign function fills in a value.

4 Input parameter which defaults to the integer zero.

The optional second item is the parameter name as string. If this is specified, the foreign function can be called with named parameters.

The optional third item is the default value for this parameter.

This example demonstrates how to wrap the Windows `MessageBoxW` function so that it supports default parameters and named arguments. The C declaration from the windows header file is this:

```
WINUSERAPI int WINAPI
MessageBoxW(
    HWND hWnd,
    LPCWSTR lpText,
    LPCWSTR lpCaption,
    UINT uType);
```

Here is the wrapping with *ctypes*:

```
>>> from ctypes import c_int, WINFUNCTYPE, windll
>>> from ctypes.wintypes import HWND, LPCWSTR, UINT
>>> prototype = WINFUNCTYPE(c_int, HWND, LPCWSTR, LPCWSTR, UINT)
>>> paramflags = (1, "hwnd", 0), (1, "text", "Hi"), (1, "caption", "Hello from ctypes"), (1, "flags
↪", 0)
>>> MessageBox = prototype(("MessageBoxW", windll.user32), paramflags)
```

The `MessageBox` foreign function can now be called in these ways:

```
>>> MessageBox()
>>> MessageBox(text="Spam, spam, spam")
>>> MessageBox(flags=2, text="foo bar")
```

A second example demonstrates output parameters. The win32 `GetWindowRect` function retrieves the dimensions of a specified window by copying them into `RECT` structure that the caller has to supply. Here is the C declaration:

```
WINUSERAPI BOOL WINAPI
GetWindowRect(
     HWND hWnd,
     LPRECT lpRect);
```

Here is the wrapping with *ctypes*:

```
>>> from ctypes import POINTER, WINFUNCTYPE, windll, WinError
>>> from ctypes.wintypes import BOOL, HWND, RECT
>>> prototype = WINFUNCTYPE(BOOL, HWND, POINTER(RECT))
>>> paramflags = (1, "hwnd"), (2, "lprect")
>>> GetWindowRect = prototype(("GetWindowRect", windll.user32), paramflags)
>>>
```

Functions with output parameters will automatically return the output parameter value if there is a single one, or a tuple containing the output parameter values when there are more than one, so the GetWindowRect function now returns a RECT instance, when called.

Output parameters can be combined with the `errcheck` protocol to do further output processing and error checking. The win32 `GetWindowRect` api function returns a `BOOL` to signal success or failure, so this function could do the error checking, and raises an exception when the api call failed:

```
>>> def errcheck(result, func, args):
...     if not result:
...         raise WinError()
...     return args
...
>>> GetWindowRect.errcheck = errcheck
>>>
```

If the `errcheck` function returns the argument tuple it receives unchanged, *ctypes* continues the normal processing it does on the output parameters. If you want to return a tuple of window coordinates instead of a `RECT` instance, you can retrieve the fields in the function and return them instead, the normal processing will no longer take place:

```
>>> def errcheck(result, func, args):
...     if not result:
...         raise WinError()
...     rc = args[1]
...     return rc.left, rc.top, rc.bottom, rc.right
...
>>> GetWindowRect.errcheck = errcheck
>>>
```

Utility functions

`ctypes.addressof(`*obj*`)`
: Returns the address of the memory buffer as integer. *obj* must be an instance of a ctypes type.

`ctypes.alignment(`*obj_or_type*`)`
: Returns the alignment requirements of a ctypes type. *obj_or_type* must be a ctypes type or instance.

`ctypes.byref(`*obj*[, *offset*]`)`
: Returns a light-weight pointer to *obj*, which must be an instance of a ctypes type. *offset* defaults to zero, and must be an integer that will be added to the internal pointer value.

  `byref(obj, offset)` corresponds to this C code:

```
(((char *)&obj) + offset)
```

The returned object can only be used as a foreign function call parameter. It behaves similar to `pointer(obj)`, but the construction is a lot faster.

`ctypes.cast(`*obj*, *type*`)`
This function is similar to the cast operator in C. It returns a new instance of *type* which points to the same memory block as *obj*. *type* must be a pointer type, and *obj* must be an object that can be interpreted as a pointer.

`ctypes.create_string_buffer(`*init_or_size*, *size=None*`)`
This function creates a mutable character buffer. The returned object is a ctypes array of *c_char*.

init_or_size must be an integer which specifies the size of the array, or a bytes object which will be used to initialize the array items.

If a bytes object is specified as first argument, the buffer is made one item larger than its length so that the last element in the array is a NUL termination character. An integer can be passed as second argument which allows specifying the size of the array if the length of the bytes should not be used.

`ctypes.create_unicode_buffer(`*init_or_size*, *size=None*`)`
This function creates a mutable unicode character buffer. The returned object is a ctypes array of *c_wchar*.

init_or_size must be an integer which specifies the size of the array, or a string which will be used to initialize the array items.

If a string is specified as first argument, the buffer is made one item larger than the length of the string so that the last element in the array is a NUL termination character. An integer can be passed as second argument which allows specifying the size of the array if the length of the string should not be used.

`ctypes.DllCanUnloadNow()`
Windows only: This function is a hook which allows implementing in-process COM servers with ctypes. It is called from the DllCanUnloadNow function that the _ctypes extension dll exports.

`ctypes.DllGetClassObject()`
Windows only: This function is a hook which allows implementing in-process COM servers with ctypes. It is called from the DllGetClassObject function that the `_ctypes` extension dll exports.

`ctypes.util.find_library(`*name*`)`
Try to find a library and return a pathname. *name* is the library name without any prefix like `lib`, suffix like `.so`, `.dylib` or version number (this is the form used for the posix linker option `-l`). If no library can be found, returns `None`.

The exact functionality is system dependent.

`ctypes.util.find_msvcrt()`
Windows only: return the filename of the VC runtime library used by Python, and by the extension modules. If the name of the library cannot be determined, `None` is returned.

If you need to free memory, for example, allocated by an extension module with a call to the `free(void *)`, it is important that you use the function in the same library that allocated the memory.

`ctypes.FormatError(`[*code*]`)`
Windows only: Returns a textual description of the error code *code*. If no error code is specified, the last error code is used by calling the Windows api function GetLastError.

`ctypes.GetLastError()`
Windows only: Returns the last error code set by Windows in the calling thread. This function calls the Windows *GetLastError()* function directly, it does not return the ctypes-private copy of the error code.

ctypes.**get_errno**()
Returns the current value of the ctypes-private copy of the system *errno* variable in the calling thread.

ctypes.**get_last_error**()
Windows only: returns the current value of the ctypes-private copy of the system `LastError` variable in the calling thread.

ctypes.**memmove**(*dst*, *src*, *count*)
Same as the standard C memmove library function: copies *count* bytes from *src* to *dst*. *dst* and *src* must be integers or ctypes instances that can be converted to pointers.

ctypes.**memset**(*dst*, *c*, *count*)
Same as the standard C memset library function: fills the memory block at address *dst* with *count* bytes of value *c*. *dst* must be an integer specifying an address, or a ctypes instance.

ctypes.**POINTER**(*type*)
This factory function creates and returns a new ctypes pointer type. Pointer types are cached and reused internally, so calling this function repeatedly is cheap. *type* must be a ctypes type.

ctypes.**pointer**(*obj*)
This function creates a new pointer instance, pointing to *obj*. The returned object is of the type `POINTER(type(obj))`.

Note: If you just want to pass a pointer to an object to a foreign function call, you should use `byref(obj)` which is much faster.

ctypes.**resize**(*obj*, *size*)
This function resizes the internal memory buffer of *obj*, which must be an instance of a ctypes type. It is not possible to make the buffer smaller than the native size of the objects type, as given by `sizeof(type(obj))`, but it is possible to enlarge the buffer.

ctypes.**set_errno**(*value*)
Set the current value of the ctypes-private copy of the system *errno* variable in the calling thread to *value* and return the previous value.

ctypes.**set_last_error**(*value*)
Windows only: set the current value of the ctypes-private copy of the system `LastError` variable in the calling thread to *value* and return the previous value.

ctypes.**sizeof**(*obj_or_type*)
Returns the size in bytes of a ctypes type or instance memory buffer. Does the same as the C `sizeof` operator.

ctypes.**string_at**(*address*, *size=-1*)
This function returns the C string starting at memory address *address* as a bytes object. If size is specified, it is used as size, otherwise the string is assumed to be zero-terminated.

ctypes.**WinError**(*code=None*, *descr=None*)
Windows only: this function is probably the worst-named thing in ctypes. It creates an instance of OSError. If *code* is not specified, `GetLastError` is called to determine the error code. If *descr* is not specified, *FormatError()* is called to get a textual description of the error.

Changed in version 3.3: An instance of *WindowsError* used to be created.

ctypes.**wstring_at**(*address*, *size=-1*)
This function returns the wide character string starting at memory address *address* as a string. If *size* is specified, it is used as the number of characters of the string, otherwise the string is assumed to be zero-terminated.

Data types

class ctypes._CData

This non-public class is the common base class of all ctypes data types. Among other things, all ctypes type instances contain a memory block that hold C compatible data; the address of the memory block is returned by the *addressof()* helper function. Another instance variable is exposed as *_objects*; this contains other Python objects that need to be kept alive in case the memory block contains pointers.

Common methods of ctypes data types, these are all class methods (to be exact, they are methods of the *metaclass*):

from_buffer(*source*[, *offset*])

This method returns a ctypes instance that shares the buffer of the *source* object. The *source* object must support the writeable buffer interface. The optional *offset* parameter specifies an offset into the source buffer in bytes; the default is zero. If the source buffer is not large enough a *ValueError* is raised.

from_buffer_copy(*source*[, *offset*])

This method creates a ctypes instance, copying the buffer from the *source* object buffer which must be readable. The optional *offset* parameter specifies an offset into the source buffer in bytes; the default is zero. If the source buffer is not large enough a *ValueError* is raised.

from_address(*address*)

This method returns a ctypes type instance using the memory specified by *address* which must be an integer.

from_param(*obj*)

This method adapts *obj* to a ctypes type. It is called with the actual object used in a foreign function call when the type is present in the foreign function's **argtypes** tuple; it must return an object that can be used as a function call parameter.

All ctypes data types have a default implementation of this classmethod that normally returns *obj* if that is an instance of the type. Some types accept other objects as well.

in_dll(*library*, *name*)

This method returns a ctypes type instance exported by a shared library. *name* is the name of the symbol that exports the data, *library* is the loaded shared library.

Common instance variables of ctypes data types:

_b_base_

Sometimes ctypes data instances do not own the memory block they contain, instead they share part of the memory block of a base object. The *_b_base_* read-only member is the root ctypes object that owns the memory block.

_b_needsfree_

This read-only variable is true when the ctypes data instance has allocated the memory block itself, false otherwise.

_objects

This member is either **None** or a dictionary containing Python objects that need to be kept alive so that the memory block contents is kept valid. This object is only exposed for debugging; never modify the contents of this dictionary.

Fundamental data types

class ctypes._SimpleCData

This non-public class is the base class of all fundamental ctypes data types. It is mentioned here because it contains the common attributes of the fundamental ctypes data types. *_SimpleCData* is a

subclass of *_CData*, so it inherits their methods and attributes. ctypes data types that are not and do not contain pointers can now be pickled.

Instances have a single attribute:

value
This attribute contains the actual value of the instance. For integer and pointer types, it is an integer, for character types, it is a single character bytes object or string, for character pointer types it is a Python bytes object or string.

When the `value` attribute is retrieved from a ctypes instance, usually a new object is returned each time. *ctypes* does *not* implement original object return, always a new object is constructed. The same is true for all other ctypes object instances.

Fundamental data types, when returned as foreign function call results, or, for example, by retrieving structure field members or array items, are transparently converted to native Python types. In other words, if a foreign function has a `restype` of *c_char_p*, you will always receive a Python bytes object, *not* a *c_char_p* instance.

Subclasses of fundamental data types do *not* inherit this behavior. So, if a foreign functions `restype` is a subclass of *c_void_p*, you will receive an instance of this subclass from the function call. Of course, you can get the value of the pointer by accessing the `value` attribute.

These are the fundamental ctypes data types:

class ctypes.c_byte
Represents the C `signed char` datatype, and interprets the value as small integer. The constructor accepts an optional integer initializer; no overflow checking is done.

class ctypes.c_char
Represents the C `char` datatype, and interprets the value as a single character. The constructor accepts an optional string initializer, the length of the string must be exactly one character.

class ctypes.c_char_p
Represents the C `char *` datatype when it points to a zero-terminated string. For a general character pointer that may also point to binary data, `POINTER(c_char)` must be used. The constructor accepts an integer address, or a bytes object.

class ctypes.c_double
Represents the C `double` datatype. The constructor accepts an optional float initializer.

class ctypes.c_longdouble
Represents the C `long double` datatype. The constructor accepts an optional float initializer. On platforms where `sizeof(long double) == sizeof(double)` it is an alias to *c_double*.

class ctypes.c_float
Represents the C `float` datatype. The constructor accepts an optional float initializer.

class ctypes.c_int
Represents the C `signed int` datatype. The constructor accepts an optional integer initializer; no overflow checking is done. On platforms where `sizeof(int) == sizeof(long)` it is an alias to *c_long*.

class ctypes.c_int8
Represents the C 8-bit `signed int` datatype. Usually an alias for *c_byte*.

class ctypes.c_int16
Represents the C 16-bit `signed int` datatype. Usually an alias for *c_short*.

class ctypes.c_int32
Represents the C 32-bit `signed int` datatype. Usually an alias for *c_int*.

class ctypes.c_int64
Represents the C 64-bit `signed int` datatype. Usually an alias for *c_longlong*.

class ctypes.c_long
Represents the C `signed long` datatype. The constructor accepts an optional integer initializer; no overflow checking is done.

class ctypes.c_longlong
Represents the C `signed long long` datatype. The constructor accepts an optional integer initializer; no overflow checking is done.

class ctypes.c_short
Represents the C `signed short` datatype. The constructor accepts an optional integer initializer; no overflow checking is done.

class ctypes.c_size_t
Represents the C `size_t` datatype.

class ctypes.c_ssize_t
Represents the C `ssize_t` datatype.

New in version 3.2.

class ctypes.c_ubyte
Represents the C `unsigned char` datatype, it interprets the value as small integer. The constructor accepts an optional integer initializer; no overflow checking is done.

class ctypes.c_uint
Represents the C `unsigned int` datatype. The constructor accepts an optional integer initializer; no overflow checking is done. On platforms where `sizeof(int) == sizeof(long)` it is an alias for *c_ulong*.

class ctypes.c_uint8
Represents the C 8-bit `unsigned int` datatype. Usually an alias for *c_ubyte*.

class ctypes.c_uint16
Represents the C 16-bit `unsigned int` datatype. Usually an alias for *c_ushort*.

class ctypes.c_uint32
Represents the C 32-bit `unsigned int` datatype. Usually an alias for *c_uint*.

class ctypes.c_uint64
Represents the C 64-bit `unsigned int` datatype. Usually an alias for *c_ulonglong*.

class ctypes.c_ulong
Represents the C `unsigned long` datatype. The constructor accepts an optional integer initializer; no overflow checking is done.

class ctypes.c_ulonglong
Represents the C `unsigned long long` datatype. The constructor accepts an optional integer initializer; no overflow checking is done.

class ctypes.c_ushort
Represents the C `unsigned short` datatype. The constructor accepts an optional integer initializer; no overflow checking is done.

class ctypes.c_void_p
Represents the C `void *` type. The value is represented as integer. The constructor accepts an optional integer initializer.

class ctypes.c_wchar
Represents the C `wchar_t` datatype, and interprets the value as a single character unicode string. The constructor accepts an optional string initializer, the length of the string must be exactly one character.

class ctypes.c_wchar_p
Represents the C `wchar_t *` datatype, which must be a pointer to a zero-terminated wide character string. The constructor accepts an integer address, or a string.

class ctypes.c_bool
Represent the C `bool` datatype (more accurately, `_Bool` from C99). Its value can be `True` or `False`, and the constructor accepts any object that has a truth value.

class ctypes.HRESULT
Windows only: Represents a `HRESULT` value, which contains success or error information for a function or method call.

class ctypes.py_object
Represents the C `PyObject *` datatype. Calling this without an argument creates a `NULL PyObject *` pointer.

The `ctypes.wintypes` module provides quite some other Windows specific data types, for example `HWND`, `WPARAM`, or `DWORD`. Some useful structures like `MSG` or `RECT` are also defined.

Structured data types

class ctypes.Union(*args, **kw)
Abstract base class for unions in native byte order.

class ctypes.BigEndianStructure(*args, **kw)
Abstract base class for structures in *big endian* byte order.

class ctypes.LittleEndianStructure(*args, **kw)
Abstract base class for structures in *little endian* byte order.

Structures with non-native byte order cannot contain pointer type fields, or any other data types containing pointer type fields.

class ctypes.Structure(*args, **kw)
Abstract base class for structures in *native* byte order.

Concrete structure and union types must be created by subclassing one of these types, and at least define a *_fields_* class variable. *ctypes* will create *descriptor*s which allow reading and writing the fields by direct attribute accesses. These are the

fields
A sequence defining the structure fields. The items must be 2-tuples or 3-tuples. The first item is the name of the field, the second item specifies the type of the field; it can be any ctypes data type.

For integer type fields like *c_int*, a third optional item can be given. It must be a small positive integer defining the bit width of the field.

Field names must be unique within one structure or union. This is not checked, only one field can be accessed when names are repeated.

It is possible to define the *_fields_* class variable *after* the class statement that defines the Structure subclass, this allows creating data types that directly or indirectly reference themselves:

```
class List(Structure):
    pass
List._fields_ = [("pnext", POINTER(List)),
                 ...
                ]
```

The *_fields_* class variable must, however, be defined before the type is first used (an instance is created, *sizeof()* is called on it, and so on). Later assignments to the *_fields_* class variable will raise an AttributeError.

It is possible to defined sub-subclasses of structure types, they inherit the fields of the base class plus the *_fields_* defined in the sub-subclass, if any.

pack
An optional small integer that allows overriding the alignment of structure fields in the instance. *_pack_* must already be defined when *_fields_* is assigned, otherwise it will have no effect.

anonymous
An optional sequence that lists the names of unnamed (anonymous) fields. *_anonymous_* must be already defined when *_fields_* is assigned, otherwise it will have no effect.

The fields listed in this variable must be structure or union type fields. *ctypes* will create descriptors in the structure type that allows accessing the nested fields directly, without the need to create the structure or union field.

Here is an example type (Windows):

```
class _U(Union):
    _fields_ = [("lptdesc", POINTER(TYPEDESC)),
                ("lpadesc", POINTER(ARRAYDESC)),
                ("hreftype", HREFTYPE)]

class TYPEDESC(Structure):
    _anonymous_ = ("u",)
    _fields_ = [("u", _U),
                ("vt", VARTYPE)]
```

The `TYPEDESC` structure describes a COM data type, the `vt` field specifies which one of the union fields is valid. Since the `u` field is defined as anonymous field, it is now possible to access the members directly off the TYPEDESC instance. `td.lptdesc` and `td.u.lptdesc` are equivalent, but the former is faster since it does not need to create a temporary union instance:

```
td = TYPEDESC()
td.vt = VT_PTR
td.lptdesc = POINTER(some_type)
td.u.lptdesc = POINTER(some_type)
```

It is possible to defined sub-subclasses of structures, they inherit the fields of the base class. If the subclass definition has a separate *_fields_* variable, the fields specified in this are appended to the fields of the base class.

Structure and union constructors accept both positional and keyword arguments. Positional arguments are used to initialize member fields in the same order as they are appear in *_fields_*. Keyword arguments in the constructor are interpreted as attribute assignments, so they will initialize *_fields_* with the same name, or create new attributes for names not present in *_fields_*.

Arrays and pointers

class ctypes.Array(args*)**
Abstract base class for arrays.

The recommended way to create concrete array types is by multiplying any *ctypes* data type with a positive integer. Alternatively, you can subclass this type and define *_length_* and *_type_* class variables. Array elements can be read and written using standard subscript and slice accesses; for slice reads, the resulting object is *not* itself an *Array*.

length
A positive integer specifying the number of elements in the array. Out-of-range subscripts result in an *IndexError*. Will be returned by *len()*.

type
Specifies the type of each element in the array.

Array subclass constructors accept positional arguments, used to initialize the elements in order.

class ctypes._Pointer

Private, abstract base class for pointers.

Concrete pointer types are created by calling *POINTER()* with the type that will be pointed to; this is done automatically by *pointer()*.

If a pointer points to an array, its elements can be read and written using standard subscript and slice accesses. Pointer objects have no size, so *len()* will raise *TypeError*. Negative subscripts will read from the memory *before* the pointer (as in C), and out-of-range subscripts will probably crash with an access violation (if you're lucky).

type

Specifies the type pointed to.

contents

Returns the object to which to pointer points. Assigning to this attribute changes the pointer to point to the assigned object.

CHAPTER

SEVENTEEN

CONCURRENT EXECUTION

The modules described in this chapter provide support for concurrent execution of code. The appropriate choice of tool will depend on the task to be executed (CPU bound vs IO bound) and preferred style of development (event driven cooperative multitasking vs preemptive multitasking). Here's an overview:

17.1 `threading` — Thread-based parallelism

Source code: Lib/threading.py

This module constructs higher-level threading interfaces on top of the lower level *`_thread`* module. See also the *`queue`* module.

Changed in version 3.7: This module used to be optional, it is now always available.

Note: While they are not listed below, the `camelCase` names used for some methods and functions in this module in the Python 2.x series are still supported by this module.

This module defines the following functions:

`threading.active_count()`
: Return the number of *`Thread`* objects currently alive. The returned count is equal to the length of the list returned by *`enumerate()`*.

`threading.current_thread()`
: Return the current *`Thread`* object, corresponding to the caller's thread of control. If the caller's thread of control was not created through the *`threading`* module, a dummy thread object with limited functionality is returned.

`threading.get_ident()`
: Return the 'thread identifier' of the current thread. This is a nonzero integer. Its value has no direct meaning; it is intended as a magic cookie to be used e.g. to index a dictionary of thread-specific data. Thread identifiers may be recycled when a thread exits and another thread is created.

  New in version 3.3.

`threading.enumerate()`
: Return a list of all *`Thread`* objects currently alive. The list includes daemonic threads, dummy thread objects created by *`current_thread()`*, and the main thread. It excludes terminated threads and threads that have not yet been started.

`threading.main_thread()`
: Return the main *`Thread`* object. In normal conditions, the main thread is the thread from which the Python interpreter was started.

New in version 3.4.

threading.settrace(*func*)
Set a trace function for all threads started from the *threading* module. The *func* will be passed to *sys.settrace()* for each thread, before its *run()* method is called.

threading.setprofile(*func*)
Set a profile function for all threads started from the *threading* module. The *func* will be passed to *sys.setprofile()* for each thread, before its *run()* method is called.

threading.stack_size([*size*])
Return the thread stack size used when creating new threads. The optional *size* argument specifies the stack size to be used for subsequently created threads, and must be 0 (use platform or configured default) or a positive integer value of at least 32,768 (32 KiB). If *size* is not specified, 0 is used. If changing the thread stack size is unsupported, a *RuntimeError* is raised. If the specified stack size is invalid, a *ValueError* is raised and the stack size is unmodified. 32 KiB is currently the minimum supported stack size value to guarantee sufficient stack space for the interpreter itself. Note that some platforms may have particular restrictions on values for the stack size, such as requiring a minimum stack size > 32 KiB or requiring allocation in multiples of the system memory page size - platform documentation should be referred to for more information (4 KiB pages are common; using multiples of 4096 for the stack size is the suggested approach in the absence of more specific information). Availability: Windows, systems with POSIX threads.

This module also defines the following constant:

threading.TIMEOUT_MAX
The maximum value allowed for the *timeout* parameter of blocking functions (*Lock.acquire()*, *RLock.acquire()*, *Condition.wait()*, etc.). Specifying a timeout greater than this value will raise an *OverflowError*.

New in version 3.2.

This module defines a number of classes, which are detailed in the sections below.

The design of this module is loosely based on Java's threading model. However, where Java makes locks and condition variables basic behavior of every object, they are separate objects in Python. Python's *Thread* class supports a subset of the behavior of Java's Thread class; currently, there are no priorities, no thread groups, and threads cannot be destroyed, stopped, suspended, resumed, or interrupted. The static methods of Java's Thread class, when implemented, are mapped to module-level functions.

All of the methods described below are executed atomically.

17.1.1 Thread-Local Data

Thread-local data is data whose values are thread specific. To manage thread-local data, just create an instance of *local* (or a subclass) and store attributes on it:

```
mydata = threading.local()
mydata.x = 1
```

The instance's values will be different for separate threads.

class threading.local
A class that represents thread-local data.

For more details and extensive examples, see the documentation string of the `_threading_local` module.

17.1.2 Thread Objects

The *Thread* class represents an activity that is run in a separate thread of control. There are two ways to specify the activity: by passing a callable object to the constructor, or by overriding the *run()* method in a subclass. No other methods (except for the constructor) should be overridden in a subclass. In other words, *only* override the `__init__()` and *run()* methods of this class.

Once a thread object is created, its activity must be started by calling the thread's *start()* method. This invokes the *run()* method in a separate thread of control.

Once the thread's activity is started, the thread is considered 'alive'. It stops being alive when its *run()* method terminates – either normally, or by raising an unhandled exception. The *is_alive()* method tests whether the thread is alive.

Other threads can call a thread's *join()* method. This blocks the calling thread until the thread whose *join()* method is called is terminated.

A thread has a name. The name can be passed to the constructor, and read or changed through the *name* attribute.

A thread can be flagged as a "daemon thread". The significance of this flag is that the entire Python program exits when only daemon threads are left. The initial value is inherited from the creating thread. The flag can be set through the *daemon* property or the *daemon* constructor argument.

Note: Daemon threads are abruptly stopped at shutdown. Their resources (such as open files, database transactions, etc.) may not be released properly. If you want your threads to stop gracefully, make them non-daemonic and use a suitable signalling mechanism such as an *Event*.

There is a "main thread" object; this corresponds to the initial thread of control in the Python program. It is not a daemon thread.

There is the possibility that "dummy thread objects" are created. These are thread objects corresponding to "alien threads", which are threads of control started outside the threading module, such as directly from C code. Dummy thread objects have limited functionality; they are always considered alive and daemonic, and cannot be *join()*ed. They are never deleted, since it is impossible to detect the termination of alien threads.

class threading.Thread(*group=None*, *target=None*, *name=None*, *args=()*, *kwargs={}*, ***, *daemon=None*)

This constructor should always be called with keyword arguments. Arguments are:

group should be `None`; reserved for future extension when a `ThreadGroup` class is implemented.

target is the callable object to be invoked by the *run()* method. Defaults to `None`, meaning nothing is called.

name is the thread name. By default, a unique name is constructed of the form "Thread-*N*" where *N* is a small decimal number.

args is the argument tuple for the target invocation. Defaults to `()`.

kwargs is a dictionary of keyword arguments for the target invocation. Defaults to `{}`.

If not `None`, *daemon* explicitly sets whether the thread is daemonic. If `None` (the default), the daemonic property is inherited from the current thread.

If the subclass overrides the constructor, it must make sure to invoke the base class constructor (`Thread.__init__()`) before doing anything else to the thread.

Changed in version 3.3: Added the *daemon* argument.

start()

Start the thread's activity.

It must be called at most once per thread object. It arranges for the object's *run()* method to be invoked in a separate thread of control.

This method will raise a *RuntimeError* if called more than once on the same thread object.

run()
Method representing the thread's activity.

You may override this method in a subclass. The standard *run()* method invokes the callable object passed to the object's constructor as the *target* argument, if any, with sequential and keyword arguments taken from the *args* and *kwargs* arguments, respectively.

join(*timeout=None*)
Wait until the thread terminates. This blocks the calling thread until the thread whose *join()* method is called terminates – either normally or through an unhandled exception – or until the optional timeout occurs.

When the *timeout* argument is present and not `None`, it should be a floating point number specifying a timeout for the operation in seconds (or fractions thereof). As *join()* always returns `None`, you must call *is_alive()* after *join()* to decide whether a timeout happened – if the thread is still alive, the *join()* call timed out.

When the *timeout* argument is not present or `None`, the operation will block until the thread terminates.

A thread can be *join()*ed many times.

join() raises a *RuntimeError* if an attempt is made to join the current thread as that would cause a deadlock. It is also an error to *join()* a thread before it has been started and attempts to do so raise the same exception.

name
A string used for identification purposes only. It has no semantics. Multiple threads may be given the same name. The initial name is set by the constructor.

getName()
setName()
Old getter/setter API for *name*; use it directly as a property instead.

ident
The 'thread identifier' of this thread or `None` if the thread has not been started. This is a nonzero integer. See the *get_ident()* function. Thread identifiers may be recycled when a thread exits and another thread is created. The identifier is available even after the thread has exited.

is_alive()
Return whether the thread is alive.

This method returns `True` just before the *run()* method starts until just after the *run()* method terminates. The module function *enumerate()* returns a list of all alive threads.

daemon
A boolean value indicating whether this thread is a daemon thread (True) or not (False). This must be set before *start()* is called, otherwise *RuntimeError* is raised. Its initial value is inherited from the creating thread; the main thread is not a daemon thread and therefore all threads created in the main thread default to *daemon* = `False`.

The entire Python program exits when no alive non-daemon threads are left.

isDaemon()
setDaemon()
Old getter/setter API for *daemon*; use it directly as a property instead.

CPython implementation detail: In CPython, due to the *Global Interpreter Lock*, only one thread can execute Python code at once (even though certain performance-oriented libraries might overcome this

limitation). If you want your application to make better use of the computational resources of multi-core machines, you are advised to use *multiprocessing* or *concurrent.futures.ProcessPoolExecutor*. However, threading is still an appropriate model if you want to run multiple I/O-bound tasks simultaneously.

17.1.3 Lock Objects

A primitive lock is a synchronization primitive that is not owned by a particular thread when locked. In Python, it is currently the lowest level synchronization primitive available, implemented directly by the *_thread* extension module.

A primitive lock is in one of two states, "locked" or "unlocked". It is created in the unlocked state. It has two basic methods, *acquire()* and *release()*. When the state is unlocked, *acquire()* changes the state to locked and returns immediately. When the state is locked, *acquire()* blocks until a call to *release()* in another thread changes it to unlocked, then the *acquire()* call resets it to locked and returns. The *release()* method should only be called in the locked state; it changes the state to unlocked and returns immediately. If an attempt is made to release an unlocked lock, a *RuntimeError* will be raised.

Locks also support the *context management protocol*.

When more than one thread is blocked in *acquire()* waiting for the state to turn to unlocked, only one thread proceeds when a *release()* call resets the state to unlocked; which one of the waiting threads proceeds is not defined, and may vary across implementations.

All methods are executed atomically.

class threading.Lock

The class implementing primitive lock objects. Once a thread has acquired a lock, subsequent attempts to acquire it block, until it is released; any thread may release it.

Note that `Lock` is actually a factory function which returns an instance of the most efficient version of the concrete Lock class that is supported by the platform.

acquire(*blocking=True*, *timeout=-1*)

Acquire a lock, blocking or non-blocking.

When invoked with the *blocking* argument set to `True` (the default), block until the lock is unlocked, then set it to locked and return `True`.

When invoked with the *blocking* argument set to `False`, do not block. If a call with *blocking* set to `True` would block, return `False` immediately; otherwise, set the lock to locked and return `True`.

When invoked with the floating-point *timeout* argument set to a positive value, block for at most the number of seconds specified by *timeout* and as long as the lock cannot be acquired. A *timeout* argument of `-1` specifies an unbounded wait. It is forbidden to specify a *timeout* when *blocking* is false.

The return value is `True` if the lock is acquired successfully, `False` if not (for example if the *timeout* expired).

Changed in version 3.2: The *timeout* parameter is new.

Changed in version 3.2: Lock acquires can now be interrupted by signals on POSIX.

release()

Release a lock. This can be called from any thread, not only the thread which has acquired the lock.

When the lock is locked, reset it to unlocked, and return. If any other threads are blocked waiting for the lock to become unlocked, allow exactly one of them to proceed.

When invoked on an unlocked lock, a *RuntimeError* is raised.

There is no return value.

17.1.4 RLock Objects

A reentrant lock is a synchronization primitive that may be acquired multiple times by the same thread. Internally, it uses the concepts of "owning thread" and "recursion level" in addition to the locked/unlocked state used by primitive locks. In the locked state, some thread owns the lock; in the unlocked state, no thread owns it.

To lock the lock, a thread calls its *acquire()* method; this returns once the thread owns the lock. To unlock the lock, a thread calls its *release()* method. *acquire()*/*release()* call pairs may be nested; only the final *release()* (the *release()* of the outermost pair) resets the lock to unlocked and allows another thread blocked in *acquire()* to proceed.

Reentrant locks also support the *context management protocol*.

class threading.RLock

This class implements reentrant lock objects. A reentrant lock must be released by the thread that acquired it. Once a thread has acquired a reentrant lock, the same thread may acquire it again without blocking; the thread must release it once for each time it has acquired it.

Note that `RLock` is actually a factory function which returns an instance of the most efficient version of the concrete RLock class that is supported by the platform.

acquire(*blocking=True*, *timeout=-1*)

Acquire a lock, blocking or non-blocking.

When invoked without arguments: if this thread already owns the lock, increment the recursion level by one, and return immediately. Otherwise, if another thread owns the lock, block until the lock is unlocked. Once the lock is unlocked (not owned by any thread), then grab ownership, set the recursion level to one, and return. If more than one thread is blocked waiting until the lock is unlocked, only one at a time will be able to grab ownership of the lock. There is no return value in this case.

When invoked with the *blocking* argument set to true, do the same thing as when called without arguments, and return true.

When invoked with the *blocking* argument set to false, do not block. If a call without an argument would block, return false immediately; otherwise, do the same thing as when called without arguments, and return true.

When invoked with the floating-point *timeout* argument set to a positive value, block for at most the number of seconds specified by *timeout* and as long as the lock cannot be acquired. Return true if the lock has been acquired, false if the timeout has elapsed.

Changed in version 3.2: The *timeout* parameter is new.

release()

Release a lock, decrementing the recursion level. If after the decrement it is zero, reset the lock to unlocked (not owned by any thread), and if any other threads are blocked waiting for the lock to become unlocked, allow exactly one of them to proceed. If after the decrement the recursion level is still nonzero, the lock remains locked and owned by the calling thread.

Only call this method when the calling thread owns the lock. A *RuntimeError* is raised if this method is called when the lock is unlocked.

There is no return value.

17.1.5 Condition Objects

A condition variable is always associated with some kind of lock; this can be passed in or one will be created by default. Passing one in is useful when several condition variables must share the same lock. The lock is part of the condition object: you don't have to track it separately.

A condition variable obeys the *context management protocol*: using the `with` statement acquires the associated lock for the duration of the enclosed block. The *acquire()* and *release()* methods also call the corresponding methods of the associated lock.

Other methods must be called with the associated lock held. The *wait()* method releases the lock, and then blocks until another thread awakens it by calling *notify()* or *notify_all()*. Once awakened, *wait()* re-acquires the lock and returns. It is also possible to specify a timeout.

The *notify()* method wakes up one of the threads waiting for the condition variable, if any are waiting. The *notify_all()* method wakes up all threads waiting for the condition variable.

Note: the *notify()* and *notify_all()* methods don't release the lock; this means that the thread or threads awakened will not return from their *wait()* call immediately, but only when the thread that called *notify()* or *notify_all()* finally relinquishes ownership of the lock.

The typical programming style using condition variables uses the lock to synchronize access to some shared state; threads that are interested in a particular change of state call *wait()* repeatedly until they see the desired state, while threads that modify the state call *notify()* or *notify_all()* when they change the state in such a way that it could possibly be a desired state for one of the waiters. For example, the following code is a generic producer-consumer situation with unlimited buffer capacity:

```
# Consume one item
with cv:
    while not an_item_is_available():
        cv.wait()
    get_an_available_item()

# Produce one item
with cv:
    make_an_item_available()
    cv.notify()
```

The `while` loop checking for the application's condition is necessary because *wait()* can return after an arbitrary long time, and the condition which prompted the *notify()* call may no longer hold true. This is inherent to multi-threaded programming. The *wait_for()* method can be used to automate the condition checking, and eases the computation of timeouts:

```
# Consume an item
with cv:
    cv.wait_for(an_item_is_available)
    get_an_available_item()
```

To choose between *notify()* and *notify_all()*, consider whether one state change can be interesting for only one or several waiting threads. E.g. in a typical producer-consumer situation, adding one item to the buffer only needs to wake up one consumer thread.

class threading.Condition(*lock=None*)

This class implements condition variable objects. A condition variable allows one or more threads to wait until they are notified by another thread.

If the *lock* argument is given and not `None`, it must be a *Lock* or *RLock* object, and it is used as the underlying lock. Otherwise, a new *RLock* object is created and used as the underlying lock.

Changed in version 3.3: changed from a factory function to a class.

acquire(**args*)

Acquire the underlying lock. This method calls the corresponding method on the underlying lock; the return value is whatever that method returns.

release()

Release the underlying lock. This method calls the corresponding method on the underlying lock;

there is no return value.

wait(*timeout=None*)
Wait until notified or until a timeout occurs. If the calling thread has not acquired the lock when this method is called, a *RuntimeError* is raised.

This method releases the underlying lock, and then blocks until it is awakened by a *notify()* or *notify_all()* call for the same condition variable in another thread, or until the optional timeout occurs. Once awakened or timed out, it re-acquires the lock and returns.

When the *timeout* argument is present and not `None`, it should be a floating point number specifying a timeout for the operation in seconds (or fractions thereof).

When the underlying lock is an *RLock*, it is not released using its *release()* method, since this may not actually unlock the lock when it was acquired multiple times recursively. Instead, an internal interface of the *RLock* class is used, which really unlocks it even when it has been recursively acquired several times. Another internal interface is then used to restore the recursion level when the lock is reacquired.

The return value is `True` unless a given *timeout* expired, in which case it is `False`.

Changed in version 3.2: Previously, the method always returned `None`.

wait_for(*predicate*, *timeout=None*)
Wait until a condition evaluates to true. *predicate* should be a callable which result will be interpreted as a boolean value. A *timeout* may be provided giving the maximum time to wait.

This utility method may call *wait()* repeatedly until the predicate is satisfied, or until a timeout occurs. The return value is the last return value of the predicate and will evaluate to `False` if the method timed out.

Ignoring the timeout feature, calling this method is roughly equivalent to writing:

```
while not predicate():
    cv.wait()
```

Therefore, the same rules apply as with *wait()*: The lock must be held when called and is re-acquired on return. The predicate is evaluated with the lock held.

New in version 3.2.

notify(*n=1*)
By default, wake up one thread waiting on this condition, if any. If the calling thread has not acquired the lock when this method is called, a *RuntimeError* is raised.

This method wakes up at most *n* of the threads waiting for the condition variable; it is a no-op if no threads are waiting.

The current implementation wakes up exactly *n* threads, if at least *n* threads are waiting. However, it's not safe to rely on this behavior. A future, optimized implementation may occasionally wake up more than *n* threads.

Note: an awakened thread does not actually return from its *wait()* call until it can reacquire the lock. Since *notify()* does not release the lock, its caller should.

notify_all()
Wake up all threads waiting on this condition. This method acts like *notify()*, but wakes up all waiting threads instead of one. If the calling thread has not acquired the lock when this method is called, a *RuntimeError* is raised.

17.1.6 Semaphore Objects

This is one of the oldest synchronization primitives in the history of computer science, invented by the early Dutch computer scientist Edsger W. Dijkstra (he used the names `P()` and `V()` instead of *acquire()* and *release()*).

A semaphore manages an internal counter which is decremented by each *acquire()* call and incremented by each *release()* call. The counter can never go below zero; when *acquire()* finds that it is zero, it blocks, waiting until some other thread calls *release()*.

Semaphores also support the *context management protocol*.

class threading.Semaphore(*value=1*)

This class implements semaphore objects. A semaphore manages an atomic counter representing the number of *release()* calls minus the number of *acquire()* calls, plus an initial value. The *acquire()* method blocks if necessary until it can return without making the counter negative. If not given, *value* defaults to 1.

The optional argument gives the initial *value* for the internal counter; it defaults to `1`. If the *value* given is less than 0, *ValueError* is raised.

Changed in version 3.3: changed from a factory function to a class.

acquire(*blocking=True*, *timeout=None*)

Acquire a semaphore.

When invoked without arguments:

- If the internal counter is larger than zero on entry, decrement it by one and return true immediately.
- If the internal counter is zero on entry, block until awoken by a call to *release()*. Once awoken (and the counter is greater than 0), decrement the counter by 1 and return true. Exactly one thread will be awoken by each call to *release()*. The order in which threads are awoken should not be relied on.

When invoked with *blocking* set to false, do not block. If a call without an argument would block, return false immediately; otherwise, do the same thing as when called without arguments, and return true.

When invoked with a *timeout* other than `None`, it will block for at most *timeout* seconds. If acquire does not complete successfully in that interval, return false. Return true otherwise.

Changed in version 3.2: The *timeout* parameter is new.

release()

Release a semaphore, incrementing the internal counter by one. When it was zero on entry and another thread is waiting for it to become larger than zero again, wake up that thread.

class threading.BoundedSemaphore(*value=1*)

Class implementing bounded semaphore objects. A bounded semaphore checks to make sure its current value doesn't exceed its initial value. If it does, *ValueError* is raised. In most situations semaphores are used to guard resources with limited capacity. If the semaphore is released too many times it's a sign of a bug. If not given, *value* defaults to 1.

Changed in version 3.3: changed from a factory function to a class.

`Semaphore` Example

Semaphores are often used to guard resources with limited capacity, for example, a database server. In any situation where the size of the resource is fixed, you should use a bounded semaphore. Before spawning any worker threads, your main thread would initialize the semaphore:

```
maxconnections = 5
# ...
pool_sema = BoundedSemaphore(value=maxconnections)
```

Once spawned, worker threads call the semaphore's acquire and release methods when they need to connect to the server:

```
with pool_sema:
    conn = connectdb()
    try:
        # ... use connection ...
    finally:
        conn.close()
```

The use of a bounded semaphore reduces the chance that a programming error which causes the semaphore to be released more than it's acquired will go undetected.

17.1.7 Event Objects

This is one of the simplest mechanisms for communication between threads: one thread signals an event and other threads wait for it.

An event object manages an internal flag that can be set to true with the *set()* method and reset to false with the *clear()* method. The *wait()* method blocks until the flag is true.

class threading.Event

Class implementing event objects. An event manages a flag that can be set to true with the *set()* method and reset to false with the *clear()* method. The *wait()* method blocks until the flag is true. The flag is initially false.

Changed in version 3.3: changed from a factory function to a class.

is_set()

Return true if and only if the internal flag is true.

set()

Set the internal flag to true. All threads waiting for it to become true are awakened. Threads that call *wait()* once the flag is true will not block at all.

clear()

Reset the internal flag to false. Subsequently, threads calling *wait()* will block until *set()* is called to set the internal flag to true again.

wait(*timeout=None*)

Block until the internal flag is true. If the internal flag is true on entry, return immediately. Otherwise, block until another thread calls *set()* to set the flag to true, or until the optional timeout occurs.

When the timeout argument is present and not `None`, it should be a floating point number specifying a timeout for the operation in seconds (or fractions thereof).

This method returns true if and only if the internal flag has been set to true, either before the wait call or after the wait starts, so it will always return `True` except if a timeout is given and the operation times out.

Changed in version 3.1: Previously, the method always returned `None`.

17.1.8 Timer Objects

This class represents an action that should be run only after a certain amount of time has passed — a timer. *Timer* is a subclass of *Thread* and as such also functions as an example of creating custom threads.

Timers are started, as with threads, by calling their `start()` method. The timer can be stopped (before its action has begun) by calling the *cancel()* method. The interval the timer will wait before executing its action may not be exactly the same as the interval specified by the user.

For example:

```
def hello():
    print("hello, world")

t = Timer(30.0, hello)
t.start()  # after 30 seconds, "hello, world" will be printed
```

class threading.Timer(*interval*, *function*, *args=None*, *kwargs=None*)

Create a timer that will run *function* with arguments *args* and keyword arguments *kwargs*, after *interval* seconds have passed. If *args* is `None` (the default) then an empty list will be used. If *kwargs* is `None` (the default) then an empty dict will be used.

Changed in version 3.3: changed from a factory function to a class.

cancel()

Stop the timer, and cancel the execution of the timer's action. This will only work if the timer is still in its waiting stage.

17.1.9 Barrier Objects

New in version 3.2.

This class provides a simple synchronization primitive for use by a fixed number of threads that need to wait for each other. Each of the threads tries to pass the barrier by calling the *wait()* method and will block until all of the threads have made their *wait()* calls. At this point, the threads are released simultaneously.

The barrier can be reused any number of times for the same number of threads.

As an example, here is a simple way to synchronize a client and server thread:

```
b = Barrier(2, timeout=5)

def server():
    start_server()
    b.wait()
    while True:
        connection = accept_connection()
        process_server_connection(connection)

def client():
    b.wait()
    while True:
        connection = make_connection()
        process_client_connection(connection)
```

class threading.Barrier(*parties*, *action=None*, *timeout=None*)

Create a barrier object for *parties* number of threads. An *action*, when provided, is a callable to be called by one of the threads when they are released. *timeout* is the default timeout value if none is specified for the *wait()* method.

wait(*timeout=None*)
Pass the barrier. When all the threads party to the barrier have called this function, they are all released simultaneously. If a *timeout* is provided, it is used in preference to any that was supplied to the class constructor.

The return value is an integer in the range 0 to *parties* – 1, different for each thread. This can be used to select a thread to do some special housekeeping, e.g.:

```
i = barrier.wait()
if i == 0:
    # Only one thread needs to print this
    print("passed the barrier")
```

If an *action* was provided to the constructor, one of the threads will have called it prior to being released. Should this call raise an error, the barrier is put into the broken state.

If the call times out, the barrier is put into the broken state.

This method may raise a *BrokenBarrierError* exception if the barrier is broken or reset while a thread is waiting.

reset()
Return the barrier to the default, empty state. Any threads waiting on it will receive the *BrokenBarrierError* exception.

Note that using this function may can require some external synchronization if there are other threads whose state is unknown. If a barrier is broken it may be better to just leave it and create a new one.

abort()
Put the barrier into a broken state. This causes any active or future calls to *wait()* to fail with the *BrokenBarrierError*. Use this for example if one of the needs to abort, to avoid deadlocking the application.

It may be preferable to simply create the barrier with a sensible *timeout* value to automatically guard against one of the threads going awry.

parties
The number of threads required to pass the barrier.

n_waiting
The number of threads currently waiting in the barrier.

broken
A boolean that is `True` if the barrier is in the broken state.

exception threading.BrokenBarrierError
This exception, a subclass of *RuntimeError*, is raised when the *Barrier* object is reset or broken.

17.1.10 Using locks, conditions, and semaphores in the `with` statement

All of the objects provided by this module that have `acquire()` and `release()` methods can be used as context managers for a `with` statement. The `acquire()` method will be called when the block is entered, and `release()` will be called when the block is exited. Hence, the following snippet:

```
with some_lock:
    # do something...
```

is equivalent to:

```
some_lock.acquire()
try:
    # do something...
finally:
    some_lock.release()
```

Currently, *Lock*, *RLock*, *Condition*, *Semaphore*, and *BoundedSemaphore* objects may be used as `with` statement context managers.

17.2 `multiprocessing` — Process-based parallelism

Source code: Lib/multiprocessing/

17.2.1 Introduction

multiprocessing is a package that supports spawning processes using an API similar to the *threading* module. The *multiprocessing* package offers both local and remote concurrency, effectively side-stepping the *Global Interpreter Lock* by using subprocesses instead of threads. Due to this, the *multiprocessing* module allows the programmer to fully leverage multiple processors on a given machine. It runs on both Unix and Windows.

The *multiprocessing* module also introduces APIs which do not have analogs in the *threading* module. A prime example of this is the *Pool* object which offers a convenient means of parallelizing the execution of a function across multiple input values, distributing the input data across processes (data parallelism). The following example demonstrates the common practice of defining such functions in a module so that child processes can successfully import that module. This basic example of data parallelism using *Pool*,

```
from multiprocessing import Pool

def f(x):
    return x*x

if __name__ == '__main__':
    with Pool(5) as p:
        print(p.map(f, [1, 2, 3]))
```

will print to standard output

```
[1, 4, 9]
```

The `Process` class

In *multiprocessing*, processes are spawned by creating a *Process* object and then calling its *start()* method. *Process* follows the API of *threading.Thread*. A trivial example of a multiprocess program is

```
from multiprocessing import Process

def f(name):
    print('hello', name)
```

(continues on next page)

(continued from previous page)

```
if __name__ == '__main__':
    p = Process(target=f, args=('bob',))
    p.start()
    p.join()
```

To show the individual process IDs involved, here is an expanded example:

```
from multiprocessing import Process
import os

def info(title):
    print(title)
    print('module name:', __name__)
    print('parent process:', os.getppid())
    print('process id:', os.getpid())

def f(name):
    info('function f')
    print('hello', name)

if __name__ == '__main__':
    info('main line')
    p = Process(target=f, args=('bob',))
    p.start()
    p.join()
```

For an explanation of why the `if __name__ == '__main__'` part is necessary, see *Programming guidelines*.

Contexts and start methods

Depending on the platform, *multiprocessing* supports three ways to start a process. These *start methods* are

spawn The parent process starts a fresh python interpreter process. The child process will only inherit those resources necessary to run the process objects *run()* method. In particular, unnecessary file descriptors and handles from the parent process will not be inherited. Starting a process using this method is rather slow compared to using *fork* or *forkserver*.

Available on Unix and Windows. The default on Windows.

fork The parent process uses *os.fork()* to fork the Python interpreter. The child process, when it begins, is effectively identical to the parent process. All resources of the parent are inherited by the child process. Note that safely forking a multithreaded process is problematic.

Available on Unix only. The default on Unix.

forkserver When the program starts and selects the *forkserver* start method, a server process is started. From then on, whenever a new process is needed, the parent process connects to the server and requests that it fork a new process. The fork server process is single threaded so it is safe for it to use *os.fork()*. No unnecessary resources are inherited.

Available on Unix platforms which support passing file descriptors over Unix pipes.

Changed in version 3.4: *spawn* added on all unix platforms, and *forkserver* added for some unix platforms. Child processes no longer inherit all of the parents inheritable handles on Windows.

On Unix using the *spawn* or *forkserver* start methods will also start a *semaphore tracker* process which tracks the unlinked named semaphores created by processes of the program. When all processes have exited the

semaphore tracker unlinks any remaining semaphores. Usually there should be none, but if a process was killed by a signal there may be some "leaked" semaphores. (Unlinking the named semaphores is a serious matter since the system allows only a limited number, and they will not be automatically unlinked until the next reboot.)

To select a start method you use the *set_start_method()* in the `if __name__ == '__main__'` clause of the main module. For example:

```
import multiprocessing as mp

def foo(q):
    q.put('hello')

if __name__ == '__main__':
    mp.set_start_method('spawn')
    q = mp.Queue()
    p = mp.Process(target=foo, args=(q,))
    p.start()
    print(q.get())
    p.join()
```

set_start_method() should not be used more than once in the program.

Alternatively, you can use *get_context()* to obtain a context object. Context objects have the same API as the multiprocessing module, and allow one to use multiple start methods in the same program.

```
import multiprocessing as mp

def foo(q):
    q.put('hello')

if __name__ == '__main__':
    ctx = mp.get_context('spawn')
    q = ctx.Queue()
    p = ctx.Process(target=foo, args=(q,))
    p.start()
    print(q.get())
    p.join()
```

Note that objects related to one context may not be compatible with processes for a different context. In particular, locks created using the *fork* context cannot be passed to processes started using the *spawn* or *forkserver* start methods.

A library which wants to use a particular start method should probably use *get_context()* to avoid interfering with the choice of the library user.

Exchanging objects between processes

multiprocessing supports two types of communication channel between processes:

Queues

The *Queue* class is a near clone of *queue.Queue*. For example:

```
from multiprocessing import Process, Queue

def f(q):
    q.put([42, None, 'hello'])
```

(continues on next page)

(continued from previous page)

```
if __name__ == '__main__':
    q = Queue()
    p = Process(target=f, args=(q,))
    p.start()
    print(q.get())    # prints "[42, None, 'hello']"
    p.join()
```

Queues are thread and process safe.

Pipes

The *Pipe()* function returns a pair of connection objects connected by a pipe which by default is duplex (two-way). For example:

```
from multiprocessing import Process, Pipe

def f(conn):
    conn.send([42, None, 'hello'])
    conn.close()

if __name__ == '__main__':
    parent_conn, child_conn = Pipe()
    p = Process(target=f, args=(child_conn,))
    p.start()
    print(parent_conn.recv())   # prints "[42, None, 'hello']"
    p.join()
```

The two connection objects returned by *Pipe()* represent the two ends of the pipe. Each connection object has `send()` and `recv()` methods (among others). Note that data in a pipe may become corrupted if two processes (or threads) try to read from or write to the *same* end of the pipe at the same time. Of course there is no risk of corruption from processes using different ends of the pipe at the same time.

Synchronization between processes

multiprocessing contains equivalents of all the synchronization primitives from *threading*. For instance one can use a lock to ensure that only one process prints to standard output at a time:

```
from multiprocessing import Process, Lock

def f(l, i):
    l.acquire()
    try:
        print('hello world', i)
    finally:
        l.release()

if __name__ == '__main__':
    lock = Lock()

    for num in range(10):
        Process(target=f, args=(lock, num)).start()
```

Without using the lock output from the different processes is liable to get all mixed up.

Sharing state between processes

As mentioned above, when doing concurrent programming it is usually best to avoid using shared state as far as possible. This is particularly true when using multiple processes.

However, if you really do need to use some shared data then *multiprocessing* provides a couple of ways of doing so.

Shared memory

Data can be stored in a shared memory map using *Value* or *Array*. For example, the following code

```
from multiprocessing import Process, Value, Array

def f(n, a):
    n.value = 3.1415927
    for i in range(len(a)):
        a[i] = -a[i]

if __name__ == '__main__':
    num = Value('d', 0.0)
    arr = Array('i', range(10))

    p = Process(target=f, args=(num, arr))
    p.start()
    p.join()

    print(num.value)
    print(arr[:])
```

will print

```
3.1415927
[0, -1, -2, -3, -4, -5, -6, -7, -8, -9]
```

The `'d'` and `'i'` arguments used when creating `num` and `arr` are typecodes of the kind used by the *array* module: `'d'` indicates a double precision float and `'i'` indicates a signed integer. These shared objects will be process and thread-safe.

For more flexibility in using shared memory one can use the *multiprocessing.sharedctypes* module which supports the creation of arbitrary ctypes objects allocated from shared memory.

Server process

A manager object returned by `Manager()` controls a server process which holds Python objects and allows other processes to manipulate them using proxies.

A manager returned by `Manager()` will support types *list*, *dict*, *Namespace*, *Lock*, *RLock*, *Semaphore*, *BoundedSemaphore*, *Condition*, *Event*, *Barrier*, *Queue*, *Value* and *Array*. For example,

```
from multiprocessing import Process, Manager

def f(d, l):
    d[1] = '1'
    d['2'] = 2
    d[0.25] = None
    l.reverse()
```

(continues on next page)

(continued from previous page)

```
if __name__ == '__main__':
    with Manager() as manager:
        d = manager.dict()
        l = manager.list(range(10))

        p = Process(target=f, args=(d, l))
        p.start()
        p.join()

        print(d)
        print(l)
```

will print

```
{0.25: None, 1: '1', '2': 2}
[9, 8, 7, 6, 5, 4, 3, 2, 1, 0]
```

Server process managers are more flexible than using shared memory objects because they can be made to support arbitrary object types. Also, a single manager can be shared by processes on different computers over a network. They are, however, slower than using shared memory.

Using a pool of workers

The *Pool* class represents a pool of worker processes. It has methods which allows tasks to be offloaded to the worker processes in a few different ways.

For example:

```
from multiprocessing import Pool, TimeoutError
import time
import os

def f(x):
    return x*x

if __name__ == '__main__':
    # start 4 worker processes
    with Pool(processes=4) as pool:

        # print "[0, 1, 4,..., 81]"
        print(pool.map(f, range(10)))

        # print same numbers in arbitrary order
        for i in pool.imap_unordered(f, range(10)):
            print(i)

        # evaluate "f(20)" asynchronously
        res = pool.apply_async(f, (20,))      # runs in *only* one process
        print(res.get(timeout=1))             # prints "400"

        # evaluate "os.getpid()" asynchronously
        res = pool.apply_async(os.getpid, ()) # runs in *only* one process
        print(res.get(timeout=1))             # prints the PID of that process

        # launching multiple evaluations asynchronously *may* use more processes
        multiple_results = [pool.apply_async(os.getpid, ()) for i in range(4)]
```

(continues on next page)

(continued from previous page)

```
        print([res.get(timeout=1) for res in multiple_results])

        # make a single worker sleep for 10 secs
        res = pool.apply_async(time.sleep, (10,))
        try:
            print(res.get(timeout=1))
        except TimeoutError:
            print("We lacked patience and got a multiprocessing.TimeoutError")

        print("For the moment, the pool remains available for more work")

    # exiting the 'with'-block has stopped the pool
    print("Now the pool is closed and no longer available")
```

Note that the methods of a pool should only ever be used by the process which created it.

Note: Functionality within this package requires that the `__main__` module be importable by the children. This is covered in *Programming guidelines* however it is worth pointing out here. This means that some examples, such as the *multiprocessing.pool.Pool* examples will not work in the interactive interpreter. For example:

```
>>> from multiprocessing import Pool
>>> p = Pool(5)
>>> def f(x):
...     return x*x
...
>>> p.map(f, [1,2,3])
Process PoolWorker-1:
Process PoolWorker-2:
Process PoolWorker-3:
Traceback (most recent call last):
AttributeError: 'module' object has no attribute 'f'
AttributeError: 'module' object has no attribute 'f'
AttributeError: 'module' object has no attribute 'f'
```

(If you try this it will actually output three full tracebacks interleaved in a semi-random fashion, and then you may have to stop the master process somehow.)

17.2.2 Reference

The *multiprocessing* package mostly replicates the API of the *threading* module.

Process and exceptions

class multiprocessing.Process(*group=None*, *target=None*, *name=None*, *args=()*, *kwargs={}*, ***, *daemon=None*)

Process objects represent activity that is run in a separate process. The *Process* class has equivalents of all the methods of *threading.Thread*.

The constructor should always be called with keyword arguments. *group* should always be `None`; it exists solely for compatibility with *threading.Thread*. *target* is the callable object to be invoked by the *run()* method. It defaults to `None`, meaning nothing is called. *name* is the process name (see *name* for more details). *args* is the argument tuple for the target invocation. *kwargs* is a dictionary

of keyword arguments for the target invocation. If provided, the keyword-only *daemon* argument sets the process *daemon* flag to `True` or `False`. If `None` (the default), this flag will be inherited from the creating process.

By default, no arguments are passed to *target*.

If a subclass overrides the constructor, it must make sure it invokes the base class constructor (`Process.__init__()`) before doing anything else to the process.

Changed in version 3.3: Added the *daemon* argument.

run()
Method representing the process's activity.

You may override this method in a subclass. The standard *run()* method invokes the callable object passed to the object's constructor as the target argument, if any, with sequential and keyword arguments taken from the *args* and *kwargs* arguments, respectively.

start()
Start the process's activity.

This must be called at most once per process object. It arranges for the object's *run()* method to be invoked in a separate process.

join([*timeout*]**)**
If the optional argument *timeout* is `None` (the default), the method blocks until the process whose *join()* method is called terminates. If *timeout* is a positive number, it blocks at most *timeout* seconds. Note that the method returns `None` if its process terminates or if the method times out. Check the process's *exitcode* to determine if it terminated.

A process can be joined many times.

A process cannot join itself because this would cause a deadlock. It is an error to attempt to join a process before it has been started.

name
The process's name. The name is a string used for identification purposes only. It has no semantics. Multiple processes may be given the same name.

The initial name is set by the constructor. If no explicit name is provided to the constructor, a name of the form 'Process-N_1:N_2:...:N_k' is constructed, where each N_k is the N-th child of its parent.

is_alive()
Return whether the process is alive.

Roughly, a process object is alive from the moment the *start()* method returns until the child process terminates.

daemon
The process's daemon flag, a Boolean value. This must be set before *start()* is called.

The initial value is inherited from the creating process.

When a process exits, it attempts to terminate all of its daemonic child processes.

Note that a daemonic process is not allowed to create child processes. Otherwise a daemonic process would leave its children orphaned if it gets terminated when its parent process exits. Additionally, these are **not** Unix daemons or services, they are normal processes that will be terminated (and not joined) if non-daemonic processes have exited.

In addition to the *threading.Thread* API, *Process* objects also support the following attributes and methods:

pid
Return the process ID. Before the process is spawned, this will be `None`.

exitcode
The child's exit code. This will be `None` if the process has not yet terminated. A negative value *-N* indicates that the child was terminated by signal *N*.

authkey
The process's authentication key (a byte string).

When *multiprocessing* is initialized the main process is assigned a random string using *os.urandom()*.

When a *Process* object is created, it will inherit the authentication key of its parent process, although this may be changed by setting *authkey* to another byte string.

See *Authentication keys*.

sentinel
A numeric handle of a system object which will become "ready" when the process ends.

You can use this value if you want to wait on several events at once using *multiprocessing.connection.wait()*. Otherwise calling *join()* is simpler.

On Windows, this is an OS handle usable with the `WaitForSingleObject` and `WaitForMultipleObjects` family of API calls. On Unix, this is a file descriptor usable with primitives from the *select* module.

New in version 3.3.

terminate()
Terminate the process. On Unix this is done using the `SIGTERM` signal; on Windows `TerminateProcess()` is used. Note that exit handlers and finally clauses, etc., will not be executed.

Note that descendant processes of the process will *not* be terminated – they will simply become orphaned.

> **Warning:** If this method is used when the associated process is using a pipe or queue then the pipe or queue is liable to become corrupted and may become unusable by other process. Similarly, if the process has acquired a lock or semaphore etc. then terminating it is liable to cause other processes to deadlock.

kill()
Same as *terminate()* but using the `SIGKILL` signal on Unix.

New in version 3.7.

close()
Close the *Process* object, releasing all resources associated with it. *ValueError* is raised if the underlying process is still running. Once *close()* returns successfully, most other methods and attributes of the *Process* object will raise *ValueError*.

New in version 3.7.

Note that the *start()*, *join()*, *is_alive()*, *terminate()* and *exitcode* methods should only be called by the process that created the process object.

Example usage of some of the methods of *Process*:

```
>>> import multiprocessing, time, signal
>>> p = multiprocessing.Process(target=time.sleep, args=(1000,))
>>> print(p, p.is_alive())
<Process(Process-1, initial)> False
>>> p.start()
>>> print(p, p.is_alive())
<Process(Process-1, started)> True
>>> p.terminate()
>>> time.sleep(0.1)
>>> print(p, p.is_alive())
<Process(Process-1, stopped[SIGTERM])> False
>>> p.exitcode == -signal.SIGTERM
True
```

exception multiprocessing.ProcessError
The base class of all *multiprocessing* exceptions.

exception multiprocessing.BufferTooShort
Exception raised by `Connection.recv_bytes_into()` when the supplied buffer object is too small for the message read.

If `e` is an instance of *BufferTooShort* then `e.args[0]` will give the message as a byte string.

exception multiprocessing.AuthenticationError
Raised when there is an authentication error.

exception multiprocessing.TimeoutError
Raised by methods with a timeout when the timeout expires.

Pipes and Queues

When using multiple processes, one generally uses message passing for communication between processes and avoids having to use any synchronization primitives like locks.

For passing messages one can use *Pipe()* (for a connection between two processes) or a queue (which allows multiple producers and consumers).

The *Queue*, *SimpleQueue* and *JoinableQueue* types are multi-producer, multi-consumer FIFO queues modelled on the *queue.Queue* class in the standard library. They differ in that *Queue* lacks the *task_done()* and *join()* methods introduced into Python 2.5's *queue.Queue* class.

If you use *JoinableQueue* then you **must** call *JoinableQueue.task_done()* for each task removed from the queue or else the semaphore used to count the number of unfinished tasks may eventually overflow, raising an exception.

Note that one can also create a shared queue by using a manager object – see *Managers*.

Note: *multiprocessing* uses the usual *queue.Empty* and *queue.Full* exceptions to signal a timeout. They are not available in the *multiprocessing* namespace so you need to import them from *queue*.

Note: When an object is put on a queue, the object is pickled and a background thread later flushes the pickled data to an underlying pipe. This has some consequences which are a little surprising, but should not cause any practical difficulties – if they really bother you then you can instead use a queue created with a *manager*.

1. After putting an object on an empty queue there may be an infinitesimal delay before the queue's *empty()* method returns *False* and *get_nowait()* can return without raising *queue.Empty*.

2. If multiple processes are enqueuing objects, it is possible for the objects to be received at the other end out-of-order. However, objects enqueued by the same process will always be in the expected order with respect to each other.

Warning: If a process is killed using *Process.terminate()* or *os.kill()* while it is trying to use a *Queue*, then the data in the queue is likely to become corrupted. This may cause any other process to get an exception when it tries to use the queue later on.

Warning: As mentioned above, if a child process has put items on a queue (and it has not used *JoinableQueue.cancel_join_thread*), then that process will not terminate until all buffered items have been flushed to the pipe.

This means that if you try joining that process you may get a deadlock unless you are sure that all items which have been put on the queue have been consumed. Similarly, if the child process is non-daemonic then the parent process may hang on exit when it tries to join all its non-daemonic children.

Note that a queue created using a manager does not have this issue. See *Programming guidelines*.

For an example of the usage of queues for interprocess communication see *Examples*.

`multiprocessing.Pipe`([*duplex*])
: Returns a pair `(conn1, conn2)` of *Connection* objects representing the ends of a pipe.

  If *duplex* is `True` (the default) then the pipe is bidirectional. If *duplex* is `False` then the pipe is unidirectional: `conn1` can only be used for receiving messages and `conn2` can only be used for sending messages.

`class multiprocessing.Queue`([*maxsize*])
: Returns a process shared queue implemented using a pipe and a few locks/semaphores. When a process first puts an item on the queue a feeder thread is started which transfers objects from a buffer into the pipe.

  The usual *queue.Empty* and *queue.Full* exceptions from the standard library's *queue* module are raised to signal timeouts.

  Queue implements all the methods of *queue.Queue* except for *task_done()* and *join()*.

  `qsize()`
  : Return the approximate size of the queue. Because of multithreading/multiprocessing semantics, this number is not reliable.

    Note that this may raise *NotImplementedError* on Unix platforms like Mac OS X where `sem_getvalue()` is not implemented.

  `empty()`
  : Return `True` if the queue is empty, `False` otherwise. Because of multithreading/multiprocessing semantics, this is not reliable.

  `full()`
  : Return `True` if the queue is full, `False` otherwise. Because of multithreading/multiprocessing semantics, this is not reliable.

  `put`(*obj*[, *block*[, *timeout*]])
  : Put obj into the queue. If the optional argument *block* is `True` (the default) and *timeout* is `None` (the default), block if necessary until a free slot is available. If *timeout* is a positive number, it blocks at most *timeout* seconds and raises the *queue.Full* exception if no free slot was available

within that time. Otherwise (*block* is `False`), put an item on the queue if a free slot is immediately available, else raise the *queue.Full* exception (*timeout* is ignored in that case).

`put_nowait(`*obj*`)`
Equivalent to `put(obj, False)`.

`get(`[*block*[, *timeout*]]`)`
Remove and return an item from the queue. If optional args *block* is `True` (the default) and *timeout* is `None` (the default), block if necessary until an item is available. If *timeout* is a positive number, it blocks at most *timeout* seconds and raises the *queue.Empty* exception if no item was available within that time. Otherwise (block is `False`), return an item if one is immediately available, else raise the *queue.Empty* exception (*timeout* is ignored in that case).

`get_nowait()`
Equivalent to `get(False)`.

multiprocessing.Queue has a few additional methods not found in *queue.Queue*. These methods are usually unnecessary for most code:

`close()`
Indicate that no more data will be put on this queue by the current process. The background thread will quit once it has flushed all buffered data to the pipe. This is called automatically when the queue is garbage collected.

`join_thread()`
Join the background thread. This can only be used after *close()* has been called. It blocks until the background thread exits, ensuring that all data in the buffer has been flushed to the pipe.

By default if a process is not the creator of the queue then on exit it will attempt to join the queue's background thread. The process can call *cancel_join_thread()* to make *join_thread()* do nothing.

`cancel_join_thread()`
Prevent *join_thread()* from blocking. In particular, this prevents the background thread from being joined automatically when the process exits – see *join_thread()*.

A better name for this method might be `allow_exit_without_flush()`. It is likely to cause enqueued data to lost, and you almost certainly will not need to use it. It is really only there if you need the current process to exit immediately without waiting to flush enqueued data to the underlying pipe, and you don't care about lost data.

Note: This class's functionality requires a functioning shared semaphore implementation on the host operating system. Without one, the functionality in this class will be disabled, and attempts to instantiate a *Queue* will result in an *ImportError*. See bpo-3770 for additional information. The same holds true for any of the specialized queue types listed below.

`class multiprocessing.SimpleQueue`
It is a simplified *Queue* type, very close to a locked *Pipe*.

`empty()`
Return `True` if the queue is empty, `False` otherwise.

`get()`
Remove and return an item from the queue.

`put(`*item*`)`
Put *item* into the queue.

`class multiprocessing.JoinableQueue(`[*maxsize*]`)`
JoinableQueue, a *Queue* subclass, is a queue which additionally has *task_done()* and *join()* methods.

task_done()
Indicate that a formerly enqueued task is complete. Used by queue consumers. For each *get()* used to fetch a task, a subsequent call to *task_done()* tells the queue that the processing on the task is complete.

If a *join()* is currently blocking, it will resume when all items have been processed (meaning that a *task_done()* call was received for every item that had been *put()* into the queue).

Raises a *ValueError* if called more times than there were items placed in the queue.

join()
Block until all items in the queue have been gotten and processed.

The count of unfinished tasks goes up whenever an item is added to the queue. The count goes down whenever a consumer calls *task_done()* to indicate that the item was retrieved and all work on it is complete. When the count of unfinished tasks drops to zero, *join()* unblocks.

Miscellaneous

multiprocessing.active_children()
Return list of all live children of the current process.

Calling this has the side effect of "joining" any processes which have already finished.

multiprocessing.cpu_count()
Return the number of CPUs in the system.

This number is not equivalent to the number of CPUs the current process can use. The number of usable CPUs can be obtained with `len(os.sched_getaffinity(0))`

May raise *NotImplementedError*.

See also:

os.cpu_count()

multiprocessing.current_process()
Return the *Process* object corresponding to the current process.

An analogue of *threading.current_thread()*.

multiprocessing.freeze_support()
Add support for when a program which uses *multiprocessing* has been frozen to produce a Windows executable. (Has been tested with **py2exe**, **PyInstaller** and **cx_Freeze**.)

One needs to call this function straight after the `if __name__ == '__main__'` line of the main module. For example:

```
from multiprocessing import Process, freeze_support

def f():
    print('hello world!')

if __name__ == '__main__':
    freeze_support()
    Process(target=f).start()
```

If the `freeze_support()` line is omitted then trying to run the frozen executable will raise *RuntimeError*.

Calling `freeze_support()` has no effect when invoked on any operating system other than Windows. In addition, if the module is being run normally by the Python interpreter on Windows (the program has not been frozen), then `freeze_support()` has no effect.

`multiprocessing.get_all_start_methods()`
Returns a list of the supported start methods, the first of which is the default. The possible start methods are `'fork'`, `'spawn'` and `'forkserver'`. On Windows only `'spawn'` is available. On Unix `'fork'` and `'spawn'` are always supported, with `'fork'` being the default.

New in version 3.4.

`multiprocessing.get_context(`*method=None*`)`
Return a context object which has the same attributes as the *multiprocessing* module.

If *method* is `None` then the default context is returned. Otherwise *method* should be `'fork'`, `'spawn'`, `'forkserver'`. *ValueError* is raised if the specified start method is not available.

New in version 3.4.

`multiprocessing.get_start_method(`*allow_none=False*`)`
Return the name of start method used for starting processes.

If the start method has not been fixed and *allow_none* is false, then the start method is fixed to the default and the name is returned. If the start method has not been fixed and *allow_none* is true then `None` is returned.

The return value can be `'fork'`, `'spawn'`, `'forkserver'` or `None`. `'fork'` is the default on Unix, while `'spawn'` is the default on Windows.

New in version 3.4.

`multiprocessing.set_executable()`
Sets the path of the Python interpreter to use when starting a child process. (By default *sys.executable* is used). Embedders will probably need to do some thing like

```
set_executable(os.path.join(sys.exec_prefix, 'pythonw.exe'))
```

before they can create child processes.

Changed in version 3.4: Now supported on Unix when the `'spawn'` start method is used.

`multiprocessing.set_start_method(`*method*`)`
Set the method which should be used to start child processes. *method* can be `'fork'`, `'spawn'` or `'forkserver'`.

Note that this should be called at most once, and it should be protected inside the `if __name__ == '__main__'` clause of the main module.

New in version 3.4.

Note: *multiprocessing* contains no analogues of *threading.active_count()*, *threading.enumerate()*, *threading.settrace()*, *threading.setprofile()*, *threading.Timer*, or *threading.local*.

Connection Objects

Connection objects allow the sending and receiving of picklable objects or strings. They can be thought of as message oriented connected sockets.

Connection objects are usually created using *Pipe* – see also *Listeners and Clients*.

`class multiprocessing.connection.Connection`

send(*obj*)
Send an object to the other end of the connection which should be read using *recv()*.

The object must be picklable. Very large pickles (approximately 32 MiB+, though it depends on the OS) may raise a *ValueError* exception.

recv()
Return an object sent from the other end of the connection using *send()*. Blocks until there is something to receive. Raises *EOFError* if there is nothing left to receive and the other end was closed.

fileno()
Return the file descriptor or handle used by the connection.

close()
Close the connection.

This is called automatically when the connection is garbage collected.

poll([*timeout*])
Return whether there is any data available to be read.

If *timeout* is not specified then it will return immediately. If *timeout* is a number then this specifies the maximum time in seconds to block. If *timeout* is `None` then an infinite timeout is used.

Note that multiple connection objects may be polled at once by using *multiprocessing.connection.wait()*.

send_bytes(*buffer*[, *offset*[, *size*]])
Send byte data from a *bytes-like object* as a complete message.

If *offset* is given then data is read from that position in *buffer*. If *size* is given then that many bytes will be read from buffer. Very large buffers (approximately 32 MiB+, though it depends on the OS) may raise a *ValueError* exception

recv_bytes([*maxlength*])
Return a complete message of byte data sent from the other end of the connection as a string. Blocks until there is something to receive. Raises *EOFError* if there is nothing left to receive and the other end has closed.

If *maxlength* is specified and the message is longer than *maxlength* then *OSError* is raised and the connection will no longer be readable.

Changed in version 3.3: This function used to raise *IOError*, which is now an alias of *OSError*.

recv_bytes_into(*buffer*[, *offset*])
Read into *buffer* a complete message of byte data sent from the other end of the connection and return the number of bytes in the message. Blocks until there is something to receive. Raises *EOFError* if there is nothing left to receive and the other end was closed.

buffer must be a writable *bytes-like object*. If *offset* is given then the message will be written into the buffer from that position. Offset must be a non-negative integer less than the length of *buffer* (in bytes).

If the buffer is too short then a `BufferTooShort` exception is raised and the complete message is available as `e.args[0]` where `e` is the exception instance.

Changed in version 3.3: Connection objects themselves can now be transferred between processes using *Connection.send()* and *Connection.recv()*.

New in version 3.3: Connection objects now support the context management protocol – see *Context Manager Types*. *__enter__()* returns the connection object, and *__exit__()* calls *close()*.

For example:

```
>>> from multiprocessing import Pipe
>>> a, b = Pipe()
>>> a.send([1, 'hello', None])
>>> b.recv()
[1, 'hello', None]
>>> b.send_bytes(b'thank you')
>>> a.recv_bytes()
b'thank you'
>>> import array
>>> arr1 = array.array('i', range(5))
>>> arr2 = array.array('i', [0] * 10)
>>> a.send_bytes(arr1)
>>> count = b.recv_bytes_into(arr2)
>>> assert count == len(arr1) * arr1.itemsize
>>> arr2
array('i', [0, 1, 2, 3, 4, 0, 0, 0, 0, 0])
```

Warning: The *Connection.recv()* method automatically unpickles the data it receives, which can be a security risk unless you can trust the process which sent the message.

Therefore, unless the connection object was produced using `Pipe()` you should only use the *recv()* and *send()* methods after performing some sort of authentication. See *Authentication keys*.

Warning: If a process is killed while it is trying to read or write to a pipe then the data in the pipe is likely to become corrupted, because it may become impossible to be sure where the message boundaries lie.

Synchronization primitives

Generally synchronization primitives are not as necessary in a multiprocess program as they are in a multi-threaded program. See the documentation for *threading* module.

Note that one can also create synchronization primitives by using a manager object – see *Managers*.

class multiprocessing.**Barrier**(*parties*[, *action*[, *timeout*]])
A barrier object: a clone of *threading.Barrier*.

New in version 3.3.

class multiprocessing.**BoundedSemaphore**([*value*])
A bounded semaphore object: a close analog of *threading.BoundedSemaphore*.

A solitary difference from its close analog exists: its `acquire` method's first argument is named *block*, as is consistent with *Lock.acquire()*.

Note: On Mac OS X, this is indistinguishable from *Semaphore* because `sem_getvalue()` is not implemented on that platform.

class multiprocessing.**Condition**([*lock*])
A condition variable: an alias for *threading.Condition*.

If *lock* is specified then it should be a *Lock* or *RLock* object from *multiprocessing*.

Changed in version 3.3: The *wait_for()* method was added.

class multiprocessing.Event
A clone of *threading.Event*.

class multiprocessing.Lock
A non-recursive lock object: a close analog of *threading.Lock*. Once a process or thread has acquired a lock, subsequent attempts to acquire it from any process or thread will block until it is released; any process or thread may release it. The concepts and behaviors of *threading.Lock* as it applies to threads are replicated here in *multiprocessing.Lock* as it applies to either processes or threads, except as noted.

Note that *Lock* is actually a factory function which returns an instance of `multiprocessing.synchronize.Lock` initialized with a default context.

Lock supports the *context manager* protocol and thus may be used in `with` statements.

acquire(*block=True*, *timeout=None*)
Acquire a lock, blocking or non-blocking.

With the *block* argument set to `True` (the default), the method call will block until the lock is in an unlocked state, then set it to locked and return `True`. Note that the name of this first argument differs from that in *threading.Lock.acquire()*.

With the *block* argument set to `False`, the method call does not block. If the lock is currently in a locked state, return `False`; otherwise set the lock to a locked state and return `True`.

When invoked with a positive, floating-point value for *timeout*, block for at most the number of seconds specified by *timeout* as long as the lock can not be acquired. Invocations with a negative value for *timeout* are equivalent to a *timeout* of zero. Invocations with a *timeout* value of `None` (the default) set the timeout period to infinite. Note that the treatment of negative or `None` values for *timeout* differs from the implemented behavior in *threading.Lock.acquire()*. The *timeout* argument has no practical implications if the *block* argument is set to `False` and is thus ignored. Returns `True` if the lock has been acquired or `False` if the timeout period has elapsed.

release()
Release a lock. This can be called from any process or thread, not only the process or thread which originally acquired the lock.

Behavior is the same as in *threading.Lock.release()* except that when invoked on an unlocked lock, a *ValueError* is raised.

class multiprocessing.RLock
A recursive lock object: a close analog of *threading.RLock*. A recursive lock must be released by the process or thread that acquired it. Once a process or thread has acquired a recursive lock, the same process or thread may acquire it again without blocking; that process or thread must release it once for each time it has been acquired.

Note that *RLock* is actually a factory function which returns an instance of `multiprocessing.synchronize.RLock` initialized with a default context.

RLock supports the *context manager* protocol and thus may be used in `with` statements.

acquire(*block=True*, *timeout=None*)
Acquire a lock, blocking or non-blocking.

When invoked with the *block* argument set to `True`, block until the lock is in an unlocked state (not owned by any process or thread) unless the lock is already owned by the current process or thread. The current process or thread then takes ownership of the lock (if it does not already have ownership) and the recursion level inside the lock increments by one, resulting in a return value of `True`. Note that there are several differences in this first argument's behavior compared to the implementation of *threading.RLock.acquire()*, starting with the name of the argument itself.

When invoked with the *block* argument set to `False`, do not block. If the lock has already been acquired (and thus is owned) by another process or thread, the current process or thread does not take ownership and the recursion level within the lock is not changed, resulting in a return value of `False`. If the lock is in an unlocked state, the current process or thread takes ownership and the recursion level is incremented, resulting in a return value of `True`.

Use and behaviors of the *timeout* argument are the same as in *Lock.acquire()*. Note that some of these behaviors of *timeout* differ from the implemented behaviors in *threading.RLock.acquire()*.

`release()`
Release a lock, decrementing the recursion level. If after the decrement the recursion level is zero, reset the lock to unlocked (not owned by any process or thread) and if any other processes or threads are blocked waiting for the lock to become unlocked, allow exactly one of them to proceed. If after the decrement the recursion level is still nonzero, the lock remains locked and owned by the calling process or thread.

Only call this method when the calling process or thread owns the lock. An *AssertionError* is raised if this method is called by a process or thread other than the owner or if the lock is in an unlocked (unowned) state. Note that the type of exception raised in this situation differs from the implemented behavior in *threading.RLock.release()*.

`class multiprocessing.Semaphore(`[*value*]`)`
A semaphore object: a close analog of *threading.Semaphore*.

A solitary difference from its close analog exists: its `acquire` method's first argument is named *block*, as is consistent with *Lock.acquire()*.

Note: On Mac OS X, `sem_timedwait` is unsupported, so calling `acquire()` with a timeout will emulate that function's behavior using a sleeping loop.

Note: If the SIGINT signal generated by `Ctrl-C` arrives while the main thread is blocked by a call to `BoundedSemaphore.acquire()`, *Lock.acquire()*, *RLock.acquire()*, `Semaphore.acquire()`, `Condition.acquire()` or `Condition.wait()` then the call will be immediately interrupted and *KeyboardInterrupt* will be raised.

This differs from the behaviour of *threading* where SIGINT will be ignored while the equivalent blocking calls are in progress.

Note: Some of this package's functionality requires a functioning shared semaphore implementation on the host operating system. Without one, the `multiprocessing.synchronize` module will be disabled, and attempts to import it will result in an *ImportError*. See bpo-3770 for additional information.

Shared `ctypes` Objects

It is possible to create shared objects using shared memory which can be inherited by child processes.

`multiprocessing.Value(`*typecode_or_type*, **args*, *lock=True*`)`
Return a *ctypes* object allocated from shared memory. By default the return value is actually a synchronized wrapper for the object. The object itself can be accessed via the *value* attribute of a *Value*.

typecode_or_type determines the type of the returned object: it is either a ctypes type or a one character typecode of the kind used by the *array* module. **args* is passed on to the constructor for the type.

If *lock* is `True` (the default) then a new recursive lock object is created to synchronize access to the value. If *lock* is a *Lock* or *RLock* object then that will be used to synchronize access to the value. If *lock* is `False` then access to the returned object will not be automatically protected by a lock, so it will not necessarily be "process-safe".

Operations like `+=` which involve a read and write are not atomic. So if, for instance, you want to atomically increment a shared value it is insufficient to just do

```
counter.value += 1
```

Assuming the associated lock is recursive (which it is by default) you can instead do

```
with counter.get_lock():
    counter.value += 1
```

Note that *lock* is a keyword-only argument.

`multiprocessing.Array`(*typecode_or_type*, *size_or_initializer*, *, *lock=True*)
Return a ctypes array allocated from shared memory. By default the return value is actually a synchronized wrapper for the array.

typecode_or_type determines the type of the elements of the returned array: it is either a ctypes type or a one character typecode of the kind used by the *array* module. If *size_or_initializer* is an integer, then it determines the length of the array, and the array will be initially zeroed. Otherwise, *size_or_initializer* is a sequence which is used to initialize the array and whose length determines the length of the array.

If *lock* is `True` (the default) then a new lock object is created to synchronize access to the value. If *lock* is a *Lock* or *RLock* object then that will be used to synchronize access to the value. If *lock* is `False` then access to the returned object will not be automatically protected by a lock, so it will not necessarily be "process-safe".

Note that *lock* is a keyword only argument.

Note that an array of *ctypes.c_char* has *value* and *raw* attributes which allow one to use it to store and retrieve strings.

The `multiprocessing.sharedctypes` module

The *multiprocessing.sharedctypes* module provides functions for allocating *ctypes* objects from shared memory which can be inherited by child processes.

Note: Although it is possible to store a pointer in shared memory remember that this will refer to a location in the address space of a specific process. However, the pointer is quite likely to be invalid in the context of a second process and trying to dereference the pointer from the second process may cause a crash.

`multiprocessing.sharedctypes.RawArray`(*typecode_or_type*, *size_or_initializer*)
Return a ctypes array allocated from shared memory.

typecode_or_type determines the type of the elements of the returned array: it is either a ctypes type or a one character typecode of the kind used by the *array* module. If *size_or_initializer* is an integer then it determines the length of the array, and the array will be initially zeroed. Otherwise *size_or_initializer* is a sequence which is used to initialize the array and whose length determines the length of the array.

Note that setting and getting an element is potentially non-atomic – use *Array()* instead to make sure that access is automatically synchronized using a lock.

multiprocessing.sharedctypes.**RawValue**(*typecode_or_type*, **args*)
Return a ctypes object allocated from shared memory.

typecode_or_type determines the type of the returned object: it is either a ctypes type or a one character typecode of the kind used by the *array* module. **args* is passed on to the constructor for the type.

Note that setting and getting the value is potentially non-atomic – use *Value()* instead to make sure that access is automatically synchronized using a lock.

Note that an array of *ctypes.c_char* has `value` and `raw` attributes which allow one to use it to store and retrieve strings – see documentation for *ctypes*.

multiprocessing.sharedctypes.**Array**(*typecode_or_type*, *size_or_initializer*, *, *lock=True*)
The same as *RawArray()* except that depending on the value of *lock* a process-safe synchronization wrapper may be returned instead of a raw ctypes array.

If *lock* is `True` (the default) then a new lock object is created to synchronize access to the value. If *lock* is a *Lock* or *RLock* object then that will be used to synchronize access to the value. If *lock* is `False` then access to the returned object will not be automatically protected by a lock, so it will not necessarily be "process-safe".

Note that *lock* is a keyword-only argument.

multiprocessing.sharedctypes.**Value**(*typecode_or_type*, **args*, *lock=True*)
The same as *RawValue()* except that depending on the value of *lock* a process-safe synchronization wrapper may be returned instead of a raw ctypes object.

If *lock* is `True` (the default) then a new lock object is created to synchronize access to the value. If *lock* is a *Lock* or *RLock* object then that will be used to synchronize access to the value. If *lock* is `False` then access to the returned object will not be automatically protected by a lock, so it will not necessarily be "process-safe".

Note that *lock* is a keyword-only argument.

multiprocessing.sharedctypes.**copy**(*obj*)
Return a ctypes object allocated from shared memory which is a copy of the ctypes object *obj*.

multiprocessing.sharedctypes.**synchronized**(*obj*[, *lock*])
Return a process-safe wrapper object for a ctypes object which uses *lock* to synchronize access. If *lock* is `None` (the default) then a *multiprocessing.RLock* object is created automatically.

A synchronized wrapper will have two methods in addition to those of the object it wraps: `get_obj()` returns the wrapped object and `get_lock()` returns the lock object used for synchronization.

Note that accessing the ctypes object through the wrapper can be a lot slower than accessing the raw ctypes object.

Changed in version 3.5: Synchronized objects support the *context manager* protocol.

The table below compares the syntax for creating shared ctypes objects from shared memory with the normal ctypes syntax. (In the table `MyStruct` is some subclass of *ctypes.Structure*.)

ctypes	sharedctypes using type	sharedctypes using typecode
c_double(2.4)	RawValue(c_double, 2.4)	RawValue('d', 2.4)
MyStruct(4, 6)	RawValue(MyStruct, 4, 6)	
(c_short * 7)()	RawArray(c_short, 7)	RawArray('h', 7)
(c_int * 3)(9, 2, 8)	RawArray(c_int, (9, 2, 8))	RawArray('i', (9, 2, 8))

Below is an example where a number of ctypes objects are modified by a child process:

```
from multiprocessing import Process, Lock
from multiprocessing.sharedctypes import Value, Array
from ctypes import Structure, c_double

class Point(Structure):
    _fields_ = [('x', c_double), ('y', c_double)]

def modify(n, x, s, A):
    n.value **= 2
    x.value **= 2
    s.value = s.value.upper()
    for a in A:
        a.x **= 2
        a.y **= 2

if __name__ == '__main__':
    lock = Lock()

    n = Value('i', 7)
    x = Value(c_double, 1.0/3.0, lock=False)
    s = Array('c', b'hello world', lock=lock)
    A = Array(Point, [(1.875,-6.25), (-5.75,2.0), (2.375,9.5)], lock=lock)

    p = Process(target=modify, args=(n, x, s, A))
    p.start()
    p.join()

    print(n.value)
    print(x.value)
    print(s.value)
    print([(a.x, a.y) for a in A])
```

The results printed are

```
49
0.1111111111111111
HELLO WORLD
[(3.515625, 39.0625), (33.0625, 4.0), (5.640625, 90.25)]
```

Managers

Managers provide a way to create data which can be shared between different processes, including sharing over a network between processes running on different machines. A manager object controls a server process which manages *shared objects*. Other processes can access the shared objects by using proxies.

`multiprocessing.Manager()`
: Returns a started *SyncManager* object which can be used for sharing objects between processes. The returned manager object corresponds to a spawned child process and has methods which will create shared objects and return corresponding proxies.

Manager processes will be shutdown as soon as they are garbage collected or their parent process exits. The manager classes are defined in the *multiprocessing.managers* module:

class `multiprocessing.managers.BaseManager`(*[address[, authkey]]*)
: Create a BaseManager object.

  Once created one should call *start()* or `get_server().serve_forever()` to ensure that the manager object refers to a started manager process.

address is the address on which the manager process listens for new connections. If *address* is `None` then an arbitrary one is chosen.

authkey is the authentication key which will be used to check the validity of incoming connections to the server process. If *authkey* is `None` then `current_process().authkey` is used. Otherwise *authkey* is used and it must be a byte string.

`start`(*[initializer[, initargs]]*)
Start a subprocess to start the manager. If *initializer* is not `None` then the subprocess will call `initializer(*initargs)` when it starts.

`get_server`()
Returns a `Server` object which represents the actual server under the control of the Manager. The `Server` object supports the `serve_forever()` method:

```
>>> from multiprocessing.managers import BaseManager
>>> manager = BaseManager(address=('', 50000), authkey=b'abc')
>>> server = manager.get_server()
>>> server.serve_forever()
```

`Server` additionally has an *address* attribute.

`connect`()
Connect a local manager object to a remote manager process:

```
>>> from multiprocessing.managers import BaseManager
>>> m = BaseManager(address=('127.0.0.1', 5000), authkey=b'abc')
>>> m.connect()
```

`shutdown`()
Stop the process used by the manager. This is only available if *start()* has been used to start the server process.

This can be called multiple times.

`register`(*typeid[, callable[, proxytype[, exposed[, method_to_typeid[, create_method]]]]]*)
A classmethod which can be used for registering a type or callable with the manager class.

typeid is a "type identifier" which is used to identify a particular type of shared object. This must be a string.

callable is a callable used for creating objects for this type identifier. If a manager instance will be connected to the server using the *connect()* method, or if the *create_method* argument is `False` then this can be left as `None`.

proxytype is a subclass of *BaseProxy* which is used to create proxies for shared objects with this *typeid*. If `None` then a proxy class is created automatically.

exposed is used to specify a sequence of method names which proxies for this typeid should be allowed to access using *BaseProxy._callmethod()*. (If *exposed* is `None` then `proxytype._exposed_` is used instead if it exists.) In the case where no exposed list is specified, all "public methods" of the shared object will be accessible. (Here a "public method" means any attribute which has a `__call__()` method and whose name does not begin with `'_'`.)

method_to_typeid is a mapping used to specify the return type of those exposed methods which should return a proxy. It maps method names to typeid strings. (If *method_to_typeid* is `None` then `proxytype._method_to_typeid_` is used instead if it exists.) If a method's name is not a key of this mapping or if the mapping is `None` then the object returned by the method will be copied by value.

create_method determines whether a method should be created with name *typeid* which can be used to tell the server process to create a new shared object and return a proxy for it. By default it is `True`.

BaseManager instances also have one read-only property:

address
The address used by the manager.

Changed in version 3.3: Manager objects support the context management protocol – see *Context Manager Types*. *__enter__()* starts the server process (if it has not already started) and then returns the manager object. *__exit__()* calls *shutdown()*.

In previous versions *__enter__()* did not start the manager's server process if it was not already started.

class multiprocessing.managers.SyncManager
A subclass of *BaseManager* which can be used for the synchronization of processes. Objects of this type are returned by `multiprocessing.Manager()`.

Its methods create and return *Proxy Objects* for a number of commonly used data types to be synchronized across processes. This notably includes shared lists and dictionaries.

Barrier(*parties*[, *action*[, *timeout*]])
Create a shared *threading.Barrier* object and return a proxy for it.

New in version 3.3.

BoundedSemaphore([*value*])
Create a shared *threading.BoundedSemaphore* object and return a proxy for it.

Condition([*lock*])
Create a shared *threading.Condition* object and return a proxy for it.

If *lock* is supplied then it should be a proxy for a *threading.Lock* or *threading.RLock* object.

Changed in version 3.3: The *wait_for()* method was added.

Event()
Create a shared *threading.Event* object and return a proxy for it.

Lock()
Create a shared *threading.Lock* object and return a proxy for it.

Namespace()
Create a shared *Namespace* object and return a proxy for it.

Queue([*maxsize*])
Create a shared *queue.Queue* object and return a proxy for it.

RLock()
Create a shared *threading.RLock* object and return a proxy for it.

Semaphore([*value*])
Create a shared *threading.Semaphore* object and return a proxy for it.

Array(*typecode*, *sequence*)
Create an array and return a proxy for it.

Value(*typecode*, *value*)
Create an object with a writable `value` attribute and return a proxy for it.

dict()
dict(*mapping*)

dict(*sequence*)
Create a shared *dict* object and return a proxy for it.

list()
list(*sequence*)
Create a shared *list* object and return a proxy for it.

Changed in version 3.6: Shared objects are capable of being nested. For example, a shared container object such as a shared list can contain other shared objects which will all be managed and synchronized by the *SyncManager*.

class multiprocessing.managers.Namespace
A type that can register with *SyncManager*.

A namespace object has no public methods, but does have writable attributes. Its representation shows the values of its attributes.

However, when using a proxy for a namespace object, an attribute beginning with '_' will be an attribute of the proxy and not an attribute of the referent:

```
>>> manager = multiprocessing.Manager()
>>> Global = manager.Namespace()
>>> Global.x = 10
>>> Global.y = 'hello'
>>> Global._z = 12.3    # this is an attribute of the proxy
>>> print(Global)
Namespace(x=10, y='hello')
```

Customized managers

To create one's own manager, one creates a subclass of *BaseManager* and uses the *register()* classmethod to register new types or callables with the manager class. For example:

```
from multiprocessing.managers import BaseManager

class MathsClass:
    def add(self, x, y):
        return x + y
    def mul(self, x, y):
        return x * y

class MyManager(BaseManager):
    pass

MyManager.register('Maths', MathsClass)

if __name__ == '__main__':
    with MyManager() as manager:
        maths = manager.Maths()
        print(maths.add(4, 3))         # prints 7
        print(maths.mul(7, 8))         # prints 56
```

Using a remote manager

It is possible to run a manager server on one machine and have clients use it from other machines (assuming that the firewalls involved allow it).

Running the following commands creates a server for a single shared queue which remote clients can access:

```
>>> from multiprocessing.managers import BaseManager
>>> from queue import Queue
>>> queue = Queue()
>>> class QueueManager(BaseManager): pass
>>> QueueManager.register('get_queue', callable=lambda:queue)
>>> m = QueueManager(address=('', 50000), authkey=b'abracadabra')
>>> s = m.get_server()
>>> s.serve_forever()
```

One client can access the server as follows:

```
>>> from multiprocessing.managers import BaseManager
>>> class QueueManager(BaseManager): pass
>>> QueueManager.register('get_queue')
>>> m = QueueManager(address=('foo.bar.org', 50000), authkey=b'abracadabra')
>>> m.connect()
>>> queue = m.get_queue()
>>> queue.put('hello')
```

Another client can also use it:

```
>>> from multiprocessing.managers import BaseManager
>>> class QueueManager(BaseManager): pass
>>> QueueManager.register('get_queue')
>>> m = QueueManager(address=('foo.bar.org', 50000), authkey=b'abracadabra')
>>> m.connect()
>>> queue = m.get_queue()
>>> queue.get()
'hello'
```

Local processes can also access that queue, using the code from above on the client to access it remotely:

```
>>> from multiprocessing import Process, Queue
>>> from multiprocessing.managers import BaseManager
>>> class Worker(Process):
...     def __init__(self, q):
...         self.q = q
...         super(Worker, self).__init__()
...     def run(self):
...         self.q.put('local hello')
...
>>> queue = Queue()
>>> w = Worker(queue)
>>> w.start()
>>> class QueueManager(BaseManager): pass
...
>>> QueueManager.register('get_queue', callable=lambda: queue)
>>> m = QueueManager(address=('', 50000), authkey=b'abracadabra')
>>> s = m.get_server()
>>> s.serve_forever()
```

Proxy Objects

A proxy is an object which *refers* to a shared object which lives (presumably) in a different process. The shared object is said to be the *referent* of the proxy. Multiple proxy objects may have the same referent.

A proxy object has methods which invoke corresponding methods of its referent (although not every method of the referent will necessarily be available through the proxy). In this way, a proxy can be used just like its referent can:

```
>>> from multiprocessing import Manager
>>> manager = Manager()
>>> l = manager.list([i*i for i in range(10)])
>>> print(l)
[0, 1, 4, 9, 16, 25, 36, 49, 64, 81]
>>> print(repr(l))
<ListProxy object, typeid 'list' at 0x...>
>>> l[4]
16
>>> l[2:5]
[4, 9, 16]
```

Notice that applying *str()* to a proxy will return the representation of the referent, whereas applying *repr()* will return the representation of the proxy.

An important feature of proxy objects is that they are picklable so they can be passed between processes. As such, a referent can contain *Proxy Objects*. This permits nesting of these managed lists, dicts, and other *Proxy Objects*:

```
>>> a = manager.list()
>>> b = manager.list()
>>> a.append(b)         # referent of a now contains referent of b
>>> print(a, b)
[<ListProxy object, typeid 'list' at ...>] []
>>> b.append('hello')
>>> print(a[0], b)
['hello'] ['hello']
```

Similarly, dict and list proxies may be nested inside one another:

```
>>> l_outer = manager.list([ manager.dict() for i in range(2) ])
>>> d_first_inner = l_outer[0]
>>> d_first_inner['a'] = 1
>>> d_first_inner['b'] = 2
>>> l_outer[1]['c'] = 3
>>> l_outer[1]['z'] = 26
>>> print(l_outer[0])
{'a': 1, 'b': 2}
>>> print(l_outer[1])
{'c': 3, 'z': 26}
```

If standard (non-proxy) *list* or *dict* objects are contained in a referent, modifications to those mutable values will not be propagated through the manager because the proxy has no way of knowing when the values contained within are modified. However, storing a value in a container proxy (which triggers a `__setitem__` on the proxy object) does propagate through the manager and so to effectively modify such an item, one could re-assign the modified value to the container proxy:

```
# create a list proxy and append a mutable object (a dictionary)
lproxy = manager.list()
lproxy.append({})
# now mutate the dictionary
d = lproxy[0]
d['a'] = 1
d['b'] = 2
```

(continues on next page)

(continued from previous page)

```
# at this point, the changes to d are not yet synced, but by
# updating the dictionary, the proxy is notified of the change
lproxy[0] = d
```

This approach is perhaps less convenient than employing nested *Proxy Objects* for most use cases but also demonstrates a level of control over the synchronization.

Note: The proxy types in *multiprocessing* do nothing to support comparisons by value. So, for instance, we have:

```
>>> manager.list([1,2,3]) == [1,2,3]
False
```

One should just use a copy of the referent instead when making comparisons.

---

class multiprocessing.managers.BaseProxy

Proxy objects are instances of subclasses of *BaseProxy*.

_callmethod(*methodname*[, *args*[, *kwds*]])

Call and return the result of a method of the proxy's referent.

If `proxy` is a proxy whose referent is `obj` then the expression

```
proxy._callmethod(methodname, args, kwds)
```

will evaluate the expression

```
getattr(obj, methodname)(*args, **kwds)
```

in the manager's process.

The returned value will be a copy of the result of the call or a proxy to a new shared object – see documentation for the *method_to_typeid* argument of *BaseManager.register()*.

If an exception is raised by the call, then is re-raised by *_callmethod()*. If some other exception is raised in the manager's process then this is converted into a `RemoteError` exception and is raised by *_callmethod()*.

Note in particular that an exception will be raised if *methodname* has not been *exposed*.

An example of the usage of *_callmethod()*:

```
>>> l = manager.list(range(10))
>>> l._callmethod('__len__')
10
>>> l._callmethod('__getitem__', (slice(2, 7),)) # equivalent to l[2:7]
[2, 3, 4, 5, 6]
>>> l._callmethod('__getitem__', (20,))          # equivalent to l[20]
Traceback (most recent call last):
...
IndexError: list index out of range
```

_getvalue()

Return a copy of the referent.

If the referent is unpicklable then this will raise an exception.

__repr__()

Return a representation of the proxy object.

`__str__()`
Return the representation of the referent.

Cleanup

A proxy object uses a weakref callback so that when it gets garbage collected it deregisters itself from the manager which owns its referent.

A shared object gets deleted from the manager process when there are no longer any proxies referring to it.

Process Pools

One can create a pool of processes which will carry out tasks submitted to it with the *Pool* class.

`class multiprocessing.pool.Pool(`[*processes*[, *initializer*[, *initargs*[, *maxtasksperchild*[, *context*]]]]]`)`

A process pool object which controls a pool of worker processes to which jobs can be submitted. It supports asynchronous results with timeouts and callbacks and has a parallel map implementation.

processes is the number of worker processes to use. If *processes* is `None` then the number returned by *os.cpu_count()* is used.

If *initializer* is not `None` then each worker process will call `initializer(*initargs)` when it starts.

maxtasksperchild is the number of tasks a worker process can complete before it will exit and be replaced with a fresh worker process, to enable unused resources to be freed. The default *maxtasksperchild* is `None`, which means worker processes will live as long as the pool.

context can be used to specify the context used for starting the worker processes. Usually a pool is created using the function `multiprocessing.Pool()` or the *Pool()* method of a context object. In both cases *context* is set appropriately.

Note that the methods of the pool object should only be called by the process which created the pool.

New in version 3.2: *maxtasksperchild*

New in version 3.4: *context*

Note: Worker processes within a *Pool* typically live for the complete duration of the Pool's work queue. A frequent pattern found in other systems (such as Apache, mod_wsgi, etc) to free resources held by workers is to allow a worker within a pool to complete only a set amount of work before being exiting, being cleaned up and a new process spawned to replace the old one. The *maxtasksperchild* argument to the *Pool* exposes this ability to the end user.

`apply(`*func*[, *args*[, *kwds*]]`)`
Call *func* with arguments *args* and keyword arguments *kwds*. It blocks until the result is ready. Given this blocks, *apply_async()* is better suited for performing work in parallel. Additionally, *func* is only executed in one of the workers of the pool.

`apply_async(`*func*[, *args*[, *kwds*[, *callback*[, *error_callback*]]]]`)`
A variant of the *apply()* method which returns a result object.

If *callback* is specified then it should be a callable which accepts a single argument. When the result becomes ready *callback* is applied to it, that is unless the call failed, in which case the *error_callback* is applied instead.

If *error_callback* is specified then it should be a callable which accepts a single argument. If the target function fails, then the *error_callback* is called with the exception instance.

Callbacks should complete immediately since otherwise the thread which handles the results will get blocked.

map(*func*, *iterable*[, *chunksize*])
A parallel equivalent of the *map()* built-in function (it supports only one *iterable* argument though). It blocks until the result is ready.

This method chops the iterable into a number of chunks which it submits to the process pool as separate tasks. The (approximate) size of these chunks can be specified by setting *chunksize* to a positive integer.

map_async(*func*, *iterable*[, *chunksize*[, *callback*[, *error_callback*]]])
A variant of the *map()* method which returns a result object.

If *callback* is specified then it should be a callable which accepts a single argument. When the result becomes ready *callback* is applied to it, that is unless the call failed, in which case the *error_callback* is applied instead.

If *error_callback* is specified then it should be a callable which accepts a single argument. If the target function fails, then the *error_callback* is called with the exception instance.

Callbacks should complete immediately since otherwise the thread which handles the results will get blocked.

imap(*func*, *iterable*[, *chunksize*])
A lazier version of *map()*.

The *chunksize* argument is the same as the one used by the *map()* method. For very long iterables using a large value for *chunksize* can make the job complete **much** faster than using the default value of `1`.

Also if *chunksize* is `1` then the `next()` method of the iterator returned by the *imap()* method has an optional *timeout* parameter: `next(timeout)` will raise *multiprocessing.TimeoutError* if the result cannot be returned within *timeout* seconds.

imap_unordered(*func*, *iterable*[, *chunksize*])
The same as *imap()* except that the ordering of the results from the returned iterator should be considered arbitrary. (Only when there is only one worker process is the order guaranteed to be "correct".)

starmap(*func*, *iterable*[, *chunksize*])
Like *map()* except that the elements of the *iterable* are expected to be iterables that are unpacked as arguments.

Hence an *iterable* of `[(1,2), (3, 4)]` results in `[func(1,2), func(3,4)]`.

New in version 3.3.

starmap_async(*func*, *iterable*[, *chunksize*[, *callback*[, *error_callback*]]])
A combination of *starmap()* and *map_async()* that iterates over *iterable* of iterables and calls *func* with the iterables unpacked. Returns a result object.

New in version 3.3.

close()
Prevents any more tasks from being submitted to the pool. Once all the tasks have been completed the worker processes will exit.

terminate()
Stops the worker processes immediately without completing outstanding work. When the pool object is garbage collected *terminate()* will be called immediately.

join()
Wait for the worker processes to exit. One must call *close()* or *terminate()* before using *join()*.

New in version 3.3: Pool objects now support the context management protocol – see *Context Manager Types*. *__enter__()* returns the pool object, and *__exit__()* calls *terminate()*.

class multiprocessing.pool.AsyncResult

The class of the result returned by *Pool.apply_async()* and *Pool.map_async()*.

get([*timeout*])

Return the result when it arrives. If *timeout* is not `None` and the result does not arrive within *timeout* seconds then *multiprocessing.TimeoutError* is raised. If the remote call raised an exception then that exception will be reraised by *get()*.

wait([*timeout*])

Wait until the result is available or until *timeout* seconds pass.

ready()

Return whether the call has completed.

successful()

Return whether the call completed without raising an exception. Will raise *AssertionError* if the result is not ready.

The following example demonstrates the use of a pool:

```
from multiprocessing import Pool
import time

def f(x):
    return x*x

if __name__ == '__main__':
    with Pool(processes=4) as pool:          # start 4 worker processes
        result = pool.apply_async(f, (10,)) # evaluate "f(10)" asynchronously in a single process
        print(result.get(timeout=1))        # prints "100" unless your computer is *very* slow

        print(pool.map(f, range(10)))       # prints "[0, 1, 4,..., 81]"

        it = pool.imap(f, range(10))
        print(next(it))                     # prints "0"
        print(next(it))                     # prints "1"
        print(it.next(timeout=1))           # prints "4" unless your computer is *very* slow

        result = pool.apply_async(time.sleep, (10,))
        print(result.get(timeout=1))        # raises multiprocessing.TimeoutError
```

Listeners and Clients

Usually message passing between processes is done using queues or by using *Connection* objects returned by *Pipe()*.

However, the *multiprocessing.connection* module allows some extra flexibility. It basically gives a high level message oriented API for dealing with sockets or Windows named pipes. It also has support for *digest authentication* using the *hmac* module, and for polling multiple connections at the same time.

multiprocessing.connection.deliver_challenge(*connection*, *authkey*)

Send a randomly generated message to the other end of the connection and wait for a reply.

If the reply matches the digest of the message using *authkey* as the key then a welcome message is sent to the other end of the connection. Otherwise *AuthenticationError* is raised.

multiprocessing.connection.**answer_challenge**(*connection*, *authkey*)
Receive a message, calculate the digest of the message using *authkey* as the key, and then send the digest back.

If a welcome message is not received, then *AuthenticationError* is raised.

multiprocessing.connection.**Client**(*address*[, *family*[, *authkey*]])
Attempt to set up a connection to the listener which is using address *address*, returning a *Connection*.

The type of the connection is determined by *family* argument, but this can generally be omitted since it can usually be inferred from the format of *address*. (See *Address Formats*)

If *authkey* is given and not None, it should be a byte string and will be used as the secret key for an HMAC-based authentication challenge. No authentication is done if *authkey* is None. *AuthenticationError* is raised if authentication fails. See *Authentication keys*.

class multiprocessing.connection.**Listener**([*address*[, *family*[, *backlog*[, *authkey*]]]])
A wrapper for a bound socket or Windows named pipe which is 'listening' for connections.

address is the address to be used by the bound socket or named pipe of the listener object.

Note: If an address of '0.0.0.0' is used, the address will not be a connectable end point on Windows. If you require a connectable end-point, you should use '127.0.0.1'.

---

family is the type of socket (or named pipe) to use. This can be one of the strings `'AF_INET'` (for a TCP socket), `'AF_UNIX'` (for a Unix domain socket) or `'AF_PIPE'` (for a Windows named pipe). Of these only the first is guaranteed to be available. If *family* is `None` then the family is inferred from the format of *address*. If *address* is also `None` then a default is chosen. This default is the family which is assumed to be the fastest available. See *Address Formats*. Note that if *family* is `'AF_UNIX'` and address is `None` then the socket will be created in a private temporary directory created using *tempfile.mkstemp()*.

If the listener object uses a socket then *backlog* (1 by default) is passed to the *listen()* method of the socket once it has been bound.

If *authkey* is given and not None, it should be a byte string and will be used as the secret key for an HMAC-based authentication challenge. No authentication is done if *authkey* is None. *AuthenticationError* is raised if authentication fails. See *Authentication keys*.

accept()
Accept a connection on the bound socket or named pipe of the listener object and return a *Connection* object. If authentication is attempted and fails, then *AuthenticationError* is raised.

close()
Close the bound socket or named pipe of the listener object. This is called automatically when the listener is garbage collected. However it is advisable to call it explicitly.

Listener objects have the following read-only properties:

address
The address which is being used by the Listener object.

last_accepted
The address from which the last accepted connection came. If this is unavailable then it is `None`.

New in version 3.3: Listener objects now support the context management protocol – see *Context Manager Types*. *__enter__()* returns the listener object, and *__exit__()* calls *close()*.

multiprocessing.connection.**wait**(*object_list*, *timeout=None*)
Wait till an object in *object_list* is ready. Returns the list of those objects in *object_list* which are

ready. If *timeout* is a float then the call blocks for at most that many seconds. If *timeout* is `None` then it will block for an unlimited period. A negative timeout is equivalent to a zero timeout.

For both Unix and Windows, an object can appear in *object_list* if it is

- a readable *Connection* object;
- a connected and readable *socket.socket* object; or
- the *sentinel* attribute of a *Process* object.

A connection or socket object is ready when there is data available to be read from it, or the other end has been closed.

Unix: `wait(object_list, timeout)` almost equivalent `select.select(object_list, [], [], timeout)`. The difference is that, if *select.select()* is interrupted by a signal, it can raise *OSError* with an error number of `EINTR`, whereas *wait()* will not.

Windows: An item in *object_list* must either be an integer handle which is waitable (according to the definition used by the documentation of the Win32 function `WaitForMultipleObjects()`) or it can be an object with a `fileno()` method which returns a socket handle or pipe handle. (Note that pipe handles and socket handles are **not** waitable handles.)

New in version 3.3.

Examples

The following server code creates a listener which uses `'secret password'` as an authentication key. It then waits for a connection and sends some data to the client:

```
from multiprocessing.connection import Listener
from array import array

address = ('localhost', 6000)     # family is deduced to be 'AF_INET'

with Listener(address, authkey=b'secret password') as listener:
    with listener.accept() as conn:
        print('connection accepted from', listener.last_accepted)

        conn.send([2.25, None, 'junk', float])

        conn.send_bytes(b'hello')

        conn.send_bytes(array('i', [42, 1729]))
```

The following code connects to the server and receives some data from the server:

```
from multiprocessing.connection import Client
from array import array

address = ('localhost', 6000)

with Client(address, authkey=b'secret password') as conn:
    print(conn.recv())                  # => [2.25, None, 'junk', float]

    print(conn.recv_bytes())            # => 'hello'

    arr = array('i', [0, 0, 0, 0, 0])
    print(conn.recv_bytes_into(arr))    # => 8
    print(arr)                          # => array('i', [42, 1729, 0, 0, 0])
```

The following code uses *wait()* to wait for messages from multiple processes at once:

```
import time, random
from multiprocessing import Process, Pipe, current_process
from multiprocessing.connection import wait

def foo(w):
    for i in range(10):
        w.send((i, current_process().name))
    w.close()

if __name__ == '__main__':
    readers = []

    for i in range(4):
        r, w = Pipe(duplex=False)
        readers.append(r)
        p = Process(target=foo, args=(w,))
        p.start()
        # We close the writable end of the pipe now to be sure that
        # p is the only process which owns a handle for it.  This
        # ensures that when p closes its handle for the writable end,
        # wait() will promptly report the readable end as being ready.
        w.close()

    while readers:
        for r in wait(readers):
            try:
                msg = r.recv()
            except EOFError:
                readers.remove(r)
            else:
                print(msg)
```

Address Formats

- An `'AF_INET'` address is a tuple of the form `(hostname, port)` where *hostname* is a string and *port* is an integer.
- An `'AF_UNIX'` address is a string representing a filename on the filesystem.
- **An `'AF_PIPE'` address is a string of the form `r'\\.\pipe\`*PipeName*`'`.** To use *`Client()`* to connect to a named pipe on a remote computer called *ServerName* one should use an address of the form `r'\\`*ServerName*`\pipe\`*PipeName*`'` instead.

Note that any string beginning with two backslashes is assumed by default to be an `'AF_PIPE'` address rather than an `'AF_UNIX'` address.

Authentication keys

When one uses *`Connection.recv`*, the data received is automatically unpickled. Unfortunately unpickling data from an untrusted source is a security risk. Therefore *`Listener`* and *`Client()`* use the *`hmac`* module to provide digest authentication.

An authentication key is a byte string which can be thought of as a password: once a connection is established both ends will demand proof that the other knows the authentication key. (Demonstrating that both ends are using the same key does **not** involve sending the key over the connection.)

If authentication is requested but no authentication key is specified then the return value of `current_process().authkey` is used (see *Process*). This value will be automatically inherited by any *Process* object that the current process creates. This means that (by default) all processes of a multi-process program will share a single authentication key which can be used when setting up connections between themselves.

Suitable authentication keys can also be generated by using *os.urandom()*.

Logging

Some support for logging is available. Note, however, that the *logging* package does not use process shared locks so it is possible (depending on the handler type) for messages from different processes to get mixed up.

`multiprocessing.get_logger()`
Returns the logger used by *multiprocessing*. If necessary, a new one will be created.

When first created the logger has level `logging.NOTSET` and no default handler. Messages sent to this logger will not by default propagate to the root logger.

Note that on Windows child processes will only inherit the level of the parent process's logger – any other customization of the logger will not be inherited.

`multiprocessing.log_to_stderr()`
This function performs a call to *get_logger()* but in addition to returning the logger created by get_logger, it adds a handler which sends output to *sys.stderr* using format `'[%(levelname)s/%(processName)s] %(message)s'`.

Below is an example session with logging turned on:

```
>>> import multiprocessing, logging
>>> logger = multiprocessing.log_to_stderr()
>>> logger.setLevel(logging.INFO)
>>> logger.warning('doomed')
[WARNING/MainProcess] doomed
>>> m = multiprocessing.Manager()
[INFO/SyncManager-...] child process calling self.run()
[INFO/SyncManager-...] created temp directory /.../pymp-...
[INFO/SyncManager-...] manager serving at '/.../listener-...'
>>> del m
[INFO/MainProcess] sending shutdown message to manager
[INFO/SyncManager-...] manager exiting with exitcode 0
```

For a full table of logging levels, see the *logging* module.

The `multiprocessing.dummy` module

multiprocessing.dummy replicates the API of *multiprocessing* but is no more than a wrapper around the *threading* module.

17.2.3 Programming guidelines

There are certain guidelines and idioms which should be adhered to when using *multiprocessing*.

All start methods

The following applies to all start methods.

Avoid shared state

As far as possible one should try to avoid shifting large amounts of data between processes.

It is probably best to stick to using queues or pipes for communication between processes rather than using the lower level synchronization primitives.

Picklability

Ensure that the arguments to the methods of proxies are picklable.

Thread safety of proxies

Do not use a proxy object from more than one thread unless you protect it with a lock.

(There is never a problem with different processes using the *same* proxy.)

Joining zombie processes

On Unix when a process finishes but has not been joined it becomes a zombie. There should never be very many because each time a new process starts (or *active_children()* is called) all completed processes which have not yet been joined will be joined. Also calling a finished process's *Process.is_alive* will join the process. Even so it is probably good practice to explicitly join all the processes that you start.

Better to inherit than pickle/unpickle

When using the *spawn* or *forkserver* start methods many types from *multiprocessing* need to be picklable so that child processes can use them. However, one should generally avoid sending shared objects to other processes using pipes or queues. Instead you should arrange the program so that a process which needs access to a shared resource created elsewhere can inherit it from an ancestor process.

Avoid terminating processes

Using the *Process.terminate* method to stop a process is liable to cause any shared resources (such as locks, semaphores, pipes and queues) currently being used by the process to become broken or unavailable to other processes.

Therefore it is probably best to only consider using *Process.terminate* on processes which never use any shared resources.

Joining processes that use queues

Bear in mind that a process that has put items in a queue will wait before terminating until all the buffered items are fed by the "feeder" thread to the underlying pipe. (The child process can call the *Queue.cancel_join_thread* method of the queue to avoid this behaviour.)

This means that whenever you use a queue you need to make sure that all items which have been put on the queue will eventually be removed before the process is joined. Otherwise you cannot be sure that processes which have put items on the queue will terminate. Remember also that non-daemonic processes will be joined automatically.

An example which will deadlock is the following:

```
from multiprocessing import Process, Queue

def f(q):
    q.put('X' * 1000000)

if __name__ == '__main__':
```

(continues on next page)

(continued from previous page)

```
    queue = Queue()
    p = Process(target=f, args=(queue,))
    p.start()
    p.join()                    # this deadlocks
    obj = queue.get()
```

A fix here would be to swap the last two lines (or simply remove the `p.join()` line).

Explicitly pass resources to child processes

On Unix using the *fork* start method, a child process can make use of a shared resource created in a parent process using a global resource. However, it is better to pass the object as an argument to the constructor for the child process.

Apart from making the code (potentially) compatible with Windows and the other start methods this also ensures that as long as the child process is still alive the object will not be garbage collected in the parent process. This might be important if some resource is freed when the object is garbage collected in the parent process.

So for instance

```
from multiprocessing import Process, Lock

def f():
    ... do something using "lock" ...

if __name__ == '__main__':
    lock = Lock()
    for i in range(10):
        Process(target=f).start()
```

should be rewritten as

```
from multiprocessing import Process, Lock

def f(l):
    ... do something using "l" ...

if __name__ == '__main__':
    lock = Lock()
    for i in range(10):
        Process(target=f, args=(lock,)).start()
```

Beware of replacing *sys.stdin* with a "file like object"

multiprocessing originally unconditionally called:

```
os.close(sys.stdin.fileno())
```

in the `multiprocessing.Process._bootstrap()` method — this resulted in issues with processes-in-processes. This has been changed to:

```
sys.stdin.close()
sys.stdin = open(os.open(os.devnull, os.O_RDONLY), closefd=False)
```

Which solves the fundamental issue of processes colliding with each other resulting in a bad file descriptor error, but introduces a potential danger to applications which replace *sys.stdin()* with a "file-like object" with output buffering. This danger is that if multiple processes call

close() on this file-like object, it could result in the same data being flushed to the object multiple times, resulting in corruption.

If you write a file-like object and implement your own caching, you can make it fork-safe by storing the pid whenever you append to the cache, and discarding the cache when the pid changes. For example:

```
@property
def cache(self):
    pid = os.getpid()
    if pid != self._pid:
        self._pid = pid
        self._cache = []
    return self._cache
```

For more information, see bpo-5155, bpo-5313 and bpo-5331

The *spawn* and *forkserver* start methods

There are a few extra restriction which don't apply to the *fork* start method.

More picklability

Ensure that all arguments to `Process.__init__()` are picklable. Also, if you subclass *Process* then make sure that instances will be picklable when the *Process.start* method is called.

Global variables

Bear in mind that if code run in a child process tries to access a global variable, then the value it sees (if any) may not be the same as the value in the parent process at the time that *Process.start* was called.

However, global variables which are just module level constants cause no problems.

Safe importing of main module

Make sure that the main module can be safely imported by a new Python interpreter without causing unintended side effects (such a starting a new process).

For example, using the *spawn* or *forkserver* start method running the following module would fail with a *RuntimeError*:

```
from multiprocessing import Process

def foo():
    print('hello')

p = Process(target=foo)
p.start()
```

Instead one should protect the "entry point" of the program by using `if __name__ == '__main__':` as follows:

```
from multiprocessing import Process, freeze_support, set_start_method

def foo():
    print('hello')

if __name__ == '__main__':
    freeze_support()
```

(continues on next page)

(continued from previous page)

```
    set_start_method('spawn')
    p = Process(target=foo)
    p.start()
```

(The `freeze_support()` line can be omitted if the program will be run normally instead of frozen.)

This allows the newly spawned Python interpreter to safely import the module and then run the module's `foo()` function.

Similar restrictions apply if a pool or manager is created in the main module.

17.2.4 Examples

Demonstration of how to create and use customized managers and proxies:

```
from multiprocessing import freeze_support
from multiprocessing.managers import BaseManager, BaseProxy
import operator

##

class Foo:
    def f(self):
        print('you called Foo.f()')
    def g(self):
        print('you called Foo.g()')
    def _h(self):
        print('you called Foo._h()')

# A simple generator function
def baz():
    for i in range(10):
        yield i*i

# Proxy type for generator objects
class GeneratorProxy(BaseProxy):
    _exposed_ = ['__next__']
    def __iter__(self):
        return self
    def __next__(self):
        return self._callmethod('__next__')

# Function to return the operator module
def get_operator_module():
    return operator

##

class MyManager(BaseManager):
    pass

# register the Foo class; make `f()` and `g()` accessible via proxy
MyManager.register('Foo1', Foo)

# register the Foo class; make `g()` and `_h()` accessible via proxy
```

(continues on next page)

(continued from previous page)

```
MyManager.register('Foo2', Foo, exposed=('g', '_h'))

# register the generator function baz; use `GeneratorProxy` to make proxies
MyManager.register('baz', baz, proxytype=GeneratorProxy)

# register get_operator_module(); make public functions accessible via proxy
MyManager.register('operator', get_operator_module)

##

def test():
    manager = MyManager()
    manager.start()

    print('-' * 20)

    f1 = manager.Foo1()
    f1.f()
    f1.g()
    assert not hasattr(f1, '_h')
    assert sorted(f1._exposed_) == sorted(['f', 'g'])

    print('-' * 20)

    f2 = manager.Foo2()
    f2.g()
    f2._h()
    assert not hasattr(f2, 'f')
    assert sorted(f2._exposed_) == sorted(['g', '_h'])

    print('-' * 20)

    it = manager.baz()
    for i in it:
        print('<%d>' % i, end=' ')
    print()

    print('-' * 20)

    op = manager.operator()
    print('op.add(23, 45) =', op.add(23, 45))
    print('op.pow(2, 94) =', op.pow(2, 94))
    print('op._exposed_ =', op._exposed_)

##

if __name__ == '__main__':
    freeze_support()
    test()
```

Using *Pool*:

```
import multiprocessing
import time
import random
import sys
```

(continues on next page)

(continued from previous page)

```
#
# Functions used by test code
#

def calculate(func, args):

if __name__ == '__main__':
    multiprocessing.freeze_support()
    test()
```

An example showing how to use queues to feed tasks to a collection of worker processes and collect the results:

```
import time
import random

from multiprocessing import Process, Queue, current_process, freeze_support

#
# Function run by worker processes
#

def worker(input, output):
    for func, args in iter(input.get, 'STOP'):
        result = calculate(func, args)
        output.put(result)

#
```

(continues on next page)

(continued from previous page)

```
# Function used to calculate result
#

def calculate(func, args):
    result = func(*args)
    return '%s says that %s%s = %s' % \
        (current_process().name, func.__name__, args, result)

#
# Functions referenced by tasks
#

def mul(a, b):
    time.sleep(0.5*random.random())
    return a * b

def plus(a, b):
    time.sleep(0.5*random.random())
    return a + b

#
#
#

def test():
    NUMBER_OF_PROCESSES = 4
    TASKS1 = [(mul, (i, 7)) for i in range(20)]
    TASKS2 = [(plus, (i, 8)) for i in range(10)]

    # Create queues
    task_queue = Queue()
    done_queue = Queue()

    # Submit tasks
    for task in TASKS1:
        task_queue.put(task)

    # Start worker processes
    for i in range(NUMBER_OF_PROCESSES):
        Process(target=worker, args=(task_queue, done_queue)).start()

    # Get and print results
    print('Unordered results:')
    for i in range(len(TASKS1)):
        print('\t', done_queue.get())

    # Add more tasks using `put()`
    for task in TASKS2:
        task_queue.put(task)

    # Get and print some more results
    for i in range(len(TASKS2)):
        print('\t', done_queue.get())

    # Tell child processes to stop
    for i in range(NUMBER_OF_PROCESSES):
```

(continues on next page)

(continued from previous page)

```
        task_queue.put('STOP')

if __name__ == '__main__':
    freeze_support()
    test()
```

17.3 The concurrent package

Currently, there is only one module in this package:

- *concurrent.futures* – Launching parallel tasks

17.4 concurrent.futures — Launching parallel tasks

New in version 3.2.

Source code: Lib/concurrent/futures/thread.py and Lib/concurrent/futures/process.py

---

The *concurrent.futures* module provides a high-level interface for asynchronously executing callables.

The asynchronous execution can be performed with threads, using *ThreadPoolExecutor*, or separate processes, using *ProcessPoolExecutor*. Both implement the same interface, which is defined by the abstract *Executor* class.

17.4.1 Executor Objects

class concurrent.futures.Executor

An abstract class that provides methods to execute calls asynchronously. It should not be used directly, but through its concrete subclasses.

submit(*fn*, **args*, ***kwargs*)

Schedules the callable, *fn*, to be executed as `fn(*args **kwargs)` and returns a *Future* object representing the execution of the callable.

```
with ThreadPoolExecutor(max_workers=1) as executor:
    future = executor.submit(pow, 323, 1235)
    print(future.result())
```

map(*func*, **iterables*, *timeout=None*, *chunksize=1*)

Similar to *map(func, *iterables)* except:

- the *iterables* are collected immediately rather than lazily;
- *func* is executed asynchronously and several calls to *func* may be made concurrently.

The returned iterator raises a *concurrent.futures.TimeoutError* if *__next__()* is called and the result isn't available after *timeout* seconds from the original call to *Executor.map()*. *timeout* can be an int or a float. If *timeout* is not specified or `None`, there is no limit to the wait time.

If a *func* call raises an exception, then that exception will be raised when its value is retrieved from the iterator.

When using *ProcessPoolExecutor*, this method chops *iterables* into a number of chunks which it submits to the pool as separate tasks. The (approximate) size of these chunks can be specified by setting *chunksize* to a positive integer. For very long iterables, using a large value for *chunksize* can significantly improve performance compared to the default size of 1. With *ThreadPoolExecutor*, *chunksize* has no effect.

Changed in version 3.5: Added the *chunksize* argument.

shutdown(*wait=True*)

Signal the executor that it should free any resources that it is using when the currently pending futures are done executing. Calls to *Executor.submit()* and *Executor.map()* made after shutdown will raise *RuntimeError*.

If *wait* is `True` then this method will not return until all the pending futures are done executing and the resources associated with the executor have been freed. If *wait* is `False` then this method will return immediately and the resources associated with the executor will be freed when all pending futures are done executing. Regardless of the value of *wait*, the entire Python program will not exit until all pending futures are done executing.

You can avoid having to call this method explicitly if you use the `with` statement, which will shutdown the *Executor* (waiting as if *Executor.shutdown()* were called with *wait* set to `True`):

```
import shutil
with ThreadPoolExecutor(max_workers=4) as e:
    e.submit(shutil.copy, 'src1.txt', 'dest1.txt')
    e.submit(shutil.copy, 'src2.txt', 'dest2.txt')
    e.submit(shutil.copy, 'src3.txt', 'dest3.txt')
    e.submit(shutil.copy, 'src4.txt', 'dest4.txt')
```

17.4.2 ThreadPoolExecutor

ThreadPoolExecutor is an *Executor* subclass that uses a pool of threads to execute calls asynchronously.

Deadlocks can occur when the callable associated with a *Future* waits on the results of another *Future*. For example:

```
import time
def wait_on_b():
    time.sleep(5)
    print(b.result())  # b will never complete because it is waiting on a.
    return 5

def wait_on_a():
    time.sleep(5)
    print(a.result())  # a will never complete because it is waiting on b.
    return 6

executor = ThreadPoolExecutor(max_workers=2)
a = executor.submit(wait_on_b)
b = executor.submit(wait_on_a)
```

And:

```
def wait_on_future():
    f = executor.submit(pow, 5, 2)
    # This will never complete because there is only one worker thread and
    # it is executing this function.
    print(f.result())

executor = ThreadPoolExecutor(max_workers=1)
executor.submit(wait_on_future)
```

class concurrent.futures.**ThreadPoolExecutor**(*max_workers=None*, *thread_name_prefix=''*, *initializer=None*, *initargs=()*)

An *Executor* subclass that uses a pool of at most *max_workers* threads to execute calls asynchronously.

initializer is an optional callable that is called at the start of each worker thread; *initargs* is a tuple of arguments passed to the initializer. Should *initializer* raise an exception, all currently pending jobs will raise a *BrokenThreadPool*, as well any attempt to submit more jobs to the pool.

Changed in version 3.5: If *max_workers* is `None` or not given, it will default to the number of processors on the machine, multiplied by `5`, assuming that *ThreadPoolExecutor* is often used to overlap I/O instead of CPU work and the number of workers should be higher than the number of workers for *ProcessPoolExecutor*.

New in version 3.6: The *thread_name_prefix* argument was added to allow users to control the threading.Thread names for worker threads created by the pool for easier debugging.

Changed in version 3.7: Added the *initializer* and *initargs* arguments.

ThreadPoolExecutor Example

```
import concurrent.futures
import urllib.request

URLS = ['http://www.foxnews.com/',
        'http://www.cnn.com/',
        'http://europe.wsj.com/',
        'http://www.bbc.co.uk/',
        'http://some-made-up-domain.com/']

# Retrieve a single page and report the URL and contents
def load_url(url, timeout):
    with urllib.request.urlopen(url, timeout=timeout) as conn:
        return conn.read()

# We can use a with statement to ensure threads are cleaned up promptly
with concurrent.futures.ThreadPoolExecutor(max_workers=5) as executor:
    # Start the load operations and mark each future with its URL
    future_to_url = {executor.submit(load_url, url, 60): url for url in URLS}
    for future in concurrent.futures.as_completed(future_to_url):
        url = future_to_url[future]
        try:
            data = future.result()
        except Exception as exc:
            print('%r generated an exception: %s' % (url, exc))
        else:
            print('%r page is %d bytes' % (url, len(data)))
```

17.4.3 ProcessPoolExecutor

The *ProcessPoolExecutor* class is an *Executor* subclass that uses a pool of processes to execute calls asynchronously. *ProcessPoolExecutor* uses the *multiprocessing* module, which allows it to side-step the *Global Interpreter Lock* but also means that only picklable objects can be executed and returned.

The `__main__` module must be importable by worker subprocesses. This means that *ProcessPoolExecutor* will not work in the interactive interpreter.

Calling *Executor* or *Future* methods from a callable submitted to a *ProcessPoolExecutor* will result in deadlock.

class concurrent.futures.**ProcessPoolExecutor**(*max_workers=None*, *mp_context=None*, *initializer=None*, *initargs=()*)

An *Executor* subclass that executes calls asynchronously using a pool of at most *max_workers* processes. If *max_workers* is `None` or not given, it will default to the number of processors on the machine. If *max_workers* is lower or equal to `0`, then a *ValueError* will be raised. *mp_context* can be a multiprocessing context or None. It will be used to launch the workers. If *mp_context* is `None` or not given, the default multiprocessing context is used.

initializer is an optional callable that is called at the start of each worker process; *initargs* is a tuple of arguments passed to the initializer. Should *initializer* raise an exception, all currently pending jobs will raise a *BrokenThreadPool*, as well any attempt to submit more jobs to the pool.

Changed in version 3.3: When one of the worker processes terminates abruptly, a `BrokenProcessPool` error is now raised. Previously, behaviour was undefined but operations on the executor or its futures would often freeze or deadlock.

Changed in version 3.7: The *mp_context* argument was added to allow users to control the start_method for worker processes created by the pool.

Added the *initializer* and *initargs* arguments.

ProcessPoolExecutor Example

```
import concurrent.futures
import math

PRIMES = [
    112272535095293,
    112582705942171,
    112272535095293,
    115280095190773,
    115797848077099,
    1099726899285419]

def is_prime(n):
    if n % 2 == 0:
        return False

    sqrt_n = int(math.floor(math.sqrt(n)))
    for i in range(3, sqrt_n + 1, 2):
        if n % i == 0:
            return False
    return True

def main():
    with concurrent.futures.ProcessPoolExecutor() as executor:
```

(continues on next page)

(continued from previous page)

```
        for number, prime in zip(PRIMES, executor.map(is_prime, PRIMES)):
            print('%d is prime: %s' % (number, prime))

if __name__ == '__main__':
    main()
```

17.4.4 Future Objects

The *Future* class encapsulates the asynchronous execution of a callable. *Future* instances are created by *Executor.submit()*.

class concurrent.futures.Future

Encapsulates the asynchronous execution of a callable. *Future* instances are created by *Executor.submit()* and should not be created directly except for testing.

cancel()

Attempt to cancel the call. If the call is currently being executed and cannot be cancelled then the method will return `False`, otherwise the call will be cancelled and the method will return `True`.

cancelled()

Return `True` if the call was successfully cancelled.

running()

Return `True` if the call is currently being executed and cannot be cancelled.

done()

Return `True` if the call was successfully cancelled or finished running.

result(*timeout=None*)

Return the value returned by the call. If the call hasn't yet completed then this method will wait up to *timeout* seconds. If the call hasn't completed in *timeout* seconds, then a *concurrent.futures.TimeoutError* will be raised. *timeout* can be an int or float. If *timeout* is not specified or `None`, there is no limit to the wait time.

If the future is cancelled before completing then *CancelledError* will be raised.

If the call raised, this method will raise the same exception.

exception(*timeout=None*)

Return the exception raised by the call. If the call hasn't yet completed then this method will wait up to *timeout* seconds. If the call hasn't completed in *timeout* seconds, then a *concurrent.futures.TimeoutError* will be raised. *timeout* can be an int or float. If *timeout* is not specified or `None`, there is no limit to the wait time.

If the future is cancelled before completing then *CancelledError* will be raised.

If the call completed without raising, `None` is returned.

add_done_callback(*fn*)

Attaches the callable *fn* to the future. *fn* will be called, with the future as its only argument, when the future is cancelled or finishes running.

Added callables are called in the order that they were added and are always called in a thread belonging to the process that added them. If the callable raises an *Exception* subclass, it will be logged and ignored. If the callable raises a *BaseException* subclass, the behavior is undefined.

If the future has already completed or been cancelled, *fn* will be called immediately.

The following *Future* methods are meant for use in unit tests and *Executor* implementations.

set_running_or_notify_cancel()
This method should only be called by *Executor* implementations before executing the work associated with the *Future* and by unit tests.

If the method returns `False` then the *Future* was cancelled, i.e. *Future.cancel()* was called and returned *True*. Any threads waiting on the *Future* completing (i.e. through *as_completed()* or *wait()*) will be woken up.

If the method returns `True` then the *Future* was not cancelled and has been put in the running state, i.e. calls to *Future.running()* will return *True*.

This method can only be called once and cannot be called after *Future.set_result()* or *Future.set_exception()* have been called.

set_result(*result*)
Sets the result of the work associated with the *Future* to *result*.

This method should only be used by *Executor* implementations and unit tests.

set_exception(*exception*)
Sets the result of the work associated with the *Future* to the *Exception* *exception*.

This method should only be used by *Executor* implementations and unit tests.

17.4.5 Module Functions

concurrent.futures.**wait**(*fs*, *timeout=None*, *return_when=ALL_COMPLETED*)
Wait for the *Future* instances (possibly created by different *Executor* instances) given by *fs* to complete. Returns a named 2-tuple of sets. The first set, named `done`, contains the futures that completed (finished or were cancelled) before the wait completed. The second set, named `not_done`, contains uncompleted futures.

timeout can be used to control the maximum number of seconds to wait before returning. *timeout* can be an int or float. If *timeout* is not specified or `None`, there is no limit to the wait time.

return_when indicates when this function should return. It must be one of the following constants:

Constant	Description
`FIRST_COMPLETED`	The function will return when any future finishes or is cancelled.
`FIRST_EXCEPTION`	The function will return when any future finishes by raising an exception. If no future raises an exception then it is equivalent to `ALL_COMPLETED`.
`ALL_COMPLETED`	The function will return when all futures finish or are cancelled.

concurrent.futures.**as_completed**(*fs*, *timeout=None*)
Returns an iterator over the *Future* instances (possibly created by different *Executor* instances) given by *fs* that yields futures as they complete (finished or were cancelled). Any futures given by *fs* that are duplicated will be returned once. Any futures that completed before *as_completed()* is called will be yielded first. The returned iterator raises a *concurrent.futures.TimeoutError* if *__next__()* is called and the result isn't available after *timeout* seconds from the original call to *as_completed()*. *timeout* can be an int or float. If *timeout* is not specified or `None`, there is no limit to the wait time.

See also:

PEP 3148 – **futures - execute computations asynchronously** The proposal which described this feature for inclusion in the Python standard library.

17.4.6 Exception classes

exception concurrent.futures.**CancelledError**
Raised when a future is cancelled.

exception concurrent.futures.**TimeoutError**
Raised when a future operation exceeds the given timeout.

exception concurrent.futures.**BrokenExecutor**
Derived from *RuntimeError*, this exception class is raised when an executor is broken for some reason, and cannot be used to submit or execute new tasks.

New in version 3.7.

exception concurrent.futures.thread.**BrokenThreadPool**
Derived from *BrokenExecutor*, this exception class is raised when one of the workers of a ThreadPoolExecutor has failed initializing.

New in version 3.7.

exception concurrent.futures.process.**BrokenProcessPool**
Derived from *BrokenExecutor* (formerly *RuntimeError*), this exception class is raised when one of the workers of a ProcessPoolExecutor has terminated in a non-clean fashion (for example, if it was killed from the outside).

New in version 3.3.

17.5 subprocess — Subprocess management

Source code: Lib/subprocess.py

The *subprocess* module allows you to spawn new processes, connect to their input/output/error pipes, and obtain their return codes. This module intends to replace several older modules and functions:

```
os.system
os.spawn*
```

Information about how the *subprocess* module can be used to replace these modules and functions can be found in the following sections.

See also:

PEP 324 – PEP proposing the subprocess module

17.5.1 Using the subprocess Module

The recommended approach to invoking subprocesses is to use the *run()* function for all use cases it can handle. For more advanced use cases, the underlying *Popen* interface can be used directly.

The *run()* function was added in Python 3.5; if you need to retain compatibility with older versions, see the *Older high-level API* section.

subprocess.**run**(*args*, ***, *stdin=None*, *input=None*, *stdout=None*, *stderr=None*, *shell=False*, *cwd=None*, *timeout=None*, *check=False*, *encoding=None*, *errors=None*, *text=None*, *env=None*)
Run the command described by *args*. Wait for command to complete, then return a *CompletedProcess* instance.

The arguments shown above are merely the most common ones, described below in *Frequently Used Arguments* (hence the use of keyword-only notation in the abbreviated signature). The full function signature is largely the same as that of the *Popen* constructor - most of the arguments to this function are passed through to that interface. (*timeout*, *input*, *check*, and *capture_output* are not.)

If *capture_output* is true, stdout and stderr will be captured. When used, the internal *Popen* object is automatically created with `stdout=PIPE` and `stderr=PIPE`. The *stdout* and *stderr* arguments may not be used as well.

The *timeout* argument is passed to *Popen.communicate()*. If the timeout expires, the child process will be killed and waited for. The *TimeoutExpired* exception will be re-raised after the child process has terminated.

The *input* argument is passed to *Popen.communicate()* and thus to the subprocess's stdin. If used it must be a byte sequence, or a string if *encoding* or *errors* is specified or *text* is true. When used, the internal *Popen* object is automatically created with `stdin=PIPE`, and the *stdin* argument may not be used as well.

If *check* is true, and the process exits with a non-zero exit code, a *CalledProcessError* exception will be raised. Attributes of that exception hold the arguments, the exit code, and stdout and stderr if they were captured.

If *encoding* or *errors* are specified, or *text* is true, file objects for stdin, stdout and stderr are opened in text mode using the specified *encoding* and *errors* or the *io.TextIOWrapper* default. The *universal_newlines* argument is equivalent to *text* and is provided for backwards compatibility. By default, file objects are opened in binary mode.

If *env* is not `None`, it must be a mapping that defines the environment variables for the new process; these are used instead of the default behavior of inheriting the current process' environment. It is passed directly to *Popen*.

Examples:

```
>>> subprocess.run(["ls", "-l"])  # doesn't capture output
CompletedProcess(args=['ls', '-l'], returncode=0)

>>> subprocess.run("exit 1", shell=True, check=True)
Traceback (most recent call last):
  ...
subprocess.CalledProcessError: Command 'exit 1' returned non-zero exit status 1

>>> subprocess.run(["ls", "-l", "/dev/null"], capture_output=True)
CompletedProcess(args=['ls', '-l', '/dev/null'], returncode=0,
stdout=b'crw-rw-rw- 1 root root 1, 3 Jan 23 16:23 /dev/null\n', stderr=b'')
```

New in version 3.5.

Changed in version 3.6: Added *encoding* and *errors* parameters

Changed in version 3.7: Added the *text* parameter, as a more understandable alias of *universal_newlines*. Added the *capture_output* parameter.

class subprocess.CompletedProcess

The return value from *run()*, representing a process that has finished.

args

The arguments used to launch the process. This may be a list or a string.

returncode

Exit status of the child process. Typically, an exit status of 0 indicates that it ran successfully.

A negative value `-N` indicates that the child was terminated by signal `N` (POSIX only).

stdout
Captured stdout from the child process. A bytes sequence, or a string if *run()* was called with an encoding, errors, or text=True. `None` if stdout was not captured.

If you ran the process with `stderr=subprocess.STDOUT`, stdout and stderr will be combined in this attribute, and *stderr* will be `None`.

stderr
Captured stderr from the child process. A bytes sequence, or a string if *run()* was called with an encoding, errors, or text=True. `None` if stderr was not captured.

check_returncode()
If *returncode* is non-zero, raise a *CalledProcessError*.

New in version 3.5.

subprocess.DEVNULL
Special value that can be used as the *stdin*, *stdout* or *stderr* argument to *Popen* and indicates that the special file *os.devnull* will be used.

New in version 3.3.

subprocess.PIPE
Special value that can be used as the *stdin*, *stdout* or *stderr* argument to *Popen* and indicates that a pipe to the standard stream should be opened. Most useful with *Popen.communicate()*.

subprocess.STDOUT
Special value that can be used as the *stderr* argument to *Popen* and indicates that standard error should go into the same handle as standard output.

exception subprocess.SubprocessError
Base class for all other exceptions from this module.

New in version 3.3.

exception subprocess.TimeoutExpired
Subclass of *SubprocessError*, raised when a timeout expires while waiting for a child process.

cmd
Command that was used to spawn the child process.

timeout
Timeout in seconds.

output
Output of the child process if it was captured by *run()* or *check_output()*. Otherwise, `None`.

stdout
Alias for output, for symmetry with *stderr*.

stderr
Stderr output of the child process if it was captured by *run()*. Otherwise, `None`.

New in version 3.3.

Changed in version 3.5: *stdout* and *stderr* attributes added

exception subprocess.CalledProcessError
Subclass of *SubprocessError*, raised when a process run by *check_call()* or *check_output()* returns a non-zero exit status.

returncode
Exit status of the child process. If the process exited due to a signal, this will be the negative signal number.

cmd
Command that was used to spawn the child process.

output
Output of the child process if it was captured by *run()* or *check_output()*. Otherwise, None.

stdout
Alias for output, for symmetry with *stderr*.

stderr
Stderr output of the child process if it was captured by *run()*. Otherwise, None.

Changed in version 3.5: *stdout* and *stderr* attributes added

Frequently Used Arguments

To support a wide variety of use cases, the *Popen* constructor (and the convenience functions) accept a large number of optional arguments. For most typical use cases, many of these arguments can be safely left at their default values. The arguments that are most commonly needed are:

args is required for all calls and should be a string, or a sequence of program arguments. Providing a sequence of arguments is generally preferred, as it allows the module to take care of any required escaping and quoting of arguments (e.g. to permit spaces in file names). If passing a single string, either *shell* must be *True* (see below) or else the string must simply name the program to be executed without specifying any arguments.

stdin, *stdout* and *stderr* specify the executed program's standard input, standard output and standard error file handles, respectively. Valid values are *PIPE*, *DEVNULL*, an existing file descriptor (a positive integer), an existing file object, and None. *PIPE* indicates that a new pipe to the child should be created. *DEVNULL* indicates that the special file *os.devnull* will be used. With the default settings of None, no redirection will occur; the child's file handles will be inherited from the parent. Additionally, *stderr* can be *STDOUT*, which indicates that the stderr data from the child process should be captured into the same file handle as for *stdout*.

If *encoding* or *errors* are specified, or *text* (also known as *universal_newlines*) is true, the file objects *stdin*, *stdout* and *stderr* will be opened in text mode using the *encoding* and *errors* specified in the call or the defaults for *io.TextIOWrapper*.

For *stdin*, line ending characters '\n' in the input will be converted to the default line separator *os.linesep*. For *stdout* and *stderr*, all line endings in the output will be converted to '\n'. For more information see the documentation of the *io.TextIOWrapper* class when the *newline* argument to its constructor is None.

If text mode is not used, *stdin*, *stdout* and *stderr* will be opened as binary streams. No encoding or line ending conversion is performed.

New in version 3.6: Added *encoding* and *errors* parameters.

New in version 3.7: Added the *text* parameter as an alias for *universal_newlines*.

Note: The newlines attribute of the file objects *Popen.stdin*, *Popen.stdout* and *Popen.stderr* are not updated by the *Popen.communicate()* method.

If *shell* is True, the specified command will be executed through the shell. This can be useful if you are using Python primarily for the enhanced control flow it offers over most system shells and still want convenient access to other shell features such as shell pipes, filename wildcards, environment variable expansion, and expansion of ~ to a user's home directory. However, note that Python itself offers implementations of many shell-like features (in particular, *glob*, *fnmatch*, *os.walk()*, *os.path.expandvars()*, *os.path.expanduser()*, and *shutil*).

Changed in version 3.3: When *universal_newlines* is `True`, the class uses the encoding *locale.getpreferredencoding(False)* instead of `locale.getpreferredencoding()`. See the *io.TextIOWrapper* class for more information on this change.

Note: Read the *Security Considerations* section before using `shell=True`.

These options, along with all of the other options, are described in more detail in the *Popen* constructor documentation.

Popen Constructor

The underlying process creation and management in this module is handled by the *Popen* class. It offers a lot of flexibility so that developers are able to handle the less common cases not covered by the convenience functions.

`class subprocess.Popen`(*args*, *bufsize=-1*, *executable=None*, *stdin=None*, *stdout=None*, *stderr=None*, *preexec_fn=None*, *close_fds=True*, *shell=False*, *cwd=None*, *env=None*, *universal_newlines=False*, *startupinfo=None*, *creationflags=0*, *restore_signals=True*, *start_new_session=False*, *pass_fds=()*, ***, *encoding=None*, *errors=None*, *text=None*)

Execute a child program in a new process. On POSIX, the class uses *os.execvp()*-like behavior to execute the child program. On Windows, the class uses the Windows `CreateProcess()` function. The arguments to *Popen* are as follows.

args should be a sequence of program arguments or else a single string. By default, the program to execute is the first item in *args* if *args* is a sequence. If *args* is a string, the interpretation is platform-dependent and described below. See the *shell* and *executable* arguments for additional differences from the default behavior. Unless otherwise stated, it is recommended to pass *args* as a sequence.

On POSIX, if *args* is a string, the string is interpreted as the name or path of the program to execute. However, this can only be done if not passing arguments to the program.

Note: *shlex.split()* can be useful when determining the correct tokenization for *args*, especially in complex cases:

```
>>> import shlex, subprocess
>>> command_line = input()
/bin/vikings -input eggs.txt -output "spam spam.txt" -cmd "echo '$MONEY'"
>>> args = shlex.split(command_line)
>>> print(args)
['/bin/vikings', '-input', 'eggs.txt', '-output', 'spam spam.txt', '-cmd', "echo '$MONEY'"]
>>> p = subprocess.Popen(args) # Success!
```

Note in particular that options (such as *-input*) and arguments (such as *eggs.txt*) that are separated by whitespace in the shell go in separate list elements, while arguments that need quoting or backslash escaping when used in the shell (such as filenames containing spaces or the *echo* command shown above) are single list elements.

On Windows, if *args* is a sequence, it will be converted to a string in a manner described in *Converting an argument sequence to a string on Windows*. This is because the underlying `CreateProcess()` operates on strings.

The *shell* argument (which defaults to `False`) specifies whether to use the shell as the program to execute. If *shell* is `True`, it is recommended to pass *args* as a string rather than as a sequence.

On POSIX with `shell=True`, the shell defaults to `/bin/sh`. If *args* is a string, the string specifies the command to execute through the shell. This means that the string must be formatted exactly as it would be when typed at the shell prompt. This includes, for example, quoting or backslash escaping filenames with spaces in them. If *args* is a sequence, the first item specifies the command string, and any additional items will be treated as additional arguments to the shell itself. That is to say, *Popen* does the equivalent of:

```
Popen(['/bin/sh', '-c', args[0], args[1], ...])
```

On Windows with `shell=True`, the `COMSPEC` environment variable specifies the default shell. The only time you need to specify `shell=True` on Windows is when the command you wish to execute is built into the shell (e.g. `dir` or `copy`). You do not need `shell=True` to run a batch file or console-based executable.

Note: Read the *Security Considerations* section before using `shell=True`.

---

bufsize will be supplied as the corresponding argument to the *open()* function when creating the stdin/stdout/stderr pipe file objects:

- `0` means unbuffered (read and write are one system call and can return short)
- `1` means line buffered (only usable if `universal_newlines=True` i.e., in a text mode)
- any other positive value means use a buffer of approximately that size
- negative bufsize (the default) means the system default of io.DEFAULT_BUFFER_SIZE will be used.

Changed in version 3.3.1: *bufsize* now defaults to -1 to enable buffering by default to match the behavior that most code expects. In versions prior to Python 3.2.4 and 3.3.1 it incorrectly defaulted to `0` which was unbuffered and allowed short reads. This was unintentional and did not match the behavior of Python 2 as most code expected.

The *executable* argument specifies a replacement program to execute. It is very seldom needed. When `shell=False`, *executable* replaces the program to execute specified by *args*. However, the original *args* is still passed to the program. Most programs treat the program specified by *args* as the command name, which can then be different from the program actually executed. On POSIX, the *args* name becomes the display name for the executable in utilities such as `ps`. If `shell=True`, on POSIX the *executable* argument specifies a replacement shell for the default `/bin/sh`.

stdin, *stdout* and *stderr* specify the executed program's standard input, standard output and standard error file handles, respectively. Valid values are *PIPE*, *DEVNULL*, an existing file descriptor (a positive integer), an existing *file object*, and `None`. *PIPE* indicates that a new pipe to the child should be created. *DEVNULL* indicates that the special file *os.devnull* will be used. With the default settings of `None`, no redirection will occur; the child's file handles will be inherited from the parent. Additionally, *stderr* can be *STDOUT*, which indicates that the stderr data from the applications should be captured into the same file handle as for stdout.

If *preexec_fn* is set to a callable object, this object will be called in the child process just before the child is executed. (POSIX only)

Warning: The *preexec_fn* parameter is not safe to use in the presence of threads in your application. The child process could deadlock before exec is called. If you must use it, keep it trivial! Minimize the number of libraries you call into.

Note: If you need to modify the environment for the child use the *env* parameter rather than doing

it in a *preexec_fn*. The *start_new_session* parameter can take the place of a previously common use of *preexec_fn* to call os.setsid() in the child.

If *close_fds* is true, all file descriptors except `0`, `1` and `2` will be closed before the child process is executed. Otherwise when *close_fds* is false, file descriptors obey their inheritable flag as described in *Inheritance of File Descriptors*.

On Windows, if *close_fds* is true then no handles will be inherited by the child process unless explicitly passed in the `handle_list` element of *STARTUPINFO.lpAttributeList*, or by standard handle redirection.

Changed in version 3.2: The default for *close_fds* was changed from *False* to what is described above.

Changed in version 3.7: On Windows the default for *close_fds* was changed from *False* to *True* when redirecting the standard handles. It's now possible to set *close_fds* to *True* when redirecting the standard handles.

pass_fds is an optional sequence of file descriptors to keep open between the parent and child. Providing any *pass_fds* forces *close_fds* to be *True*. (POSIX only)

New in version 3.2: The *pass_fds* parameter was added.

If *cwd* is not `None`, the function changes the working directory to *cwd* before executing the child. *cwd* can be a *str* and *path-like* object. In particular, the function looks for *executable* (or for the first item in *args*) relative to *cwd* if the executable path is a relative path.

Changed in version 3.6: *cwd* parameter accepts a *path-like object*.

If *restore_signals* is true (the default) all signals that Python has set to SIG_IGN are restored to SIG_DFL in the child process before the exec. Currently this includes the SIGPIPE, SIGXFZ and SIGXFSZ signals. (POSIX only)

Changed in version 3.2: *restore_signals* was added.

If *start_new_session* is true the setsid() system call will be made in the child process prior to the execution of the subprocess. (POSIX only)

Changed in version 3.2: *start_new_session* was added.

If *env* is not `None`, it must be a mapping that defines the environment variables for the new process; these are used instead of the default behavior of inheriting the current process' environment.

Note: If specified, *env* must provide any variables required for the program to execute. On Windows, in order to run a side-by-side assembly the specified *env* **must** include a valid `SystemRoot`.

If *encoding* or *errors* are specified, or *text* is true, the file objects *stdin*, *stdout* and *stderr* are opened in text mode with the specified encoding and *errors*, as described above in *Frequently Used Arguments*. The *universal_newlines* argument is equivalent to *text* and is provided for backwards compatibility. By default, file objects are opened in binary mode.

New in version 3.6: *encoding* and *errors* were added.

New in version 3.7: *text* was added as a more readable alias for *universal_newlines*.

If given, *startupinfo* will be a *STARTUPINFO* object, which is passed to the underlying `CreateProcess` function. *creationflags*, if given, can be one or more of the following flags:

- *CREATE_NEW_CONSOLE*
- *CREATE_NEW_PROCESS_GROUP*
- *ABOVE_NORMAL_PRIORITY_CLASS*
- *BELOW_NORMAL_PRIORITY_CLASS*

- *HIGH_PRIORITY_CLASS*
- *IDLE_PRIORITY_CLASS*
- *NORMAL_PRIORITY_CLASS*
- *REALTIME_PRIORITY_CLASS*
- *CREATE_NO_WINDOW*
- *DETACHED_PROCESS*
- *CREATE_DEFAULT_ERROR_MODE*
- *CREATE_BREAKAWAY_FROM_JOB*

Popen objects are supported as context managers via the `with` statement: on exit, standard file descriptors are closed, and the process is waited for.

```
with Popen(["ifconfig"], stdout=PIPE) as proc:
    log.write(proc.stdout.read())
```

Changed in version 3.2: Added context manager support.

Changed in version 3.6: Popen destructor now emits a *ResourceWarning* warning if the child process is still running.

Exceptions

Exceptions raised in the child process, before the new program has started to execute, will be re-raised in the parent. Additionally, the exception object will have one extra attribute called `child_traceback`, which is a string containing traceback information from the child's point of view.

The most common exception raised is *OSError*. This occurs, for example, when trying to execute a non-existent file. Applications should prepare for *OSError* exceptions.

A *ValueError* will be raised if *Popen* is called with invalid arguments.

check_call() and *check_output()* will raise *CalledProcessError* if the called process returns a non-zero return code.

All of the functions and methods that accept a *timeout* parameter, such as *call()* and *Popen.communicate()* will raise *TimeoutExpired* if the timeout expires before the process exits.

Exceptions defined in this module all inherit from *SubprocessError*.

New in version 3.3: The *SubprocessError* base class was added.

17.5.2 Security Considerations

Unlike some other popen functions, this implementation will never implicitly call a system shell. This means that all characters, including shell metacharacters, can safely be passed to child processes. If the shell is invoked explicitly, via `shell=True`, it is the application's responsibility to ensure that all whitespace and metacharacters are quoted appropriately to avoid shell injection vulnerabilities.

When using `shell=True`, the *shlex.quote()* function can be used to properly escape whitespace and shell metacharacters in strings that are going to be used to construct shell commands.

17.5.3 Popen Objects

Instances of the *Popen* class have the following methods:

`Popen.poll()`
Check if child process has terminated. Set and return *returncode* attribute. Otherwise, returns `None`.

`Popen.wait(`*timeout=None*`)`
Wait for child process to terminate. Set and return *returncode* attribute.

If the process does not terminate after *timeout* seconds, raise a *TimeoutExpired* exception. It is safe to catch this exception and retry the wait.

Note: This will deadlock when using `stdout=PIPE` or `stderr=PIPE` and the child process generates enough output to a pipe such that it blocks waiting for the OS pipe buffer to accept more data. Use *Popen.communicate()* when using pipes to avoid that.

Note: The function is implemented using a busy loop (non-blocking call and short sleeps). Use the *asyncio* module for an asynchronous wait: see *asyncio.create_subprocess_exec*.

Changed in version 3.3: *timeout* was added.

`Popen.communicate(`*input=None*, *timeout=None*`)`
Interact with process: Send data to stdin. Read data from stdout and stderr, until end-of-file is reached. Wait for process to terminate. The optional *input* argument should be data to be sent to the child process, or `None`, if no data should be sent to the child. If streams were opened in text mode, *input* must be a string. Otherwise, it must be bytes.

communicate() returns a tuple `(stdout_data, stderr_data)`. The data will be strings if streams were opened in text mode; otherwise, bytes.

Note that if you want to send data to the process's stdin, you need to create the Popen object with `stdin=PIPE`. Similarly, to get anything other than `None` in the result tuple, you need to give `stdout=PIPE` and/or `stderr=PIPE` too.

If the process does not terminate after *timeout* seconds, a *TimeoutExpired* exception will be raised. Catching this exception and retrying communication will not lose any output.

The child process is not killed if the timeout expires, so in order to cleanup properly a well-behaved application should kill the child process and finish communication:

```
proc = subprocess.Popen(...)
try:
    outs, errs = proc.communicate(timeout=15)
except TimeoutExpired:
    proc.kill()
    outs, errs = proc.communicate()
```

Note: The data read is buffered in memory, so do not use this method if the data size is large or unlimited.

Changed in version 3.3: *timeout* was added.

`Popen.send_signal(`*signal*`)`
Sends the signal *signal* to the child.

Note: On Windows, SIGTERM is an alias for *terminate()*. CTRL_C_EVENT and CTRL_BREAK_EVENT can be sent to processes started with a *creationflags* parameter which includes *CREATE_NEW_PROCESS_GROUP*.

`Popen.terminate()`
Stop the child. On Posix OSs the method sends SIGTERM to the child. On Windows the Win32 API function `TerminateProcess()` is called to stop the child.

`Popen.kill()`
Kills the child. On Posix OSs the function sends SIGKILL to the child. On Windows *kill()* is an alias for *terminate()*.

The following attributes are also available:

`Popen.args`
The *args* argument as it was passed to *Popen* – a sequence of program arguments or else a single string.

New in version 3.3.

`Popen.stdin`
If the *stdin* argument was *PIPE*, this attribute is a writeable stream object as returned by *open()*. If the *encoding* or *errors* arguments were specified or the *universal_newlines* argument was `True`, the stream is a text stream, otherwise it is a byte stream. If the *stdin* argument was not *PIPE*, this attribute is `None`.

`Popen.stdout`
If the *stdout* argument was *PIPE*, this attribute is a readable stream object as returned by *open()*. Reading from the stream provides output from the child process. If the *encoding* or *errors* arguments were specified or the *universal_newlines* argument was `True`, the stream is a text stream, otherwise it is a byte stream. If the *stdout* argument was not *PIPE*, this attribute is `None`.

`Popen.stderr`
If the *stderr* argument was *PIPE*, this attribute is a readable stream object as returned by *open()*. Reading from the stream provides error output from the child process. If the *encoding* or *errors* arguments were specified or the *universal_newlines* argument was `True`, the stream is a text stream, otherwise it is a byte stream. If the *stderr* argument was not *PIPE*, this attribute is `None`.

Warning: Use *communicate()* rather than *.stdin.write*, *.stdout.read* or *.stderr.read* to avoid deadlocks due to any of the other OS pipe buffers filling up and blocking the child process.

`Popen.pid`
The process ID of the child process.

Note that if you set the *shell* argument to `True`, this is the process ID of the spawned shell.

`Popen.returncode`
The child return code, set by *poll()* and *wait()* (and indirectly by *communicate()*). A `None` value indicates that the process hasn't terminated yet.

A negative value `-N` indicates that the child was terminated by signal `N` (POSIX only).

17.5.4 Windows Popen Helpers

The *STARTUPINFO* class and following constants are only available on Windows.

class subprocess.STARTUPINFO(*, *dwFlags=0*, *hStdInput=None*, *hStdOutput=None*, *hStdError=None*, *wShowWindow=0*, *lpAttributeList=None*)

Partial support of the Windows STARTUPINFO structure is used for *Popen* creation. The following attributes can be set by passing them as keyword-only arguments.

Changed in version 3.7: Keyword-only argument support was added.

dwFlags

A bit field that determines whether certain *STARTUPINFO* attributes are used when the process creates a window.

```
si = subprocess.STARTUPINFO()
si.dwFlags = subprocess.STARTF_USESTDHANDLES | subprocess.STARTF_USESHOWWINDOW
```

hStdInput

If *dwFlags* specifies *STARTF_USESTDHANDLES*, this attribute is the standard input handle for the process. If *STARTF_USESTDHANDLES* is not specified, the default for standard input is the keyboard buffer.

hStdOutput

If *dwFlags* specifies *STARTF_USESTDHANDLES*, this attribute is the standard output handle for the process. Otherwise, this attribute is ignored and the default for standard output is the console window's buffer.

hStdError

If *dwFlags* specifies *STARTF_USESTDHANDLES*, this attribute is the standard error handle for the process. Otherwise, this attribute is ignored and the default for standard error is the console window's buffer.

wShowWindow

If *dwFlags* specifies *STARTF_USESHOWWINDOW*, this attribute can be any of the values that can be specified in the `nCmdShow` parameter for the ShowWindow function, except for `SW_SHOWDEFAULT`. Otherwise, this attribute is ignored.

SW_HIDE is provided for this attribute. It is used when *Popen* is called with `shell=True`.

lpAttributeList

A dictionary of additional attributes for process creation as given in `STARTUPINFOEX`, see UpdateProcThreadAttribute.

Supported attributes:

handle_list Sequence of handles that will be inherited. *close_fds* must be true if non-empty.

The handles must be temporarily made inheritable by *os.set_handle_inheritable()* when passed to the *Popen* constructor, else *OSError* will be raised with Windows error `ERROR_INVALID_PARAMETER` (87).

> **Warning:** In a multithreaded process, use caution to avoid leaking handles that are marked inheritable when combining this feature with concurrent calls to other process creation functions that inherit all handles such as *os.system()*. This also applies to standard handle redirection, which temporarily creates inheritable handles.

New in version 3.7.

Windows Constants

The *subprocess* module exposes the following constants.

subprocess.STD_INPUT_HANDLE
The standard input device. Initially, this is the console input buffer, CONIN$.

subprocess.STD_OUTPUT_HANDLE
The standard output device. Initially, this is the active console screen buffer, CONOUT$.

subprocess.STD_ERROR_HANDLE
The standard error device. Initially, this is the active console screen buffer, CONOUT$.

subprocess.SW_HIDE
Hides the window. Another window will be activated.

subprocess.STARTF_USESTDHANDLES
Specifies that the *STARTUPINFO.hStdInput*, *STARTUPINFO.hStdOutput*, and *STARTUPINFO.hStdError* attributes contain additional information.

subprocess.STARTF_USESHOWWINDOW
Specifies that the *STARTUPINFO.wShowWindow* attribute contains additional information.

subprocess.CREATE_NEW_CONSOLE
The new process has a new console, instead of inheriting its parent's console (the default).

subprocess.CREATE_NEW_PROCESS_GROUP
A *Popen* `creationflags` parameter to specify that a new process group will be created. This flag is necessary for using *os.kill()* on the subprocess.

This flag is ignored if *CREATE_NEW_CONSOLE* is specified.

subprocess.ABOVE_NORMAL_PRIORITY_CLASS
A *Popen* `creationflags` parameter to specify that a new process will have an above average priority.

New in version 3.7.

subprocess.BELOW_NORMAL_PRIORITY_CLASS
A *Popen* `creationflags` parameter to specify that a new process will have a below average priority.

New in version 3.7.

subprocess.HIGH_PRIORITY_CLASS
A *Popen* `creationflags` parameter to specify that a new process will have a high priority.

New in version 3.7.

subprocess.IDLE_PRIORITY_CLASS
A *Popen* `creationflags` parameter to specify that a new process will have an idle (lowest) priority.

New in version 3.7.

subprocess.NORMAL_PRIORITY_CLASS
A *Popen* `creationflags` parameter to specify that a new process will have an normal priority. (default)

New in version 3.7.

subprocess.REALTIME_PRIORITY_CLASS
A *Popen* `creationflags` parameter to specify that a new process will have realtime priority. You should almost never use REALTIME_PRIORITY_CLASS, because this interrupts system threads that manage mouse input, keyboard input, and background disk flushing. This class can be appropriate for applications that "talk" directly to hardware or that perform brief tasks that should have limited interruptions.

New in version 3.7.

subprocess.CREATE_NO_WINDOW
A *Popen* `creationflags` parameter to specify that a new process will not create a window

New in version 3.7.

subprocess.DETACHED_PROCESS
A *Popen* creationflags parameter to specify that a new process will not inherit its parent's console. This value cannot be used with CREATE_NEW_CONSOLE.

New in version 3.7.

subprocess.CREATE_DEFAULT_ERROR_MODE
A *Popen* creationflags parameter to specify that a new process does not inherit the error mode of the calling process. Instead, the new process gets the default error mode. This feature is particularly useful for multithreaded shell applications that run with hard errors disabled.

New in version 3.7.

subprocess.CREATE_BREAKAWAY_FROM_JOB
A *Popen* creationflags parameter to specify that a new process is not associated with the job.

New in version 3.7.

17.5.5 Older high-level API

Prior to Python 3.5, these three functions comprised the high level API to subprocess. You can now use *run()* in many cases, but lots of existing code calls these functions.

subprocess.call(*args*, ***, *stdin=None*, *stdout=None*, *stderr=None*, *shell=False*, *cwd=None*, *timeout=None*)
Run the command described by *args*. Wait for command to complete, then return the *returncode* attribute.

This is equivalent to:

```
run(...).returncode
```

(except that the *input* and *check* parameters are not supported)

The arguments shown above are merely the most common ones. The full function signature is largely the same as that of the *Popen* constructor - this function passes all supplied arguments other than *timeout* directly through to that interface.

Note: Do not use stdout=PIPE or stderr=PIPE with this function. The child process will block if it generates enough output to a pipe to fill up the OS pipe buffer as the pipes are not being read from.

Changed in version 3.3: *timeout* was added.

subprocess.check_call(*args*, ***, *stdin=None*, *stdout=None*, *stderr=None*, *shell=False*, *cwd=None*, *timeout=None*)
Run command with arguments. Wait for command to complete. If the return code was zero then return, otherwise raise *CalledProcessError*. The *CalledProcessError* object will have the return code in the *returncode* attribute.

This is equivalent to:

```
run(..., check=True)
```

(except that the *input* parameter is not supported)

The arguments shown above are merely the most common ones. The full function signature is largely the same as that of the *Popen* constructor - this function passes all supplied arguments other than *timeout* directly through to that interface.

Note: Do not use `stdout=PIPE` or `stderr=PIPE` with this function. The child process will block if it generates enough output to a pipe to fill up the OS pipe buffer as the pipes are not being read from.

Changed in version 3.3: *timeout* was added.

subprocess.check_output(*args*, ***, *stdin=None*, *stderr=None*, *shell=False*, *cwd=None*, *encoding=None*, *errors=None*, *universal_newlines=False*, *timeout=None*)

Run command with arguments and return its output.

If the return code was non-zero it raises a *CalledProcessError*. The *CalledProcessError* object will have the return code in the *returncode* attribute and any output in the *output* attribute.

This is equivalent to:

```
run(..., check=True, stdout=PIPE).stdout
```

The arguments shown above are merely the most common ones. The full function signature is largely the same as that of *run()* - most arguments are passed directly through to that interface. However, explicitly passing `input=None` to inherit the parent's standard input file handle is not supported.

By default, this function will return the data as encoded bytes. The actual encoding of the output data may depend on the command being invoked, so the decoding to text will often need to be handled at the application level.

This behaviour may be overridden by setting *universal_newlines* to `True` as described above in *Frequently Used Arguments*.

To also capture standard error in the result, use `stderr=subprocess.STDOUT`:

```
>>> subprocess.check_output(
...     "ls non_existent_file; exit 0",
...     stderr=subprocess.STDOUT,
...     shell=True)
'ls: non_existent_file: No such file or directory\n'
```

New in version 3.1.

Changed in version 3.3: *timeout* was added.

Changed in version 3.4: Support for the *input* keyword argument was added.

Changed in version 3.6: *encoding* and *errors* were added. See *run()* for details.

17.5.6 Replacing Older Functions with the subprocess Module

In this section, "a becomes b" means that b can be used as a replacement for a.

Note: All "a" functions in this section fail (more or less) silently if the executed program cannot be found; the "b" replacements raise *OSError* instead.

In addition, the replacements using *check_output()* will fail with a *CalledProcessError* if the requested operation produces a non-zero return code. The output is still available as the *output* attribute of the raised exception.

In the following examples, we assume that the relevant functions have already been imported from the *subprocess* module.

Replacing /bin/sh shell backquote

```
output=`mycmd myarg`
```

becomes:

```
output = check_output(["mycmd", "myarg"])
```

Replacing shell pipeline

```
output=`dmesg | grep hda`
```

becomes:

```
p1 = Popen(["dmesg"], stdout=PIPE)
p2 = Popen(["grep", "hda"], stdin=p1.stdout, stdout=PIPE)
p1.stdout.close()  # Allow p1 to receive a SIGPIPE if p2 exits.
output = p2.communicate()[0]
```

The p1.stdout.close() call after starting the p2 is important in order for p1 to receive a SIGPIPE if p2 exits before p1.

Alternatively, for trusted input, the shell's own pipeline support may still be used directly:

```
output=`dmesg | grep hda`
```

becomes:

```
output=check_output("dmesg | grep hda", shell=True)
```

Replacing `os.system()`

```
sts = os.system("mycmd" + " myarg")
# becomes
sts = call("mycmd" + " myarg", shell=True)
```

Notes:

- Calling the program through the shell is usually not required.

A more realistic example would look like this:

```
try:
    retcode = call("mycmd" + " myarg", shell=True)
    if retcode < 0:
        print("Child was terminated by signal", -retcode, file=sys.stderr)
    else:
        print("Child returned", retcode, file=sys.stderr)
except OSError as e:
    print("Execution failed:", e, file=sys.stderr)
```

Replacing the `os.spawn` family

P_NOWAIT example:

```
pid = os.spawnlp(os.P_NOWAIT, "/bin/mycmd", "mycmd", "myarg")
==>
pid = Popen(["/bin/mycmd", "myarg"]).pid
```

P_WAIT example:

```
retcode = os.spawnlp(os.P_WAIT, "/bin/mycmd", "mycmd", "myarg")
==>
retcode = call(["/bin/mycmd", "myarg"])
```

Vector example:

```
os.spawnvp(os.P_NOWAIT, path, args)
==>
Popen([path] + args[1:])
```

Environment example:

```
os.spawnlpe(os.P_NOWAIT, "/bin/mycmd", "mycmd", "myarg", env)
==>
Popen(["/bin/mycmd", "myarg"], env={"PATH": "/usr/bin"})
```

Replacing `os.popen()`, `os.popen2()`, `os.popen3()`

```
(child_stdin, child_stdout) = os.popen2(cmd, mode, bufsize)
==>
p = Popen(cmd, shell=True, bufsize=bufsize,
          stdin=PIPE, stdout=PIPE, close_fds=True)
(child_stdin, child_stdout) = (p.stdin, p.stdout)
```

```
(child_stdin,
 child_stdout,
 child_stderr) = os.popen3(cmd, mode, bufsize)
==>
p = Popen(cmd, shell=True, bufsize=bufsize,
          stdin=PIPE, stdout=PIPE, stderr=PIPE, close_fds=True)
(child_stdin,
 child_stdout,
 child_stderr) = (p.stdin, p.stdout, p.stderr)
```

```
(child_stdin, child_stdout_and_stderr) = os.popen4(cmd, mode, bufsize)
==>
p = Popen(cmd, shell=True, bufsize=bufsize,
          stdin=PIPE, stdout=PIPE, stderr=STDOUT, close_fds=True)
(child_stdin, child_stdout_and_stderr) = (p.stdin, p.stdout)
```

Return code handling translates as follows:

```
pipe = os.popen(cmd, 'w')
...
rc = pipe.close()
if rc is not None and rc >> 8:
    print("There were some errors")
==>
process = Popen(cmd, stdin=PIPE)
```

(continues on next page)

(continued from previous page)

```
...
process.stdin.close()
if process.wait() != 0:
    print("There were some errors")
```

Replacing functions from the popen2 module

Note: If the cmd argument to popen2 functions is a string, the command is executed through /bin/sh. If it is a list, the command is directly executed.

```
(child_stdout, child_stdin) = popen2.popen2("somestring", bufsize, mode)
==>
p = Popen("somestring", shell=True, bufsize=bufsize,
          stdin=PIPE, stdout=PIPE, close_fds=True)
(child_stdout, child_stdin) = (p.stdout, p.stdin)
```

```
(child_stdout, child_stdin) = popen2.popen2(["mycmd", "myarg"], bufsize, mode)
==>
p = Popen(["mycmd", "myarg"], bufsize=bufsize,
          stdin=PIPE, stdout=PIPE, close_fds=True)
(child_stdout, child_stdin) = (p.stdout, p.stdin)
```

popen2.Popen3 and popen2.Popen4 basically work as *subprocess.Popen*, except that:

- *Popen* raises an exception if the execution fails.
- the *capturestderr* argument is replaced with the *stderr* argument.
- stdin=PIPE and stdout=PIPE must be specified.
- popen2 closes all file descriptors by default, but you have to specify close_fds=True with *Popen* to guarantee this behavior on all platforms or past Python versions.

17.5.7 Legacy Shell Invocation Functions

This module also provides the following legacy functions from the 2.x commands module. These operations implicitly invoke the system shell and none of the guarantees described above regarding security and exception handling consistency are valid for these functions.

subprocess.getstatusoutput(*cmd*)

Return (exitcode, output) of executing *cmd* in a shell.

Execute the string *cmd* in a shell with Popen.check_output() and return a 2-tuple (exitcode, output). The locale encoding is used; see the notes on *Frequently Used Arguments* for more details.

A trailing newline is stripped from the output. The exit code for the command can be interpreted as the return code of subprocess. Example:

```
>>> subprocess.getstatusoutput('ls /bin/ls')
(0, '/bin/ls')
>>> subprocess.getstatusoutput('cat /bin/junk')
(1, 'cat: /bin/junk: No such file or directory')
>>> subprocess.getstatusoutput('/bin/junk')
(127, 'sh: /bin/junk: not found')
```

(continues on next page)

(continued from previous page)

```
>>> subprocess.getstatusoutput('/bin/kill $$')
(-15, '')
```

Availability: POSIX & Windows

Changed in version 3.3.4: Windows support was added.

The function now returns (exitcode, output) instead of (status, output) as it did in Python 3.3.3 and earlier. See `WEXITSTATUS()`.

`subprocess.getoutput(`*cmd*`)`
Return output (stdout and stderr) of executing *cmd* in a shell.

Like *`getstatusoutput()`*, except the exit status is ignored and the return value is a string containing the command's output. Example:

```
>>> subprocess.getoutput('ls /bin/ls')
'/bin/ls'
```

Availability: POSIX & Windows

Changed in version 3.3.4: Windows support added

17.5.8 Notes

Converting an argument sequence to a string on Windows

On Windows, an *args* sequence is converted to a string that can be parsed using the following rules (which correspond to the rules used by the MS C runtime):

1. Arguments are delimited by white space, which is either a space or a tab.
2. A string surrounded by double quotation marks is interpreted as a single argument, regardless of white space contained within. A quoted string can be embedded in an argument.
3. A double quotation mark preceded by a backslash is interpreted as a literal double quotation mark.
4. Backslashes are interpreted literally, unless they immediately precede a double quotation mark.
5. If backslashes immediately precede a double quotation mark, every pair of backslashes is interpreted as a literal backslash. If the number of backslashes is odd, the last backslash escapes the next double quotation mark as described in rule 3.

See also:

`shlex` Module which provides function to parse and escape command lines.

17.6 `sched` — Event scheduler

Source code: Lib/sched.py

The *`sched`* module defines a class which implements a general purpose event scheduler:

`class sched.scheduler(`*timefunc=time.monotonic*, *delayfunc=time.sleep*`)`
The *`scheduler`* class defines a generic interface to scheduling events. It needs two functions to actually deal with the "outside world" — *timefunc* should be callable without arguments, and return a number (the "time", in any units whatsoever). If time.monotonic is not available, the *timefunc* default is

time.time instead. The *delayfunc* function should be callable with one argument, compatible with the output of *timefunc*, and should delay that many time units. *delayfunc* will also be called with the argument `0` after each event is run to allow other threads an opportunity to run in multi-threaded applications.

Changed in version 3.3: *timefunc* and *delayfunc* parameters are optional.

Changed in version 3.3: *scheduler* class can be safely used in multi-threaded environments.

Example:

```
>>> import sched, time
>>> s = sched.scheduler(time.time, time.sleep)
>>> def print_time(a='default'):
...     print("From print_time", time.time(), a)
...
>>> def print_some_times():
...     print(time.time())
...     s.enter(10, 1, print_time)
...     s.enter(5, 2, print_time, argument=('positional',))
...     s.enter(5, 1, print_time, kwargs={'a': 'keyword'})
...     s.run()
...     print(time.time())
...
>>> print_some_times()
930343690.257
From print_time 930343695.274 positional
From print_time 930343695.275 keyword
From print_time 930343700.273 default
930343700.276
```

17.6.1 Scheduler Objects

scheduler instances have the following methods and attributes:

scheduler.enterabs(*time*, *priority*, *action*, *argument=()*, *kwargs={}*)

Schedule a new event. The *time* argument should be a numeric type compatible with the return value of the *timefunc* function passed to the constructor. Events scheduled for the same *time* will be executed in the order of their *priority*. A lower number represents a higher priority.

Executing the event means executing `action(*argument, **kwargs)`. *argument* is a sequence holding the positional arguments for *action*. *kwargs* is a dictionary holding the keyword arguments for *action*.

Return value is an event which may be used for later cancellation of the event (see *cancel()*).

Changed in version 3.3: *argument* parameter is optional.

New in version 3.3: *kwargs* parameter was added.

scheduler.enter(*delay*, *priority*, *action*, *argument=()*, *kwargs={}*)

Schedule an event for *delay* more time units. Other than the relative time, the other arguments, the effect and the return value are the same as those for *enterabs()*.

Changed in version 3.3: *argument* parameter is optional.

New in version 3.3: *kwargs* parameter was added.

scheduler.cancel(*event*)

Remove the event from the queue. If *event* is not an event currently in the queue, this method will raise a *ValueError*.

`scheduler.empty()`
Return true if the event queue is empty.

`scheduler.run(`*blocking=True*`)`
Run all scheduled events. This method will wait (using the `delayfunc()` function passed to the constructor) for the next event, then execute it and so on until there are no more scheduled events.

If *blocking* is false executes the scheduled events due to expire soonest (if any) and then return the deadline of the next scheduled call in the scheduler (if any).

Either *action* or *delayfunc* can raise an exception. In either case, the scheduler will maintain a consistent state and propagate the exception. If an exception is raised by *action*, the event will not be attempted in future calls to *run()*.

If a sequence of events takes longer to run than the time available before the next event, the scheduler will simply fall behind. No events will be dropped; the calling code is responsible for canceling events which are no longer pertinent.

New in version 3.3: *blocking* parameter was added.

`scheduler.queue`
Read-only attribute returning a list of upcoming events in the order they will be run. Each event is shown as a *named tuple* with the following fields: time, priority, action, argument, kwargs.

17.7 queue — A synchronized queue class

Source code: Lib/queue.py

The *queue* module implements multi-producer, multi-consumer queues. It is especially useful in threaded programming when information must be exchanged safely between multiple threads. The *Queue* class in this module implements all the required locking semantics. It depends on the availability of thread support in Python; see the *threading* module.

The module implements three types of queue, which differ only in the order in which the entries are retrieved. In a FIFO queue, the first tasks added are the first retrieved. In a LIFO queue, the most recently added entry is the first retrieved (operating like a stack). With a priority queue, the entries are kept sorted (using the *heapq* module) and the lowest valued entry is retrieved first.

Internally, those three types of queues use locks to temporarily block competing threads; however, they are not designed to handle reentrancy within a thread.

In addition, the module implements a "simple" FIFO queue type where specific implementations can provide additional guarantees in exchange for the smaller functionality.

The *queue* module defines the following classes and exceptions:

`class queue.Queue(`*maxsize=0*`)`
Constructor for a FIFO queue. *maxsize* is an integer that sets the upperbound limit on the number of items that can be placed in the queue. Insertion will block once this size has been reached, until queue items are consumed. If *maxsize* is less than or equal to zero, the queue size is infinite.

`class queue.LifoQueue(`*maxsize=0*`)`
Constructor for a LIFO queue. *maxsize* is an integer that sets the upperbound limit on the number of items that can be placed in the queue. Insertion will block once this size has been reached, until queue items are consumed. If *maxsize* is less than or equal to zero, the queue size is infinite.

`class queue.PriorityQueue(`*maxsize=0*`)`
Constructor for a priority queue. *maxsize* is an integer that sets the upperbound limit on the number

of items that can be placed in the queue. Insertion will block once this size has been reached, until queue items are consumed. If *maxsize* is less than or equal to zero, the queue size is infinite.

The lowest valued entries are retrieved first (the lowest valued entry is the one returned by `sorted(list(entries))[0]`). A typical pattern for entries is a tuple in the form: `(priority_number, data)`.

If the *data* elements are not comparable, the data can be wrapped in a class that ignores the data item and only compares the priority number:

```
from dataclasses import dataclass, field
from typing import Any

@dataclass(order=True)
class PrioritizedItem:
    priority: int
    item: Any=field(compare=False)
```

class queue.SimpleQueue
Constructor for an unbounded FIFO queue. Simple queues lack advanced functionality such as task tracking.

New in version 3.7.

exception queue.Empty
Exception raised when non-blocking *get()* (or *get_nowait()*) is called on a *Queue* object which is empty.

exception queue.Full
Exception raised when non-blocking *put()* (or *put_nowait()*) is called on a *Queue* object which is full.

17.7.1 Queue Objects

Queue objects (*Queue*, *LifoQueue*, or *PriorityQueue*) provide the public methods described below.

Queue.qsize()
Return the approximate size of the queue. Note, qsize() > 0 doesn't guarantee that a subsequent get() will not block, nor will qsize() < maxsize guarantee that put() will not block.

Queue.empty()
Return `True` if the queue is empty, `False` otherwise. If empty() returns `True` it doesn't guarantee that a subsequent call to put() will not block. Similarly, if empty() returns `False` it doesn't guarantee that a subsequent call to get() will not block.

Queue.full()
Return `True` if the queue is full, `False` otherwise. If full() returns `True` it doesn't guarantee that a subsequent call to get() will not block. Similarly, if full() returns `False` it doesn't guarantee that a subsequent call to put() will not block.

Queue.put(*item*, *block=True*, *timeout=None*)
Put *item* into the queue. If optional args *block* is true and *timeout* is `None` (the default), block if necessary until a free slot is available. If *timeout* is a positive number, it blocks at most *timeout* seconds and raises the *Full* exception if no free slot was available within that time. Otherwise (*block* is false), put an item on the queue if a free slot is immediately available, else raise the *Full* exception (*timeout* is ignored in that case).

Queue.put_nowait(*item*)
Equivalent to `put(item, False)`.

`Queue.get`(*block=True*, *timeout=None*)
Remove and return an item from the queue. If optional args *block* is true and *timeout* is `None` (the default), block if necessary until an item is available. If *timeout* is a positive number, it blocks at most *timeout* seconds and raises the *Empty* exception if no item was available within that time. Otherwise (*block* is false), return an item if one is immediately available, else raise the *Empty* exception (*timeout* is ignored in that case).

`Queue.get_nowait()`
Equivalent to `get(False)`.

Two methods are offered to support tracking whether enqueued tasks have been fully processed by daemon consumer threads.

`Queue.task_done()`
Indicate that a formerly enqueued task is complete. Used by queue consumer threads. For each *get()* used to fetch a task, a subsequent call to *task_done()* tells the queue that the processing on the task is complete.

If a *join()* is currently blocking, it will resume when all items have been processed (meaning that a *task_done()* call was received for every item that had been *put()* into the queue).

Raises a *ValueError* if called more times than there were items placed in the queue.

`Queue.join()`
Blocks until all items in the queue have been gotten and processed.

The count of unfinished tasks goes up whenever an item is added to the queue. The count goes down whenever a consumer thread calls *task_done()* to indicate that the item was retrieved and all work on it is complete. When the count of unfinished tasks drops to zero, *join()* unblocks.

Example of how to wait for enqueued tasks to be completed:

```
def worker():
    while True:
        item = q.get()
        if item is None:
            break
        do_work(item)
        q.task_done()

q = queue.Queue()
threads = []
for i in range(num_worker_threads):
    t = threading.Thread(target=worker)
    t.start()
    threads.append(t)

for item in source():
    q.put(item)

# block until all tasks are done
q.join()

# stop workers
for i in range(num_worker_threads):
    q.put(None)
for t in threads:
    t.join()
```

17.7.2 SimpleQueue Objects

SimpleQueue objects provide the public methods described below.

`SimpleQueue.qsize()`
Return the approximate size of the queue. Note, qsize() > 0 doesn't guarantee that a subsequent get() will not block.

`SimpleQueue.empty()`
Return `True` if the queue is empty, `False` otherwise. If empty() returns `False` it doesn't guarantee that a subsequent call to get() will not block.

`SimpleQueue.put(`*item*, *block=True*, *timeout=None*`)`
Put *item* into the queue. The method never blocks and always succeeds (except for potential low-level errors such as failure to allocate memory). The optional args *block* and *timeout* are ignored and only provided for compatibility with *Queue.put()*.

CPython implementation detail: This method has a C implementation which is reentrant. That is, a `put()` or `get()` call can be interrupted by another `put()` call in the same thread without deadlocking or corrupting internal state inside the queue. This makes it appropriate for use in destructors such as `__del__` methods or *weakref* callbacks.

`SimpleQueue.put_nowait(`*item*`)`
Equivalent to `put(item)`, provided for compatibility with *Queue.put_nowait()*.

`SimpleQueue.get(`*block=True*, *timeout=None*`)`
Remove and return an item from the queue. If optional args *block* is true and *timeout* is `None` (the default), block if necessary until an item is available. If *timeout* is a positive number, it blocks at most *timeout* seconds and raises the *Empty* exception if no item was available within that time. Otherwise (*block* is false), return an item if one is immediately available, else raise the *Empty* exception (*timeout* is ignored in that case).

`SimpleQueue.get_nowait()`
Equivalent to `get(False)`.

See also:

Class *multiprocessing.Queue* A queue class for use in a multi-processing (rather than multi-threading) context.

collections.deque is an alternative implementation of unbounded queues with fast atomic *append()* and *popleft()* operations that do not require locking.

The following are support modules for some of the above services:

17.8 _thread — Low-level threading API

This module provides low-level primitives for working with multiple threads (also called *light-weight processes* or *tasks*) — multiple threads of control sharing their global data space. For synchronization, simple locks (also called *mutexes* or *binary semaphores*) are provided. The *threading* module provides an easier to use and higher-level threading API built on top of this module.

Changed in version 3.7: This module used to be optional, it is now always available.

This module defines the following constants and functions:

`exception _thread.error`
Raised on thread-specific errors.

Changed in version 3.3: This is now a synonym of the built-in *RuntimeError*.

_thread.LockType
: This is the type of lock objects.

_thread.start_new_thread(*function*, *args*[, *kwargs*])
: Start a new thread and return its identifier. The thread executes the function *function* with the argument list *args* (which must be a tuple). The optional *kwargs* argument specifies a dictionary of keyword arguments. When the function returns, the thread silently exits. When the function terminates with an unhandled exception, a stack trace is printed and then the thread exits (but other threads continue to run).

_thread.interrupt_main()
: Raise a *KeyboardInterrupt* exception in the main thread. A subthread can use this function to interrupt the main thread.

_thread.exit()
: Raise the *SystemExit* exception. When not caught, this will cause the thread to exit silently.

_thread.allocate_lock()
: Return a new lock object. Methods of locks are described below. The lock is initially unlocked.

_thread.get_ident()
: Return the 'thread identifier' of the current thread. This is a nonzero integer. Its value has no direct meaning; it is intended as a magic cookie to be used e.g. to index a dictionary of thread-specific data. Thread identifiers may be recycled when a thread exits and another thread is created.

_thread.stack_size([*size*])
: Return the thread stack size used when creating new threads. The optional *size* argument specifies the stack size to be used for subsequently created threads, and must be 0 (use platform or configured default) or a positive integer value of at least 32,768 (32 KiB). If *size* is not specified, 0 is used. If changing the thread stack size is unsupported, a *RuntimeError* is raised. If the specified stack size is invalid, a *ValueError* is raised and the stack size is unmodified. 32 KiB is currently the minimum supported stack size value to guarantee sufficient stack space for the interpreter itself. Note that some platforms may have particular restrictions on values for the stack size, such as requiring a minimum stack size > 32 KiB or requiring allocation in multiples of the system memory page size - platform documentation should be referred to for more information (4 KiB pages are common; using multiples of 4096 for the stack size is the suggested approach in the absence of more specific information). Availability: Windows, systems with POSIX threads.

_thread.TIMEOUT_MAX
: The maximum value allowed for the *timeout* parameter of `Lock.acquire()`. Specifying a timeout greater than this value will raise an *OverflowError*.

  New in version 3.2.

Lock objects have the following methods:

lock.acquire(*waitflag=1*, *timeout=-1*)
: Without any optional argument, this method acquires the lock unconditionally, if necessary waiting until it is released by another thread (only one thread at a time can acquire a lock — that's their reason for existence).

  If the integer *waitflag* argument is present, the action depends on its value: if it is zero, the lock is only acquired if it can be acquired immediately without waiting, while if it is nonzero, the lock is acquired unconditionally as above.

  If the floating-point *timeout* argument is present and positive, it specifies the maximum wait time in seconds before returning. A negative *timeout* argument specifies an unbounded wait. You cannot specify a *timeout* if *waitflag* is zero.

  The return value is `True` if the lock is acquired successfully, `False` if not.

  Changed in version 3.2: The *timeout* parameter is new.

Changed in version 3.2: Lock acquires can now be interrupted by signals on POSIX.

`lock.release()`
Releases the lock. The lock must have been acquired earlier, but not necessarily by the same thread.

`lock.locked()`
Return the status of the lock: `True` if it has been acquired by some thread, `False` if not.

In addition to these methods, lock objects can also be used via the `with` statement, e.g.:

```
import _thread

a_lock = _thread.allocate_lock()

with a_lock:
    print("a_lock is locked while this executes")
```

Caveats:

- Threads interact strangely with interrupts: the *KeyboardInterrupt* exception will be received by an arbitrary thread. (When the *signal* module is available, interrupts always go to the main thread.)
- Calling *sys.exit()* or raising the *SystemExit* exception is equivalent to calling *_thread.exit()*.
- It is not possible to interrupt the `acquire()` method on a lock — the *KeyboardInterrupt* exception will happen after the lock has been acquired.
- When the main thread exits, it is system defined whether the other threads survive. On most systems, they are killed without executing `try` … `finally` clauses or executing object destructors.
- When the main thread exits, it does not do any of its usual cleanup (except that `try` … `finally` clauses are honored), and the standard I/O files are not flushed.

17.9 `_dummy_thread` — Drop-in replacement for the `_thread` module

Source code: Lib/_dummy_thread.py

Deprecated since version 3.7: Python now always has threading enabled. Please use *_thread* (or, better, *threading*) instead.

This module provides a duplicate interface to the *_thread* module. It was meant to be imported when the *_thread* module was not provided on a platform.

Be careful to not use this module where deadlock might occur from a thread being created that blocks waiting for another thread to be created. This often occurs with blocking I/O.

17.10 `dummy_threading` — Drop-in replacement for the `threading` module

Source code: Lib/dummy_threading.py

Deprecated since version 3.7: Python now always has threading enabled. Please use *threading* instead.

This module provides a duplicate interface to the *threading* module. It was meant to be imported when the *_thread* module was not provided on a platform.

Be careful to not use this module where deadlock might occur from a thread being created that blocks waiting for another thread to be created. This often occurs with blocking I/O.

CHAPTER

EIGHTEEN

CONTEXTVARS — CONTEXT VARIABLES

This module provides APIs to manage, store, and access context-local state. The *ContextVar* class is used to declare and work with *Context Variables*. The *copy_context()* function and the *Context* class should be used to manage the current context in asynchronous frameworks.

Context managers that have state should use Context Variables instead of *threading.local()* to prevent their state from bleeding to other code unexpectedly, when used in concurrent code.

See also **PEP 567** for additional details.

New in version 3.7.

18.1 Context Variables

class contextvars.**ContextVar**(*name*[, *, *default*])

This class is used to declare a new Context Variable, e.g.:

```
var: ContextVar[int] = ContextVar('var', default=42)
```

The required *name* parameter is used for introspection and debug purposes.

The optional keyword-only *default* parameter is returned by *ContextVar.get()* when no value for the variable is found in the current context.

Important: Context Variables should be created at the top module level and never in closures. *Context* objects hold strong references to context variables which prevents context variables from being properly garbage collected.

name

The name of the variable. This is a read-only property.

New in version 3.7.1.

get([*default*])

Return a value for the context variable for the current context.

If there is no value for the variable in the current context, the method will:

- return the value of the *default* argument of the method, if provided; or
- return the default value for the context variable, if it was created with one; or
- raise a *LookupError*.

set(*value*)
Call to set a new value for the context variable in the current context.

The required *value* argument is the new value for the context variable.

Returns a *Token* object that can be used to restore the variable to its previous value via the *ContextVar.reset()* method.

reset(*token*)
Reset the context variable to the value it had before the *ContextVar.set()* that created the *token* was used.

For example:

```
var = ContextVar('var')

token = var.set('new value')
# code that uses 'var'; var.get() returns 'new value'.
var.reset(token)

# After the reset call the var has no value again, so
# var.get() would raise a LookupError.
```

class contextvars.Token
Token objects are returned by the *ContextVar.set()* method. They can be passed to the *ContextVar.reset()* method to revert the value of the variable to what it was before the corresponding *set*.

Token.var
A read-only property. Points to the *ContextVar* object that created the token.

Token.old_value
A read-only property. Set to the value the variable had before the *ContextVar.set()* method call that created the token. It points to `Token.MISSING` is the variable was not set before the call.

Token.MISSING
A marker object used by `Token.old_value`.

18.2 Manual Context Management

contextvars.copy_context()
Returns a copy of the current *Context* object.

The following snippet gets a copy of the current context and prints all variables and their values that are set in it:

```
ctx: Context = copy_context()
print(list(ctx.items()))
```

The function has an O(1) complexity, i.e. works equally fast for contexts with a few context variables and for contexts that have a lot of them.

class contextvars.Context
A mapping of *ContextVars* to their values.

`Context()` creates an empty context with no values in it. To get a copy of the current context use the *copy_context()* function.

Context implements the *collections.abc.Mapping* interface.

run(*callable*, **args*, ***kwargs*)
Execute `callable(*args, **kwargs)` code in the context object the *run* method is called on. Return the result of the execution or propagate an exception if one occurred.

Any changes to any context variables that *callable* makes will be contained in the context object:

```
var = ContextVar('var')
var.set('spam')

def main():
    # 'var' was set to 'spam' before
    # calling 'copy_context()' and 'ctx.run(main)', so:
    # var.get() == ctx[var] == 'spam'

    var.set('ham')

    # Now, after setting 'var' to 'ham':
    # var.get() == ctx[var] == 'ham'

ctx = copy_context()

# Any changes that the 'main' function makes to 'var'
# will be contained in 'ctx'.
ctx.run(main)

# The 'main()' function was run in the 'ctx' context,
# so changes to 'var' are contained in it:
# ctx[var] == 'ham'

# However, outside of 'ctx', 'var' is still set to 'spam':
# var.get() == 'spam'
```

The method raises a *RuntimeError* when called on the same context object from more than one OS thread, or when called recursively.

copy()
Return a shallow copy of the context object.

var in context
Return `True` if the *context* has a value for *var* set; return `False` otherwise.

context[var]
Return the value of the *var* *ContextVar* variable. If the variable is not set in the context object, a *KeyError* is raised.

get(*var*[, *default*])
Return the value for *var* if *var* has the value in the context object. Return *default* otherwise. If *default* is not given, return `None`.

iter(context)
Return an iterator over the variables stored in the context object.

len(proxy)
Return the number of variables set in the context object.

keys()
Return a list of all variables in the context object.

values()
Return a list of all variables' values in the context object.

`items()`
Return a list of 2-tuples containing all variables and their values in the context object.

18.3 asyncio support

Context variables are natively supported in *asyncio* and are ready to be used without any extra configuration. For example, here is a simple echo server, that uses a context variable to make the address of a remote client available in the Task that handles that client:

```
import asyncio
import contextvars

client_addr_var = contextvars.ContextVar('client_addr')

def render_goodbye():
    # The address of the currently handled client can be accessed
    # without passing it explicitly to this function.

    client_addr = client_addr_var.get()
    return f'Good bye, client @ {client_addr}\n'.encode()

async def handle_request(reader, writer):
    addr = writer.transport.get_extra_info('socket').getpeername()
    client_addr_var.set(addr)

    # In any code that we call is now possible to get
    # client's address by calling 'client_addr_var.get()'.

    while True:
        line = await reader.readline()
        print(line)
        if not line.strip():
            break
        writer.write(line)

    writer.write(render_goodbye())
    writer.close()

async def main():
    srv = await asyncio.start_server(
        handle_request, '127.0.0.1', 8081)

    async with srv:
        await srv.serve_forever()

asyncio.run(main())

# To test it you can use telnet:
#     telnet 127.0.0.1 8081
```

CHAPTER

NINETEEN

INTERPROCESS COMMUNICATION AND NETWORKING

The modules described in this chapter provide mechanisms for different processes to communicate.

Some modules only work for two processes that are on the same machine, e.g. *signal* and *mmap*. Other modules support networking protocols that two or more processes can use to communicate across machines.

The list of modules described in this chapter is:

19.1 socket — Low-level networking interface

Source code: Lib/socket.py

This module provides access to the BSD *socket* interface. It is available on all modern Unix systems, Windows, MacOS, and probably additional platforms.

Note: Some behavior may be platform dependent, since calls are made to the operating system socket APIs.

The Python interface is a straightforward transliteration of the Unix system call and library interface for sockets to Python's object-oriented style: the *socket()* function returns a *socket object* whose methods implement the various socket system calls. Parameter types are somewhat higher-level than in the C interface: as with `read()` and `write()` operations on Python files, buffer allocation on receive operations is automatic, and buffer length is implicit on send operations.

See also:

Module *socketserver* Classes that simplify writing network servers.

Module *ssl* A TLS/SSL wrapper for socket objects.

19.1.1 Socket families

Depending on the system and the build options, various socket families are supported by this module.

The address format required by a particular socket object is automatically selected based on the address family specified when the socket object was created. Socket addresses are represented as follows:

- The address of an *AF_UNIX* socket bound to a file system node is represented as a string, using the file system encoding and the `'surrogateescape'` error handler (see **PEP 383**). An address in Linux's abstract namespace is returned as a *bytes-like object* with an initial null byte; note that sockets in this namespace can communicate with normal file system sockets, so programs intended to run on Linux may need to deal with both types of address. A string or bytes-like object can be used for either type of address when passing it as an argument.

Changed in version 3.3: Previously, *AF_UNIX* socket paths were assumed to use UTF-8 encoding.

Changed in version 3.5: Writable *bytes-like object* is now accepted.

- A pair `(host, port)` is used for the *AF_INET* address family, where *host* is a string representing either a hostname in Internet domain notation like `'daring.cwi.nl'` or an IPv4 address like `'100.50.200.5'`, and *port* is an integer.
- For *AF_INET6* address family, a four-tuple `(host, port, flowinfo, scopeid)` is used, where *flowinfo* and *scopeid* represent the `sin6_flowinfo` and `sin6_scope_id` members in `struct sockaddr_in6` in C. For *socket* module methods, *flowinfo* and *scopeid* can be omitted just for backward compatibility. Note, however, omission of *scopeid* can cause problems in manipulating scoped IPv6 addresses.

  Changed in version 3.7: For multicast addresses (with *scopeid* meaningful) *address* may not contain `%scope` (or `zone id`) part. This information is superfluous and may be safely omitted (recommended).
- `AF_NETLINK` sockets are represented as pairs `(pid, groups)`.
- Linux-only support for TIPC is available using the `AF_TIPC` address family. TIPC is an open, non-IP based networked protocol designed for use in clustered computer environments. Addresses are represented by a tuple, and the fields depend on the address type. The general tuple form is `(addr_type, v1, v2, v3 [, scope])`, where:
  - *addr_type* is one of `TIPC_ADDR_NAMESEQ`, `TIPC_ADDR_NAME`, or `TIPC_ADDR_ID`.
  - *scope* is one of `TIPC_ZONE_SCOPE`, `TIPC_CLUSTER_SCOPE`, and `TIPC_NODE_SCOPE`.
  - If *addr_type* is `TIPC_ADDR_NAME`, then *v1* is the server type, *v2* is the port identifier, and *v3* should be 0.

    If *addr_type* is `TIPC_ADDR_NAMESEQ`, then *v1* is the server type, *v2* is the lower port number, and *v3* is the upper port number.

    If *addr_type* is `TIPC_ADDR_ID`, then *v1* is the node, *v2* is the reference, and *v3* should be set to 0.
- A tuple `(interface, )` is used for the *AF_CAN* address family, where *interface* is a string representing a network interface name like `'can0'`. The network interface name `''` can be used to receive packets from all network interfaces of this family.
  - *CAN_ISOTP* protocol require a tuple `(interface, rx_addr, tx_addr)` where both additional parameters are unsigned long integer that represent a CAN identifier (standard or extended).
- A string or a tuple `(id, unit)` is used for the `SYSPROTO_CONTROL` protocol of the `PF_SYSTEM` family. The string is the name of a kernel control using a dynamically-assigned ID. The tuple can be used if ID and unit number of the kernel control are known or if a registered ID is used.

  New in version 3.3.
- `AF_BLUETOOTH` supports the following protocols and address formats:
  - `BTPROTO_L2CAP` accepts `(bdaddr, psm)` where `bdaddr` is the Bluetooth address as a string and `psm` is an integer.
  - `BTPROTO_RFCOMM` accepts `(bdaddr, channel)` where `bdaddr` is the Bluetooth address as a string and `channel` is an integer.
  - `BTPROTO_HCI` accepts `(device_id,)` where `device_id` is either an integer or a string with the Bluetooth address of the interface. (This depends on your OS; NetBSD and DragonFlyBSD expect a Bluetooth address while everything else expects an integer.)

    Changed in version 3.2: NetBSD and DragonFlyBSD support added.
  - `BTPROTO_SCO` accepts `bdaddr` where `bdaddr` is a *bytes* object containing the Bluetooth address in a string format. (ex. `b'12:23:34:45:56:67'`) This protocol is not supported under FreeBSD.

- *AF_ALG* is a Linux-only socket based interface to Kernel cryptography. An algorithm socket is configured with a tuple of two to four elements `(type, name [, feat [, mask]])`, where:
  - *type* is the algorithm type as string, e.g. `aead`, `hash`, `skcipher` or `rng`.
  - *name* is the algorithm name and operation mode as string, e.g. `sha256`, `hmac(sha256)`, `cbc(aes)` or `drbg_nopr_ctr_aes256`.
  - *feat* and *mask* are unsigned 32bit integers.

  Availability Linux 2.6.38, some algorithm types require more recent Kernels.

  New in version 3.6.
- *AF_VSOCK* allows communication between virtual machines and their hosts. The sockets are represented as a `(CID, port)` tuple where the context ID or CID and port are integers.

  Availability: Linux >= 4.8 QEMU >= 2.8 ESX >= 4.0 ESX Workstation >= 6.5

  New in version 3.7.
- Certain other address families (`AF_PACKET`, *AF_CAN*) support specific representations.

For IPv4 addresses, two special forms are accepted instead of a host address: the empty string represents `INADDR_ANY`, and the string `'<broadcast>'` represents `INADDR_BROADCAST`. This behavior is not compatible with IPv6, therefore, you may want to avoid these if you intend to support IPv6 with your Python programs.

If you use a hostname in the *host* portion of IPv4/v6 socket address, the program may show a nondeterministic behavior, as Python uses the first address returned from the DNS resolution. The socket address will be resolved differently into an actual IPv4/v6 address, depending on the results from DNS resolution and/or the host configuration. For deterministic behavior use a numeric address in *host* portion.

All errors raise exceptions. The normal exceptions for invalid argument types and out-of-memory conditions can be raised; starting from Python 3.3, errors related to socket or address semantics raise *OSError* or one of its subclasses (they used to raise *socket.error*).

Non-blocking mode is supported through *setblocking()*. A generalization of this based on timeouts is supported through *settimeout()*.

19.1.2 Module contents

The module *socket* exports the following elements.

Exceptions

exception socket.error
A deprecated alias of *OSError*.

Changed in version 3.3: Following **PEP 3151**, this class was made an alias of *OSError*.

exception socket.herror
A subclass of *OSError*, this exception is raised for address-related errors, i.e. for functions that use *h_errno* in the POSIX C API, including *gethostbyname_ex()* and *gethostbyaddr()*. The accompanying value is a pair `(h_errno, string)` representing an error returned by a library call. *h_errno* is a numeric value, while *string* represents the description of *h_errno*, as returned by the `hstrerror()` C function.

Changed in version 3.3: This class was made a subclass of *OSError*.

exception socket.gaierror
A subclass of *OSError*, this exception is raised for address-related errors by *getaddrinfo()* and *getnameinfo()*. The accompanying value is a pair `(error, string)` representing an error returned

by a library call. *string* represents the description of *error*, as returned by the `gai_strerror()` C function. The numeric *error* value will match one of the `EAI_*` constants defined in this module.

Changed in version 3.3: This class was made a subclass of *OSError*.

exception socket.timeout

A subclass of *OSError*, this exception is raised when a timeout occurs on a socket which has had timeouts enabled via a prior call to *settimeout()* (or implicitly through *setdefaulttimeout()*). The accompanying value is a string whose value is currently always "timed out".

Changed in version 3.3: This class was made a subclass of *OSError*.

Constants

The AF_* and SOCK_* constants are now `AddressFamily` and `SocketKind` *IntEnum* collections.

New in version 3.4.

socket.AF_UNIX
socket.AF_INET
socket.AF_INET6

These constants represent the address (and protocol) families, used for the first argument to *socket()*. If the *AF_UNIX* constant is not defined then this protocol is unsupported. More constants may be available depending on the system.

socket.SOCK_STREAM
socket.SOCK_DGRAM
socket.SOCK_RAW
socket.SOCK_RDM
socket.SOCK_SEQPACKET

These constants represent the socket types, used for the second argument to *socket()*. More constants may be available depending on the system. (Only *SOCK_STREAM* and *SOCK_DGRAM* appear to be generally useful.)

socket.SOCK_CLOEXEC
socket.SOCK_NONBLOCK

These two constants, if defined, can be combined with the socket types and allow you to set some flags atomically (thus avoiding possible race conditions and the need for separate calls).

See also:

Secure File Descriptor Handling for a more thorough explanation.

Availability: Linux >= 2.6.27.

New in version 3.2.

SO_*
socket.SOMAXCONN
MSG_*
SOL_*
SCM_*
IPPROTO_*
IPPORT_*
INADDR_*
IP_*
IPV6_*
EAI_*
AI_*
NI_*

TCP_*
: Many constants of these forms, documented in the Unix documentation on sockets and/or the IP protocol, are also defined in the socket module. They are generally used in arguments to the `setsockopt()` and `getsockopt()` methods of socket objects. In most cases, only those symbols that are defined in the Unix header files are defined; for a few symbols, default values are provided.

  Changed in version 3.6: `SO_DOMAIN`, `SO_PROTOCOL`, `SO_PEERSEC`, `SO_PASSSEC`, `TCP_USER_TIMEOUT`, `TCP_CONGESTION` were added.

  Changed in version 3.6.5: On Windows, `TCP_FASTOPEN`, `TCP_KEEPCNT` appear if run-time Windows supports.

  Changed in version 3.7: `TCP_NOTSENT_LOWAT` was added.

  On Windows, `TCP_KEEPIDLE`, `TCP_KEEPINTVL` appear if run-time Windows supports.

socket.AF_CAN
socket.PF_CAN
SOL_CAN_*
CAN_*
: Many constants of these forms, documented in the Linux documentation, are also defined in the socket module.

  Availability: Linux >= 2.6.25.

  New in version 3.3.

socket.CAN_BCM
CAN_BCM_*
: CAN_BCM, in the CAN protocol family, is the broadcast manager (BCM) protocol. Broadcast manager constants, documented in the Linux documentation, are also defined in the socket module.

  Availability: Linux >= 2.6.25.

  New in version 3.4.

socket.CAN_RAW_FD_FRAMES
: Enables CAN FD support in a CAN_RAW socket. This is disabled by default. This allows your application to send both CAN and CAN FD frames; however, you one must accept both CAN and CAN FD frames when reading from the socket.

  This constant is documented in the Linux documentation.

  Availability: Linux >= 3.6.

  New in version 3.5.

socket.CAN_ISOTP
: CAN_ISOTP, in the CAN protocol family, is the ISO-TP (ISO 15765-2) protocol. ISO-TP constants, documented in the Linux documentation.

  Availability: Linux >= 2.6.25

  New in version 3.7.

socket.AF_RDS
socket.PF_RDS
socket.SOL_RDS
RDS_*
: Many constants of these forms, documented in the Linux documentation, are also defined in the socket module.

  Availability: Linux >= 2.6.30.

  New in version 3.3.

socket.SIO_RCVALL
socket.SIO_KEEPALIVE_VALS
socket.SIO_LOOPBACK_FAST_PATH
RCVALL_*
: Constants for Windows' WSAIoctl(). The constants are used as arguments to the *ioctl()* method of socket objects.

  Changed in version 3.6: SIO_LOOPBACK_FAST_PATH was added.

TIPC_*
: TIPC related constants, matching the ones exported by the C socket API. See the TIPC documentation for more information.

socket.AF_ALG
socket.SOL_ALG
ALG_*
: Constants for Linux Kernel cryptography.

  Availability: Linux >= 2.6.38.

  New in version 3.6.

socket.AF_VSOCK
socket.IOCTL_VM_SOCKETS_GET_LOCAL_CID
VMADDR*
SO_VM*
: Constants for Linux host/guest communication.

  Availability: Linux >= 4.8.

  New in version 3.7.

socket.AF_LINK
: Availability: BSD, OSX.

  New in version 3.4.

socket.has_ipv6
: This constant contains a boolean value which indicates if IPv6 is supported on this platform.

socket.BDADDR_ANY
socket.BDADDR_LOCAL
: These are string constants containing Bluetooth addresses with special meanings. For example, *BDADDR_ANY* can be used to indicate any address when specifying the binding socket with BTPROTO_RFCOMM.

socket.HCI_FILTER
socket.HCI_TIME_STAMP
socket.HCI_DATA_DIR
: For use with BTPROTO_HCI. *HCI_FILTER* is not available for NetBSD or DragonFlyBSD. *HCI_TIME_STAMP* and *HCI_DATA_DIR* are not available for FreeBSD, NetBSD, or DragonFlyBSD.

Functions

Creating sockets

The following functions all create *socket objects*.

socket.socket(*family=AF_INET*, *type=SOCK_STREAM*, *proto=0*, *fileno=None*)
: Create a new socket using the given address family, socket type and protocol number. The address family should be *AF_INET* (the default), *AF_INET6*, *AF_UNIX*, *AF_CAN* or *AF_RDS*. The socket type should

be *SOCK_STREAM* (the default), *SOCK_DGRAM*, *SOCK_RAW* or perhaps one of the other `SOCK_` constants. The protocol number is usually zero and may be omitted or in the case where the address family is *AF_CAN* the protocol should be one of `CAN_RAW`, *CAN_BCM* or *CAN_ISOTP*

If *fileno* is specified, the values for *family*, *type*, and *proto* are auto-detected from the specified file descriptor. Auto-detection can be overruled by calling the function with explicit *family*, *type*, or *proto* arguments. This only affects how Python represents e.g. the return value of *socket.getpeername()* but not the actual OS resource. Unlike *socket.fromfd()*, *fileno* will return the same socket and not a duplicate. This may help close a detached socket using *socket.close()*.

The newly created socket is *non-inheritable*.

Changed in version 3.3: The AF_CAN family was added. The AF_RDS family was added.

Changed in version 3.4: The CAN_BCM protocol was added.

Changed in version 3.4: The returned socket is now non-inheritable.

Changed in version 3.7: The CAN_ISOTP protocol was added.

Changed in version 3.7: When *SOCK_NONBLOCK* or *SOCK_CLOEXEC* bit flags are applied to *type* they are cleared, and *socket.type* will not reflect them. They are still passed to the underlying system *socket()* call. Therefore::

sock = socket.socket(socket.AF_INET, socket.SOCK_STREAM | socket.SOCK_NONBLOCK)

will still create a non-blocking socket on OSes that support `SOCK_NONBLOCK`, but `sock.type` will be set to `socket.SOCK_STREAM`.

`socket.socketpair`([*family*[, *type*[, *proto*]]])
Build a pair of connected socket objects using the given address family, socket type, and protocol number. Address family, socket type, and protocol number are as for the *socket()* function above. The default family is *AF_UNIX* if defined on the platform; otherwise, the default is *AF_INET*.

The newly created sockets are *non-inheritable*.

Changed in version 3.2: The returned socket objects now support the whole socket API, rather than a subset.

Changed in version 3.4: The returned sockets are now non-inheritable.

Changed in version 3.5: Windows support added.

`socket.create_connection`(*address*[, *timeout*[, *source_address*]])
Connect to a TCP service listening on the Internet *address* (a 2-tuple `(host, port)`), and return the socket object. This is a higher-level function than *socket.connect()*: if *host* is a non-numeric hostname, it will try to resolve it for both *AF_INET* and *AF_INET6*, and then try to connect to all possible addresses in turn until a connection succeeds. This makes it easy to write clients that are compatible to both IPv4 and IPv6.

Passing the optional *timeout* parameter will set the timeout on the socket instance before attempting to connect. If no *timeout* is supplied, the global default timeout setting returned by *getdefaulttimeout()* is used.

If supplied, *source_address* must be a 2-tuple `(host, port)` for the socket to bind to as its source address before connecting. If host or port are '' or 0 respectively the OS default behavior will be used.

Changed in version 3.2: *source_address* was added.

`socket.fromfd`(*fd*, *family*, *type*, *proto=0*)
Duplicate the file descriptor *fd* (an integer as returned by a file object's `fileno()` method) and build a socket object from the result. Address family, socket type and protocol number are as for the *socket()* function above. The file descriptor should refer to a socket, but this is not checked — subsequent operations on the object may fail if the file descriptor is invalid. This function is rarely

needed, but can be used to get or set socket options on a socket passed to a program as standard input or output (such as a server started by the Unix inet daemon). The socket is assumed to be in blocking mode.

The newly created socket is *non-inheritable*.

Changed in version 3.4: The returned socket is now non-inheritable.

`socket.fromshare`(*data*)
Instantiate a socket from data obtained from the *socket.share()* method. The socket is assumed to be in blocking mode.

Availability: Windows.

New in version 3.3.

`socket.SocketType`
This is a Python type object that represents the socket object type. It is the same as `type(socket(...))`.

Other functions

The *socket* module also offers various network-related services:

`socket.close`(*fd*)
Close a socket file descriptor. This is like *os.close()*, but for sockets. On some platforms (most noticeable Windows) *os.close()* does not work for socket file descriptors.

New in version 3.7.

`socket.getaddrinfo`(*host*, *port*, *family=0*, *type=0*, *proto=0*, *flags=0*)
Translate the *host*/*port* argument into a sequence of 5-tuples that contain all the necessary arguments for creating a socket connected to that service. *host* is a domain name, a string representation of an IPv4/v6 address or `None`. *port* is a string service name such as `'http'`, a numeric port number or `None`. By passing `None` as the value of *host* and *port*, you can pass `NULL` to the underlying C API.

The *family*, *type* and *proto* arguments can be optionally specified in order to narrow the list of addresses returned. Passing zero as a value for each of these arguments selects the full range of results. The *flags* argument can be one or several of the `AI_*` constants, and will influence how results are computed and returned. For example, `AI_NUMERICHOST` will disable domain name resolution and will raise an error if *host* is a domain name.

The function returns a list of 5-tuples with the following structure:

`(family, type, proto, canonname, sockaddr)`

In these tuples, *family*, *type*, *proto* are all integers and are meant to be passed to the *socket()* function. *canonname* will be a string representing the canonical name of the *host* if `AI_CANONNAME` is part of the *flags* argument; else *canonname* will be empty. *sockaddr* is a tuple describing a socket address, whose format depends on the returned *family* (a `(address, port)` 2-tuple for *AF_INET*, a `(address, port, flow info, scope id)` 4-tuple for *AF_INET6*), and is meant to be passed to the *socket.connect()* method.

The following example fetches address information for a hypothetical TCP connection to `example.org` on port 80 (results may differ on your system if IPv6 isn't enabled):

```
>>> socket.getaddrinfo("example.org", 80, proto=socket.IPPROTO_TCP)
[(<AddressFamily.AF_INET6: 10>, <SocketType.SOCK_STREAM: 1>,
 6, '', ('2606:2800:220:1:248:1893:25c8:1946', 80, 0, 0)),
 (<AddressFamily.AF_INET: 2>, <SocketType.SOCK_STREAM: 1>,
 6, '', ('93.184.216.34', 80))]
```

Changed in version 3.2: parameters can now be passed using keyword arguments.

Changed in version 3.7: for IPv6 multicast addresses, string representing an address will not contain `%scope` part.

`socket.getfqdn([name])`
Return a fully qualified domain name for *name*. If *name* is omitted or empty, it is interpreted as the local host. To find the fully qualified name, the hostname returned by *gethostbyaddr()* is checked, followed by aliases for the host, if available. The first name which includes a period is selected. In case no fully qualified domain name is available, the hostname as returned by *gethostname()* is returned.

`socket.gethostbyname(hostname)`
Translate a host name to IPv4 address format. The IPv4 address is returned as a string, such as `'100.50.200.5'`. If the host name is an IPv4 address itself it is returned unchanged. See *gethostbyname_ex()* for a more complete interface. *gethostbyname()* does not support IPv6 name resolution, and *getaddrinfo()* should be used instead for IPv4/v6 dual stack support.

`socket.gethostbyname_ex(hostname)`
Translate a host name to IPv4 address format, extended interface. Return a triple `(hostname, aliaslist, ipaddrlist)` where *hostname* is the primary host name responding to the given *ip_address*, *aliaslist* is a (possibly empty) list of alternative host names for the same address, and *ipaddrlist* is a list of IPv4 addresses for the same interface on the same host (often but not always a single address). *gethostbyname_ex()* does not support IPv6 name resolution, and *getaddrinfo()* should be used instead for IPv4/v6 dual stack support.

`socket.gethostname()`
Return a string containing the hostname of the machine where the Python interpreter is currently executing.

Note: *gethostname()* doesn't always return the fully qualified domain name; use *getfqdn()* for that.

`socket.gethostbyaddr(ip_address)`
Return a triple `(hostname, aliaslist, ipaddrlist)` where *hostname* is the primary host name responding to the given *ip_address*, *aliaslist* is a (possibly empty) list of alternative host names for the same address, and *ipaddrlist* is a list of IPv4/v6 addresses for the same interface on the same host (most likely containing only a single address). To find the fully qualified domain name, use the function *getfqdn()*. *gethostbyaddr()* supports both IPv4 and IPv6.

`socket.getnameinfo(sockaddr, flags)`
Translate a socket address *sockaddr* into a 2-tuple `(host, port)`. Depending on the settings of *flags*, the result can contain a fully-qualified domain name or numeric address representation in *host*. Similarly, *port* can contain a string port name or a numeric port number.

For IPv6 addresses, `%scope` is appended to the host part if *sockaddr* contains meaningful *scopeid*. Usually this happens for multicast addresses.

`socket.getprotobyname(protocolname)`
Translate an Internet protocol name (for example, `'icmp'`) to a constant suitable for passing as the (optional) third argument to the *socket()* function. This is usually only needed for sockets opened in "raw" mode (*SOCK_RAW*); for the normal socket modes, the correct protocol is chosen automatically if the protocol is omitted or zero.

`socket.getservbyname(servicename[, protocolname])`
Translate an Internet service name and protocol name to a port number for that service. The optional protocol name, if given, should be `'tcp'` or `'udp'`, otherwise any protocol will match.

`socket.getservbyport(port[, protocolname])`
Translate an Internet port number and protocol name to a service name for that service. The optional protocol name, if given, should be `'tcp'` or `'udp'`, otherwise any protocol will match.

socket.ntohl(*x*)
Convert 32-bit positive integers from network to host byte order. On machines where the host byte order is the same as network byte order, this is a no-op; otherwise, it performs a 4-byte swap operation.

socket.ntohs(*x*)
Convert 16-bit positive integers from network to host byte order. On machines where the host byte order is the same as network byte order, this is a no-op; otherwise, it performs a 2-byte swap operation.

Deprecated since version 3.7: In case *x* does not fit in 16-bit unsigned integer, but does fit in a positive C int, it is silently truncated to 16-bit unsigned integer. This silent truncation feature is deprecated, and will raise an exception in future versions of Python.

socket.htonl(*x*)
Convert 32-bit positive integers from host to network byte order. On machines where the host byte order is the same as network byte order, this is a no-op; otherwise, it performs a 4-byte swap operation.

socket.htons(*x*)
Convert 16-bit positive integers from host to network byte order. On machines where the host byte order is the same as network byte order, this is a no-op; otherwise, it performs a 2-byte swap operation.

Deprecated since version 3.7: In case *x* does not fit in 16-bit unsigned integer, but does fit in a positive C int, it is silently truncated to 16-bit unsigned integer. This silent truncation feature is deprecated, and will raise an exception in future versions of Python.

socket.inet_aton(*ip_string*)
Convert an IPv4 address from dotted-quad string format (for example, '123.45.67.89') to 32-bit packed binary format, as a bytes object four characters in length. This is useful when conversing with a program that uses the standard C library and needs objects of type `struct in_addr`, which is the C type for the 32-bit packed binary this function returns.

inet_aton() also accepts strings with less than three dots; see the Unix manual page *inet(3)* for details.

If the IPv4 address string passed to this function is invalid, *OSError* will be raised. Note that exactly what is valid depends on the underlying C implementation of `inet_aton()`.

inet_aton() does not support IPv6, and *inet_pton()* should be used instead for IPv4/v6 dual stack support.

socket.inet_ntoa(*packed_ip*)
Convert a 32-bit packed IPv4 address (a *bytes-like object* four bytes in length) to its standard dotted-quad string representation (for example, '123.45.67.89'). This is useful when conversing with a program that uses the standard C library and needs objects of type `struct in_addr`, which is the C type for the 32-bit packed binary data this function takes as an argument.

If the byte sequence passed to this function is not exactly 4 bytes in length, *OSError* will be raised. *inet_ntoa()* does not support IPv6, and *inet_ntop()* should be used instead for IPv4/v6 dual stack support.

Changed in version 3.5: Writable *bytes-like object* is now accepted.

socket.inet_pton(*address_family*, *ip_string*)
Convert an IP address from its family-specific string format to a packed, binary format. *inet_pton()* is useful when a library or network protocol calls for an object of type `struct in_addr` (similar to *inet_aton()*) or `struct in6_addr`.

Supported values for *address_family* are currently *AF_INET* and *AF_INET6*. If the IP address string *ip_string* is invalid, *OSError* will be raised. Note that exactly what is valid depends on both the value of *address_family* and the underlying implementation of `inet_pton()`.

Availability: Unix (maybe not all platforms), Windows.

Changed in version 3.4: Windows support added

socket.**inet_ntop**(*address_family*, *packed_ip*)
Convert a packed IP address (a *bytes-like object* of some number of bytes) to its standard, family-specific string representation (for example, `'7.10.0.5'` or `'5aef:2b::8'`). *inet_ntop()* is useful when a library or network protocol returns an object of type `struct in_addr` (similar to *inet_ntoa()*) or `struct in6_addr`.

Supported values for *address_family* are currently *AF_INET* and *AF_INET6*. If the bytes object *packed_ip* is not the correct length for the specified address family, *ValueError* will be raised. *OSError* is raised for errors from the call to *inet_ntop()*.

Availability: Unix (maybe not all platforms), Windows.

Changed in version 3.4: Windows support added

Changed in version 3.5: Writable *bytes-like object* is now accepted.

socket.**CMSG_LEN**(*length*)
Return the total length, without trailing padding, of an ancillary data item with associated data of the given *length*. This value can often be used as the buffer size for *recvmsg()* to receive a single item of ancillary data, but **RFC 3542** requires portable applications to use *CMSG_SPACE()* and thus include space for padding, even when the item will be the last in the buffer. Raises *OverflowError* if *length* is outside the permissible range of values.

Availability: most Unix platforms, possibly others.

New in version 3.3.

socket.**CMSG_SPACE**(*length*)
Return the buffer size needed for *recvmsg()* to receive an ancillary data item with associated data of the given *length*, along with any trailing padding. The buffer space needed to receive multiple items is the sum of the *CMSG_SPACE()* values for their associated data lengths. Raises *OverflowError* if *length* is outside the permissible range of values.

Note that some systems might support ancillary data without providing this function. Also note that setting the buffer size using the results of this function may not precisely limit the amount of ancillary data that can be received, since additional data may be able to fit into the padding area.

Availability: most Unix platforms, possibly others.

New in version 3.3.

socket.**getdefaulttimeout**()
Return the default timeout in seconds (float) for new socket objects. A value of `None` indicates that new socket objects have no timeout. When the socket module is first imported, the default is `None`.

socket.**setdefaulttimeout**(*timeout*)
Set the default timeout in seconds (float) for new socket objects. When the socket module is first imported, the default is `None`. See *settimeout()* for possible values and their respective meanings.

socket.**sethostname**(*name*)
Set the machine's hostname to *name*. This will raise an *OSError* if you don't have enough rights.

Availability: Unix.

New in version 3.3.

socket.**if_nameindex**()
Return a list of network interface information (index int, name string) tuples. *OSError* if the system call fails.

Availability: Unix.

New in version 3.3.

`socket.if_nametoindex(if_name)`
Return a network interface index number corresponding to an interface name. *OSError* if no interface with the given name exists.

Availability: Unix.

New in version 3.3.

`socket.if_indextoname(if_index)`
Return a network interface name corresponding to an interface index number. *OSError* if no interface with the given index exists.

Availability: Unix.

New in version 3.3.

19.1.3 Socket Objects

Socket objects have the following methods. Except for *makefile()*, these correspond to Unix system calls applicable to sockets.

Changed in version 3.2: Support for the *context manager* protocol was added. Exiting the context manager is equivalent to calling *close()*.

`socket.accept()`
Accept a connection. The socket must be bound to an address and listening for connections. The return value is a pair `(conn, address)` where *conn* is a *new* socket object usable to send and receive data on the connection, and *address* is the address bound to the socket on the other end of the connection.

The newly created socket is *non-inheritable*.

Changed in version 3.4: The socket is now non-inheritable.

Changed in version 3.5: If the system call is interrupted and the signal handler does not raise an exception, the method now retries the system call instead of raising an *InterruptedError* exception (see **PEP 475** for the rationale).

`socket.bind(address)`
Bind the socket to *address*. The socket must not already be bound. (The format of *address* depends on the address family — see above.)

`socket.close()`
Mark the socket closed. The underlying system resource (e.g. a file descriptor) is also closed when all file objects from *makefile()* are closed. Once that happens, all future operations on the socket object will fail. The remote end will receive no more data (after queued data is flushed).

Sockets are automatically closed when they are garbage-collected, but it is recommended to *close()* them explicitly, or to use a `with` statement around them.

Changed in version 3.6: *OSError* is now raised if an error occurs when the underlying `close()` call is made.

Note: *close()* releases the resource associated with a connection but does not necessarily close the connection immediately. If you want to close the connection in a timely fashion, call *shutdown()* before *close()*.

`socket.connect(address)`
Connect to a remote socket at *address*. (The format of *address* depends on the address family — see above.)

If the connection is interrupted by a signal, the method waits until the connection completes, or raise a *socket.timeout* on timeout, if the signal handler doesn't raise an exception and the socket is blocking or has a timeout. For non-blocking sockets, the method raises an *InterruptedError* exception if the connection is interrupted by a signal (or the exception raised by the signal handler).

Changed in version 3.5: The method now waits until the connection completes instead of raising an *InterruptedError* exception if the connection is interrupted by a signal, the signal handler doesn't raise an exception and the socket is blocking or has a timeout (see the **PEP 475** for the rationale).

`socket.connect_ex(`*address*`)`
Like `connect(address)`, but return an error indicator instead of raising an exception for errors returned by the C-level `connect()` call (other problems, such as "host not found," can still raise exceptions). The error indicator is `0` if the operation succeeded, otherwise the value of the `errno` variable. This is useful to support, for example, asynchronous connects.

`socket.detach()`
Put the socket object into closed state without actually closing the underlying file descriptor. The file descriptor is returned, and can be reused for other purposes.

New in version 3.2.

`socket.dup()`
Duplicate the socket.

The newly created socket is *non-inheritable*.

Changed in version 3.4: The socket is now non-inheritable.

`socket.fileno()`
Return the socket's file descriptor (a small integer), or -1 on failure. This is useful with *select.select()*.

Under Windows the small integer returned by this method cannot be used where a file descriptor can be used (such as *os.fdopen()*). Unix does not have this limitation.

`socket.get_inheritable()`
Get the *inheritable flag* of the socket's file descriptor or socket's handle: `True` if the socket can be inherited in child processes, `False` if it cannot.

New in version 3.4.

`socket.getpeername()`
Return the remote address to which the socket is connected. This is useful to find out the port number of a remote IPv4/v6 socket, for instance. (The format of the address returned depends on the address family — see above.) On some systems this function is not supported.

`socket.getsockname()`
Return the socket's own address. This is useful to find out the port number of an IPv4/v6 socket, for instance. (The format of the address returned depends on the address family — see above.)

`socket.getsockopt(`*level*, *optname*[, *buflen*]`)`
Return the value of the given socket option (see the Unix man page *getsockopt(2)*). The needed symbolic constants (`SO_*` etc.) are defined in this module. If *buflen* is absent, an integer option is assumed and its integer value is returned by the function. If *buflen* is present, it specifies the maximum length of the buffer used to receive the option in, and this buffer is returned as a bytes object. It is up to the caller to decode the contents of the buffer (see the optional built-in module *struct* for a way to decode C structures encoded as byte strings).

`socket.getblocking()`
Return `True` if socket is in blocking mode, `False` if in non-blocking.

This is equivalent to checking `socket.gettimeout() == 0`.

New in version 3.7.

socket.gettimeout()
Return the timeout in seconds (float) associated with socket operations, or None if no timeout is set. This reflects the last call to *setblocking()* or *settimeout()*.

socket.ioctl(*control*, *option*)

Platform Windows

The *ioctl()* method is a limited interface to the WSAIoctl system interface. Please refer to the Win32 documentation for more information.

On other platforms, the generic *fcntl.fcntl()* and *fcntl.ioctl()* functions may be used; they accept a socket object as their first argument.

Currently only the following control codes are supported: SIO_RCVALL, SIO_KEEPALIVE_VALS, and SIO_LOOPBACK_FAST_PATH.

Changed in version 3.6: SIO_LOOPBACK_FAST_PATH was added.

socket.listen([*backlog*])
Enable a server to accept connections. If *backlog* is specified, it must be at least 0 (if it is lower, it is set to 0); it specifies the number of unaccepted connections that the system will allow before refusing new connections. If not specified, a default reasonable value is chosen.

Changed in version 3.5: The *backlog* parameter is now optional.

socket.makefile(*mode='r'*, *buffering=None*, ***, *encoding=None*, *errors=None*, *newline=None*)
Return a *file object* associated with the socket. The exact returned type depends on the arguments given to *makefile()*. These arguments are interpreted the same way as by the built-in *open()* function, except the only supported *mode* values are 'r' (default), 'w' and 'b'.

The socket must be in blocking mode; it can have a timeout, but the file object's internal buffer may end up in an inconsistent state if a timeout occurs.

Closing the file object returned by *makefile()* won't close the original socket unless all other file objects have been closed and *socket.close()* has been called on the socket object.

Note: On Windows, the file-like object created by *makefile()* cannot be used where a file object with a file descriptor is expected, such as the stream arguments of *subprocess.Popen()*.

---

socket.recv(*bufsize*[, *flags*])
Receive data from the socket. The return value is a bytes object representing the data received. The maximum amount of data to be received at once is specified by *bufsize*. See the Unix manual page *recv(2)* for the meaning of the optional argument *flags*; it defaults to zero.

Note: For best match with hardware and network realities, the value of *bufsize* should be a relatively small power of 2, for example, 4096.

Changed in version 3.5: If the system call is interrupted and the signal handler does not raise an exception, the method now retries the system call instead of raising an *InterruptedError* exception (see **PEP 475** for the rationale).

socket.recvfrom(*bufsize*[, *flags*])
Receive data from the socket. The return value is a pair (bytes, address) where *bytes* is a bytes object representing the data received and *address* is the address of the socket sending the data. See the Unix manual page *recv(2)* for the meaning of the optional argument *flags*; it defaults to zero. (The format of *address* depends on the address family — see above.)

Changed in version 3.5: If the system call is interrupted and the signal handler does not raise an exception, the method now retries the system call instead of raising an *InterruptedError* exception (see **PEP 475** for the rationale).

Changed in version 3.7: For multicast IPv6 address, first item of *address* does not contain `%scope` part anymore. In order to get full IPv6 address use *getnameinfo()*.

`socket.recvmsg`(*bufsize*[, *ancbufsize*[, *flags*]])

Receive normal data (up to *bufsize* bytes) and ancillary data from the socket. The *ancbufsize* argument sets the size in bytes of the internal buffer used to receive the ancillary data; it defaults to 0, meaning that no ancillary data will be received. Appropriate buffer sizes for ancillary data can be calculated using *CMSG_SPACE()* or *CMSG_LEN()*, and items which do not fit into the buffer might be truncated or discarded. The *flags* argument defaults to 0 and has the same meaning as for *recv()*.

The return value is a 4-tuple: `(data, ancdata, msg_flags, address)`. The *data* item is a *bytes* object holding the non-ancillary data received. The *ancdata* item is a list of zero or more tuples `(cmsg_level, cmsg_type, cmsg_data)` representing the ancillary data (control messages) received: *cmsg_level* and *cmsg_type* are integers specifying the protocol level and protocol-specific type respectively, and *cmsg_data* is a *bytes* object holding the associated data. The *msg_flags* item is the bitwise OR of various flags indicating conditions on the received message; see your system documentation for details. If the receiving socket is unconnected, *address* is the address of the sending socket, if available; otherwise, its value is unspecified.

On some systems, *sendmsg()* and *recvmsg()* can be used to pass file descriptors between processes over an *AF_UNIX* socket. When this facility is used (it is often restricted to *SOCK_STREAM* sockets), *recvmsg()* will return, in its ancillary data, items of the form `(socket.SOL_SOCKET, socket.SCM_RIGHTS, fds)`, where *fds* is a *bytes* object representing the new file descriptors as a binary array of the native C `int` type. If *recvmsg()* raises an exception after the system call returns, it will first attempt to close any file descriptors received via this mechanism.

Some systems do not indicate the truncated length of ancillary data items which have been only partially received. If an item appears to extend beyond the end of the buffer, *recvmsg()* will issue a *RuntimeWarning*, and will return the part of it which is inside the buffer provided it has not been truncated before the start of its associated data.

On systems which support the `SCM_RIGHTS` mechanism, the following function will receive up to *maxfds* file descriptors, returning the message data and a list containing the descriptors (while ignoring unexpected conditions such as unrelated control messages being received). See also *sendmsg()*.

```
import socket, array

def recv_fds(sock, msglen, maxfds):
    fds = array.array("i")   # Array of ints
    msg, ancdata, flags, addr = sock.recvmsg(msglen, socket.CMSG_LEN(maxfds * fds.itemsize))
    for cmsg_level, cmsg_type, cmsg_data in ancdata:
        if (cmsg_level == socket.SOL_SOCKET and cmsg_type == socket.SCM_RIGHTS):
            # Append data, ignoring any truncated integers at the end.
            fds.fromstring(cmsg_data[:len(cmsg_data) - (len(cmsg_data) % fds.itemsize)])
    return msg, list(fds)
```

Availability: most Unix platforms, possibly others.

New in version 3.3.

Changed in version 3.5: If the system call is interrupted and the signal handler does not raise an exception, the method now retries the system call instead of raising an *InterruptedError* exception (see **PEP 475** for the rationale).

`socket.recvmsg_into`(*buffers*[, *ancbufsize*[, *flags*]])

Receive normal data and ancillary data from the socket, behaving as *recvmsg()* would, but scatter

the non-ancillary data into a series of buffers instead of returning a new bytes object. The *buffers* argument must be an iterable of objects that export writable buffers (e.g. *bytearray* objects); these will be filled with successive chunks of the non-ancillary data until it has all been written or there are no more buffers. The operating system may set a limit (*sysconf()* value `SC_IOV_MAX`) on the number of buffers that can be used. The *ancbufsize* and *flags* arguments have the same meaning as for *recvmsg()*.

The return value is a 4-tuple: `(nbytes, ancdata, msg_flags, address)`, where *nbytes* is the total number of bytes of non-ancillary data written into the buffers, and *ancdata*, *msg_flags* and *address* are the same as for *recvmsg()*.

Example:

```
>>> import socket
>>> s1, s2 = socket.socketpair()
>>> b1 = bytearray(b'----')
>>> b2 = bytearray(b'0123456789')
>>> b3 = bytearray(b'--------------')
>>> s1.send(b'Mary had a little lamb')
22
>>> s2.recvmsg_into([b1, memoryview(b2)[2:9], b3])
(22, [], 0, None)
>>> [b1, b2, b3]
[bytearray(b'Mary'), bytearray(b'01 had a 9'), bytearray(b'little lamb---')]
```

Availability: most Unix platforms, possibly others.

New in version 3.3.

`socket.recvfrom_into(`*buffer*[, *nbytes*[, *flags*]]`)`

Receive data from the socket, writing it into *buffer* instead of creating a new bytestring. The return value is a pair `(nbytes, address)` where *nbytes* is the number of bytes received and *address* is the address of the socket sending the data. See the Unix manual page *recv(2)* for the meaning of the optional argument *flags*; it defaults to zero. (The format of *address* depends on the address family — see above.)

`socket.recv_into(`*buffer*[, *nbytes*[, *flags*]]`)`

Receive up to *nbytes* bytes from the socket, storing the data into a buffer rather than creating a new bytestring. If *nbytes* is not specified (or 0), receive up to the size available in the given buffer. Returns the number of bytes received. See the Unix manual page *recv(2)* for the meaning of the optional argument *flags*; it defaults to zero.

`socket.send(`*bytes*[, *flags*]`)`

Send data to the socket. The socket must be connected to a remote socket. The optional *flags* argument has the same meaning as for *recv()* above. Returns the number of bytes sent. Applications are responsible for checking that all data has been sent; if only some of the data was transmitted, the application needs to attempt delivery of the remaining data. For further information on this topic, consult the socket-howto.

Changed in version 3.5: If the system call is interrupted and the signal handler does not raise an exception, the method now retries the system call instead of raising an *InterruptedError* exception (see **PEP 475** for the rationale).

`socket.sendall(`*bytes*[, *flags*]`)`

Send data to the socket. The socket must be connected to a remote socket. The optional *flags* argument has the same meaning as for *recv()* above. Unlike *send()*, this method continues to send data from *bytes* until either all data has been sent or an error occurs. `None` is returned on success. On error, an exception is raised, and there is no way to determine how much data, if any, was successfully sent.

Changed in version 3.5: The socket timeout is no more reset each time data is sent successfully. The socket timeout is now the maximum total duration to send all data.

Changed in version 3.5: If the system call is interrupted and the signal handler does not raise an exception, the method now retries the system call instead of raising an *InterruptedError* exception (see **PEP 475** for the rationale).

socket.sendto(*bytes*, *address*)
socket.sendto(*bytes*, *flags*, *address*)
Send data to the socket. The socket should not be connected to a remote socket, since the destination socket is specified by *address*. The optional *flags* argument has the same meaning as for *recv()* above. Return the number of bytes sent. (The format of *address* depends on the address family — see above.)

Changed in version 3.5: If the system call is interrupted and the signal handler does not raise an exception, the method now retries the system call instead of raising an *InterruptedError* exception (see **PEP 475** for the rationale).

socket.sendmsg(*buffers*[, *ancdata*[, *flags*[, *address*]]])
Send normal and ancillary data to the socket, gathering the non-ancillary data from a series of buffers and concatenating it into a single message. The *buffers* argument specifies the non-ancillary data as an iterable of *bytes-like objects* (e.g. *bytes* objects); the operating system may set a limit (*sysconf()* value `SC_IOV_MAX`) on the number of buffers that can be used. The *ancdata* argument specifies the ancillary data (control messages) as an iterable of zero or more tuples `(cmsg_level, cmsg_type, cmsg_data)`, where *cmsg_level* and *cmsg_type* are integers specifying the protocol level and protocol-specific type respectively, and *cmsg_data* is a bytes-like object holding the associated data. Note that some systems (in particular, systems without *CMSG_SPACE()*) might support sending only one control message per call. The *flags* argument defaults to 0 and has the same meaning as for *send()*. If *address* is supplied and not `None`, it sets a destination address for the message. The return value is the number of bytes of non-ancillary data sent.

The following function sends the list of file descriptors *fds* over an *AF_UNIX* socket, on systems which support the `SCM_RIGHTS` mechanism. See also *recvmsg()*.

```
import socket, array

def send_fds(sock, msg, fds):
    return sock.sendmsg([msg], [(socket.SOL_SOCKET, socket.SCM_RIGHTS, array.array("i",␣
↪fds))])
```

Availability: most Unix platforms, possibly others.

New in version 3.3.

Changed in version 3.5: If the system call is interrupted and the signal handler does not raise an exception, the method now retries the system call instead of raising an *InterruptedError* exception (see **PEP 475** for the rationale).

socket.sendmsg_afalg([*msg*], *, *op*[, *iv*[, *assoclen*[, *flags*]]])
Specialized version of *sendmsg()* for *AF_ALG* socket. Set mode, IV, AEAD associated data length and flags for *AF_ALG* socket.

Availability: Linux >= 2.6.38

New in version 3.6.

socket.sendfile(*file*, *offset=0*, *count=None*)
Send a file until EOF is reached by using high-performance *os.sendfile* and return the total number of bytes which were sent. *file* must be a regular file object opened in binary mode. If *os.sendfile* is not available (e.g. Windows) or *file* is not a regular file *send()* will be used instead. *offset* tells from where to start reading the file. If specified, *count* is the total number of bytes to transmit as opposed to sending the file until EOF is reached. File position is updated on return or also in case of error in

which case *file.tell()* can be used to figure out the number of bytes which were sent. The socket must be of *SOCK_STREAM* type. Non-blocking sockets are not supported.

New in version 3.5.

socket.set_inheritable(*inheritable*)
Set the *inheritable flag* of the socket's file descriptor or socket's handle.

New in version 3.4.

socket.setblocking(*flag*)
Set blocking or non-blocking mode of the socket: if *flag* is false, the socket is set to non-blocking, else to blocking mode.

This method is a shorthand for certain *settimeout()* calls:

- `sock.setblocking(True)` is equivalent to `sock.settimeout(None)`
- `sock.setblocking(False)` is equivalent to `sock.settimeout(0.0)`

Changed in version 3.7: The method no longer applies *SOCK_NONBLOCK* flag on *socket.type*.

socket.settimeout(*value*)
Set a timeout on blocking socket operations. The *value* argument can be a nonnegative floating point number expressing seconds, or `None`. If a non-zero value is given, subsequent socket operations will raise a *timeout* exception if the timeout period *value* has elapsed before the operation has completed. If zero is given, the socket is put in non-blocking mode. If `None` is given, the socket is put in blocking mode.

For further information, please consult the *notes on socket timeouts*.

Changed in version 3.7: The method no longer toggles *SOCK_NONBLOCK* flag on *socket.type*.

socket.setsockopt(*level*, *optname*, *value: int*)

socket.setsockopt(*level*, *optname*, *value: buffer*)

socket.setsockopt(*level*, *optname*, *None*, *optlen: int*)
Set the value of the given socket option (see the Unix manual page *setsockopt(2)*). The needed symbolic constants are defined in the *socket* module (`SO_*` etc.). The value can be an integer, `None` or a *bytes-like object* representing a buffer. In the later case it is up to the caller to ensure that the bytestring contains the proper bits (see the optional built-in module *struct* for a way to encode C structures as bytestrings). When value is set to `None`, optlen argument is required. It's equivalent to call setsockopt C function with optval=NULL and optlen=optlen.

Changed in version 3.5: Writable *bytes-like object* is now accepted.

Changed in version 3.6: setsockopt(level, optname, None, optlen: int) form added.

socket.shutdown(*how*)
Shut down one or both halves of the connection. If *how* is `SHUT_RD`, further receives are disallowed. If *how* is `SHUT_WR`, further sends are disallowed. If *how* is `SHUT_RDWR`, further sends and receives are disallowed.

socket.share(*process_id*)
Duplicate a socket and prepare it for sharing with a target process. The target process must be provided with *process_id*. The resulting bytes object can then be passed to the target process using some form of interprocess communication and the socket can be recreated there using *fromshare()*. Once this method has been called, it is safe to close the socket since the operating system has already duplicated it for the target process.

Availability: Windows.

New in version 3.3.

Note that there are no methods `read()` or `write()`; use *recv()* and *send()* without *flags* argument instead.

Socket objects also have these (read-only) attributes that correspond to the values given to the *socket* constructor.

`socket.family`
The socket family.

`socket.type`
The socket type.

`socket.proto`
The socket protocol.

19.1.4 Notes on socket timeouts

A socket object can be in one of three modes: blocking, non-blocking, or timeout. Sockets are by default always created in blocking mode, but this can be changed by calling *setdefaulttimeout()*.

- In *blocking mode*, operations block until complete or the system returns an error (such as connection timed out).
- In *non-blocking mode*, operations fail (with an error that is unfortunately system-dependent) if they cannot be completed immediately: functions from the *select* can be used to know when and whether a socket is available for reading or writing.
- In *timeout mode*, operations fail if they cannot be completed within the timeout specified for the socket (they raise a *timeout* exception) or if the system returns an error.

Note: At the operating system level, sockets in *timeout mode* are internally set in non-blocking mode. Also, the blocking and timeout modes are shared between file descriptors and socket objects that refer to the same network endpoint. This implementation detail can have visible consequences if e.g. you decide to use the *fileno()* of a socket.

Timeouts and the `connect` method

The *connect()* operation is also subject to the timeout setting, and in general it is recommended to call *settimeout()* before calling *connect()* or pass a timeout parameter to *create_connection()*. However, the system network stack may also return a connection timeout error of its own regardless of any Python socket timeout setting.

Timeouts and the `accept` method

If *getdefaulttimeout()* is not *None*, sockets returned by the *accept()* method inherit that timeout. Otherwise, the behaviour depends on settings of the listening socket:

- if the listening socket is in *blocking mode* or in *timeout mode*, the socket returned by *accept()* is in *blocking mode*;
- if the listening socket is in *non-blocking mode*, whether the socket returned by *accept()* is in blocking or non-blocking mode is operating system-dependent. If you want to ensure cross-platform behaviour, it is recommended you manually override this setting.

19.1.5 Example

Here are four minimal example programs using the TCP/IP protocol: a server that echoes all data that it receives back (servicing only one client), and a client using it. Note that a server must perform the sequence *socket()*, *bind()*, *listen()*, *accept()* (possibly repeating the *accept()* to service more than one client), while a client only needs the sequence *socket()*, *connect()*. Also note that the server does not *sendall()*/*recv()* on the socket it is listening on but on the new socket returned by *accept()*.

The first two examples support IPv4 only.

```
# Echo server program
import socket

HOST = ''                 # Symbolic name meaning all available interfaces
PORT = 50007              # Arbitrary non-privileged port
with socket.socket(socket.AF_INET, socket.SOCK_STREAM) as s:
    s.bind((HOST, PORT))
    s.listen(1)
    conn, addr = s.accept()
    with conn:
        print('Connected by', addr)
        while True:
            data = conn.recv(1024)
            if not data: break
            conn.sendall(data)
```

```
# Echo client program
import socket

HOST = 'daring.cwi.nl'    # The remote host
PORT = 50007              # The same port as used by the server
with socket.socket(socket.AF_INET, socket.SOCK_STREAM) as s:
    s.connect((HOST, PORT))
    s.sendall(b'Hello, world')
    data = s.recv(1024)
print('Received', repr(data))
```

The next two examples are identical to the above two, but support both IPv4 and IPv6. The server side will listen to the first address family available (it should listen to both instead). On most of IPv6-ready systems, IPv6 will take precedence and the server may not accept IPv4 traffic. The client side will try to connect to the all addresses returned as a result of the name resolution, and sends traffic to the first one connected successfully.

```
# Echo server program
import socket
import sys

HOST = None               # Symbolic name meaning all available interfaces
PORT = 50007              # Arbitrary non-privileged port
s = None
for res in socket.getaddrinfo(HOST, PORT, socket.AF_UNSPEC,
                              socket.SOCK_STREAM, 0, socket.AI_PASSIVE):
    af, socktype, proto, canonname, sa = res
    try:
        s = socket.socket(af, socktype, proto)
    except OSError as msg:
        s = None
```

(continues on next page)

(continued from previous page)

```
        continue
    try:
        s.bind(sa)
        s.listen(1)
    except OSError as msg:
        s.close()
        s = None
        continue
    break
if s is None:
    print('could not open socket')
    sys.exit(1)
conn, addr = s.accept()
with conn:
    print('Connected by', addr)
    while True:
        data = conn.recv(1024)
        if not data: break
        conn.send(data)
```

```
# Echo client program
import socket
import sys

HOST = 'daring.cwi.nl'    # The remote host
PORT = 50007              # The same port as used by the server
s = None
for res in socket.getaddrinfo(HOST, PORT, socket.AF_UNSPEC, socket.SOCK_STREAM):
    af, socktype, proto, canonname, sa = res
    try:
        s = socket.socket(af, socktype, proto)
    except OSError as msg:
        s = None
        continue
    try:
        s.connect(sa)
    except OSError as msg:
        s.close()
        s = None
        continue
    break
if s is None:
    print('could not open socket')
    sys.exit(1)
with s:
    s.sendall(b'Hello, world')
    data = s.recv(1024)
print('Received', repr(data))
```

The next example shows how to write a very simple network sniffer with raw sockets on Windows. The example requires administrator privileges to modify the interface:

```
import socket

# the public network interface
HOST = socket.gethostbyname(socket.gethostname())
```

(continues on next page)

(continued from previous page)

```
# create a raw socket and bind it to the public interface
s = socket.socket(socket.AF_INET, socket.SOCK_RAW, socket.IPPROTO_IP)
s.bind((HOST, 0))

# Include IP headers
s.setsockopt(socket.IPPROTO_IP, socket.IP_HDRINCL, 1)

# receive all packages
s.ioctl(socket.SIO_RCVALL, socket.RCVALL_ON)

# receive a package
print(s.recvfrom(65565))

# disabled promiscuous mode
s.ioctl(socket.SIO_RCVALL, socket.RCVALL_OFF)
```

The next example shows how to use the socket interface to communicate to a CAN network using the raw socket protocol. To use CAN with the broadcast manager protocol instead, open a socket with:

```
socket.socket(socket.AF_CAN, socket.SOCK_DGRAM, socket.CAN_BCM)
```

After binding (`CAN_RAW`) or connecting (*CAN_BCM*) the socket, you can use the *socket.send()*, and the *socket.recv()* operations (and their counterparts) on the socket object as usual.

This last example might require special privileges:

```
import socket
import struct

# CAN frame packing/unpacking (see 'struct can_frame' in <linux/can.h>)

can_frame_fmt = "=IB3x8s"
can_frame_size = struct.calcsize(can_frame_fmt)

def build_can_frame(can_id, data):
    can_dlc = len(data)
    data = data.ljust(8, b'\x00')
    return struct.pack(can_frame_fmt, can_id, can_dlc, data)

def dissect_can_frame(frame):
    can_id, can_dlc, data = struct.unpack(can_frame_fmt, frame)
    return (can_id, can_dlc, data[:can_dlc])

# create a raw socket and bind it to the 'vcan0' interface
s = socket.socket(socket.AF_CAN, socket.SOCK_RAW, socket.CAN_RAW)
s.bind(('vcan0',))

while True:
    cf, addr = s.recvfrom(can_frame_size)

    print('Received: can_id=%x, can_dlc=%x, data=%s' % dissect_can_frame(cf))

    try:
        s.send(cf)
```

(continues on next page)

(continued from previous page)

```
    except OSError:
        print('Error sending CAN frame')

    try:
        s.send(build_can_frame(0x01, b'\x01\x02\x03'))
    except OSError:
        print('Error sending CAN frame')
```

Running an example several times with too small delay between executions, could lead to this error:

```
OSError: [Errno 98] Address already in use
```

This is because the previous execution has left the socket in a `TIME_WAIT` state, and can't be immediately reused.

There is a *socket* flag to set, in order to prevent this, `socket.SO_REUSEADDR`:

```
s = socket.socket(socket.AF_INET, socket.SOCK_STREAM)
s.setsockopt(socket.SOL_SOCKET, socket.SO_REUSEADDR, 1)
s.bind((HOST, PORT))
```

the `SO_REUSEADDR` flag tells the kernel to reuse a local socket in `TIME_WAIT` state, without waiting for its natural timeout to expire.

See also:

For an introduction to socket programming (in C), see the following papers:

- *An Introductory 4.3BSD Interprocess Communication Tutorial*, by Stuart Sechrest
- *An Advanced 4.3BSD Interprocess Communication Tutorial*, by Samuel J. Leffler et al,

both in the UNIX Programmer's Manual, Supplementary Documents 1 (sections PS1:7 and PS1:8). The platform-specific reference material for the various socket-related system calls are also a valuable source of information on the details of socket semantics. For Unix, refer to the manual pages; for Windows, see the WinSock (or Winsock 2) specification. For IPv6-ready APIs, readers may want to refer to **RFC 3493** titled Basic Socket Interface Extensions for IPv6.

19.2 `ssl` — TLS/SSL wrapper for socket objects

Source code: Lib/ssl.py

This module provides access to Transport Layer Security (often known as "Secure Sockets Layer") encryption and peer authentication facilities for network sockets, both client-side and server-side. This module uses the OpenSSL library. It is available on all modern Unix systems, Windows, Mac OS X, and probably additional platforms, as long as OpenSSL is installed on that platform.

Note: Some behavior may be platform dependent, since calls are made to the operating system socket APIs. The installed version of OpenSSL may also cause variations in behavior. For example, TLSv1.1 and TLSv1.2 come with openssl version 1.0.1.

Warning: Don't use this module without reading the *Security considerations*. Doing so may lead to a false sense of security, as the default settings of the ssl module are not necessarily appropriate for your application.

This section documents the objects and functions in the `ssl` module; for more general information about TLS, SSL, and certificates, the reader is referred to the documents in the "See Also" section at the bottom.

This module provides a class, *ssl.SSLSocket*, which is derived from the *socket.socket* type, and provides a socket-like wrapper that also encrypts and decrypts the data going over the socket with SSL. It supports additional methods such as `getpeercert()`, which retrieves the certificate of the other side of the connection, and `cipher()`,which retrieves the cipher being used for the secure connection.

For more sophisticated applications, the *ssl.SSLContext* class helps manage settings and certificates, which can then be inherited by SSL sockets created through the *SSLContext.wrap_socket()* method.

Changed in version 3.5.3: Updated to support linking with OpenSSL 1.1.0

Changed in version 3.6: OpenSSL 0.9.8, 1.0.0 and 1.0.1 are deprecated and no longer supported. In the future the ssl module will require at least OpenSSL 1.0.2 or 1.1.0.

19.2.1 Functions, Constants, and Exceptions

Socket creation

Since Python 3.2 and 2.7.9, it is recommended to use the *SSLContext.wrap_socket()* of an *SSLContext* instance to wrap sockets as *SSLSocket* objects. The helper functions *create_default_context()* returns a new context with secure default settings. The old *wrap_socket()* function is deprecated since it is both inefficient and has no support for server name indication (SNI) and hostname matching.

Client socket example with default context and IPv4/IPv6 dual stack:

```
import socket
import ssl

hostname = 'www.python.org'
context = ssl.create_default_context()

with socket.create_connection((hostname, 443)) as sock:
    with context.wrap_socket(sock, server_hostname=hostname) as ssock:
        print(ssock.version())
```

Client socket example with custom context and IPv4:

```
hostname = 'www.python.org'
# PROTOCOL_TLS_CLIENT requires valid cert chain and hostname
context = ssl.SSLContext(ssl.PROTOCOL_TLS_CLIENT)
context.load_verify_locations('path/to/cabundle.pem')

with socket.socket(socket.AF_INET, socket.SOCK_STREAM, 0) as sock:
    with context.wrap_socket(sock, server_hostname=hostname) as ssock:
        print(ssock.version())
```

Server socket example listening on localhost IPv4:

```
context = ssl.SSLContext(ssl.PROTOCOL_TLS_SERVER)
context.load_cert_chain('/path/to/certchain.pem', '/path/to/private.key')
```

(continues on next page)

(continued from previous page)

```
with socket.socket(socket.AF_INET, socket.SOCK_STREAM, 0) as sock:
    sock.bind(('127.0.0.1', 8443))
    sock.listen(5)
    with context.wrap_socket(sock, server_side=True) as ssock:
        conn, addr = ssock.accept()
        ...
```

Context creation

A convenience function helps create *SSLContext* objects for common purposes.

ssl.create_default_context(*purpose=Purpose.SERVER_AUTH*, *cafile=None*, *capath=None*, *cadata=None*)

Return a new *SSLContext* object with default settings for the given *purpose*. The settings are chosen by the *ssl* module, and usually represent a higher security level than when calling the *SSLContext* constructor directly.

cafile, *capath*, *cadata* represent optional CA certificates to trust for certificate verification, as in *SSLContext.load_verify_locations()*. If all three are *None*, this function can choose to trust the system's default CA certificates instead.

The settings are: *PROTOCOL_TLS*, *OP_NO_SSLv2*, and *OP_NO_SSLv3* with high encryption cipher suites without RC4 and without unauthenticated cipher suites. Passing *SERVER_AUTH* as *purpose* sets *verify_mode* to *CERT_REQUIRED* and either loads CA certificates (when at least one of *cafile*, *capath* or *cadata* is given) or uses *SSLContext.load_default_certs()* to load default CA certificates.

Note: The protocol, options, cipher and other settings may change to more restrictive values anytime without prior deprecation. The values represent a fair balance between compatibility and security.

If your application needs specific settings, you should create a *SSLContext* and apply the settings yourself.

Note: If you find that when certain older clients or servers attempt to connect with a *SSLContext* created by this function that they get an error stating "Protocol or cipher suite mismatch", it may be that they only support SSL3.0 which this function excludes using the *OP_NO_SSLv3*. SSL3.0 is widely considered to be completely broken. If you still wish to continue to use this function but still allow SSL 3.0 connections you can re-enable them using:

```
ctx = ssl.create_default_context(Purpose.CLIENT_AUTH)
ctx.options &= ~ssl.OP_NO_SSLv3
```

New in version 3.4.

Changed in version 3.4.4: RC4 was dropped from the default cipher string.

Changed in version 3.6: ChaCha20/Poly1305 was added to the default cipher string.

3DES was dropped from the default cipher string.

Exceptions

exception ssl.SSLError

Raised to signal an error from the underlying SSL implementation (currently provided by the OpenSSL

library). This signifies some problem in the higher-level encryption and authentication layer that's superimposed on the underlying network connection. This error is a subtype of *OSError*. The error code and message of *SSLError* instances are provided by the OpenSSL library.

Changed in version 3.3: *SSLError* used to be a subtype of *socket.error*.

library
A string mnemonic designating the OpenSSL submodule in which the error occurred, such as `SSL`, `PEM` or `X509`. The range of possible values depends on the OpenSSL version.

New in version 3.3.

reason
A string mnemonic designating the reason this error occurred, for example `CERTIFICATE_VERIFY_FAILED`. The range of possible values depends on the OpenSSL version.

New in version 3.3.

exception ssl.SSLZeroReturnError
A subclass of *SSLError* raised when trying to read or write and the SSL connection has been closed cleanly. Note that this doesn't mean that the underlying transport (read TCP) has been closed.

New in version 3.3.

exception ssl.SSLWantReadError
A subclass of *SSLError* raised by a *non-blocking SSL socket* when trying to read or write data, but more data needs to be received on the underlying TCP transport before the request can be fulfilled.

New in version 3.3.

exception ssl.SSLWantWriteError
A subclass of *SSLError* raised by a *non-blocking SSL socket* when trying to read or write data, but more data needs to be sent on the underlying TCP transport before the request can be fulfilled.

New in version 3.3.

exception ssl.SSLSyscallError
A subclass of *SSLError* raised when a system error was encountered while trying to fulfill an operation on a SSL socket. Unfortunately, there is no easy way to inspect the original errno number.

New in version 3.3.

exception ssl.SSLEOFError
A subclass of *SSLError* raised when the SSL connection has been terminated abruptly. Generally, you shouldn't try to reuse the underlying transport when this error is encountered.

New in version 3.3.

exception ssl.SSLCertVerificationError
A subclass of *SSLError* raised when certificate validation has failed.

New in version 3.7.

verify_code
A numeric error number that denotes the verification error.

verify_message
A human readable string of the verification error.

exception ssl.CertificateError
An alias for *SSLCertVerificationError*.

Changed in version 3.7: The exception is now an alias for *SSLCertVerificationError*.

Random generation

ssl.RAND_bytes(*num*)
: Return *num* cryptographically strong pseudo-random bytes. Raises an *SSLError* if the PRNG has not been seeded with enough data or if the operation is not supported by the current RAND method. *RAND_status()* can be used to check the status of the PRNG and *RAND_add()* can be used to seed the PRNG.

  For almost all applications *os.urandom()* is preferable.

  Read the Wikipedia article, Cryptographically secure pseudorandom number generator (CSPRNG), to get the requirements of a cryptographically generator.

  New in version 3.3.

ssl.RAND_pseudo_bytes(*num*)
: Return (bytes, is_cryptographic): bytes are *num* pseudo-random bytes, is_cryptographic is `True` if the bytes generated are cryptographically strong. Raises an *SSLError* if the operation is not supported by the current RAND method.

  Generated pseudo-random byte sequences will be unique if they are of sufficient length, but are not necessarily unpredictable. They can be used for non-cryptographic purposes and for certain purposes in cryptographic protocols, but usually not for key generation etc.

  For almost all applications *os.urandom()* is preferable.

  New in version 3.3.

  Deprecated since version 3.6: OpenSSL has deprecated *ssl.RAND_pseudo_bytes()*, use *ssl.RAND_bytes()* instead.

ssl.RAND_status()
: Return `True` if the SSL pseudo-random number generator has been seeded with 'enough' randomness, and `False` otherwise. You can use *ssl.RAND_egd()* and *ssl.RAND_add()* to increase the randomness of the pseudo-random number generator.

ssl.RAND_egd(*path*)
: If you are running an entropy-gathering daemon (EGD) somewhere, and *path* is the pathname of a socket connection open to it, this will read 256 bytes of randomness from the socket, and add it to the SSL pseudo-random number generator to increase the security of generated secret keys. This is typically only necessary on systems without better sources of randomness.

  See http://egd.sourceforge.net/ or http://prngd.sourceforge.net/ for sources of entropy-gathering daemons.

  Availability: not available with LibreSSL and OpenSSL > 1.1.0

ssl.RAND_add(*bytes*, *entropy*)
: Mix the given *bytes* into the SSL pseudo-random number generator. The parameter *entropy* (a float) is a lower bound on the entropy contained in string (so you can always use `0.0`). See **RFC 1750** for more information on sources of entropy.

  Changed in version 3.5: Writable *bytes-like object* is now accepted.

Certificate handling

ssl.match_hostname(*cert*, *hostname*)
: Verify that *cert* (in decoded format as returned by *SSLSocket.getpeercert()*) matches the given *hostname*. The rules applied are those for checking the identity of HTTPS servers as outlined in **RFC 2818**, **RFC 5280** and **RFC 6125**. In addition to HTTPS, this function should be suitable for checking the identity of servers in various SSL-based protocols such as FTPS, IMAPS, POPS and others.

CertificateError is raised on failure. On success, the function returns nothing:

```
>>> cert = {'subject': ((('commonName', 'example.com'),),)}
>>> ssl.match_hostname(cert, "example.com")
>>> ssl.match_hostname(cert, "example.org")
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "/home/py3k/Lib/ssl.py", line 130, in match_hostname
ssl.CertificateError: hostname 'example.org' doesn't match 'example.com'
```

New in version 3.2.

Changed in version 3.3.3: The function now follows **RFC 6125**, section 6.4.3 and does neither match multiple wildcards (e.g. `*.*.com` or `*a*.example.org`) nor a wildcard inside an internationalized domain names (IDN) fragment. IDN A-labels such as `www*.xn--pthon-kva.org` are still supported, but `x*.python.org` no longer matches `xn--tda.python.org`.

Changed in version 3.5: Matching of IP addresses, when present in the subjectAltName field of the certificate, is now supported.

Changed in version 3.7: The function is no longer used to TLS connections. Hostname matching is now performed by OpenSSL.

Allow wildcard when it is the leftmost and the only character in that segment. Partial wildcards like `www*.example.com` are no longer supported.

Deprecated since version 3.7.

ssl.cert_time_to_seconds(*cert_time*)

Return the time in seconds since the Epoch, given the `cert_time` string representing the "notBefore" or "notAfter" date from a certificate in `"%b %d %H:%M:%S %Y %Z"` strptime format (C locale).

Here's an example:

```
>>> import ssl
>>> timestamp = ssl.cert_time_to_seconds("Jan  5 09:34:43 2018 GMT")
>>> timestamp
1515144883
>>> from datetime import datetime
>>> print(datetime.utcfromtimestamp(timestamp))
2018-01-05 09:34:43
```

"notBefore" or "notAfter" dates must use GMT (**RFC 5280**).

Changed in version 3.5: Interpret the input time as a time in UTC as specified by 'GMT' timezone in the input string. Local timezone was used previously. Return an integer (no fractions of a second in the input format)

ssl.get_server_certificate(*addr*, *ssl_version=PROTOCOL_TLS*, *ca_certs=None*)

Given the address `addr` of an SSL-protected server, as a (*hostname*, *port-number*) pair, fetches the server's certificate, and returns it as a PEM-encoded string. If `ssl_version` is specified, uses that version of the SSL protocol to attempt to connect to the server. If `ca_certs` is specified, it should be a file containing a list of root certificates, the same format as used for the same parameter in *SSLContext.wrap_socket()*. The call will attempt to validate the server certificate against that set of root certificates, and will fail if the validation attempt fails.

Changed in version 3.3: This function is now IPv6-compatible.

Changed in version 3.5: The default *ssl_version* is changed from *PROTOCOL_SSLv3* to *PROTOCOL_TLS* for maximum compatibility with modern servers.

ssl.DER_cert_to_PEM_cert(*DER_cert_bytes*)
Given a certificate as a DER-encoded blob of bytes, returns a PEM-encoded string version of the same certificate.

ssl.PEM_cert_to_DER_cert(*PEM_cert_string*)
Given a certificate as an ASCII PEM string, returns a DER-encoded sequence of bytes for that same certificate.

ssl.get_default_verify_paths()
Returns a named tuple with paths to OpenSSL's default cafile and capath. The paths are the same as used by *SSLContext.set_default_verify_paths()*. The return value is a *named tuple* `DefaultVerifyPaths`:

- `cafile` - resolved path to cafile or `None` if the file doesn't exist,
- `capath` - resolved path to capath or `None` if the directory doesn't exist,
- `openssl_cafile_env` - OpenSSL's environment key that points to a cafile,
- `openssl_cafile` - hard coded path to a cafile,
- `openssl_capath_env` - OpenSSL's environment key that points to a capath,
- `openssl_capath` - hard coded path to a capath directory

Availability: LibreSSL ignores the environment vars `openssl_cafile_env` and `openssl_capath_env`

New in version 3.4.

ssl.enum_certificates(*store_name*)
Retrieve certificates from Windows' system cert store. *store_name* may be one of `CA`, `ROOT` or `MY`. Windows may provide additional cert stores, too.

The function returns a list of (cert_bytes, encoding_type, trust) tuples. The encoding_type specifies the encoding of cert_bytes. It is either `x509_asn` for X.509 ASN.1 data or `pkcs_7_asn` for PKCS#7 ASN.1 data. Trust specifies the purpose of the certificate as a set of OIDS or exactly `True` if the certificate is trustworthy for all purposes.

Example:

```
>>> ssl.enum_certificates("CA")
[(b'data...', 'x509_asn', {'1.3.6.1.5.5.7.3.1', '1.3.6.1.5.5.7.3.2'}),
 (b'data...', 'x509_asn', True)]
```

Availability: Windows.

New in version 3.4.

ssl.enum_crls(*store_name*)
Retrieve CRLs from Windows' system cert store. *store_name* may be one of `CA`, `ROOT` or `MY`. Windows may provide additional cert stores, too.

The function returns a list of (cert_bytes, encoding_type, trust) tuples. The encoding_type specifies the encoding of cert_bytes. It is either `x509_asn` for X.509 ASN.1 data or `pkcs_7_asn` for PKCS#7 ASN.1 data.

Availability: Windows.

New in version 3.4.

ssl.wrap_socket(*sock*, *keyfile=None*, *certfile=None*, *server_side=False*, *cert_reqs=CERT_NONE*, *ssl_version=PROTOCOL_TLS*, *ca_certs=None*, *do_handshake_on_connect=True*, *suppress_ragged_eofs=True*, *ciphers=None*)
Takes an instance `sock` of *socket.socket*, and returns an instance of *ssl.SSLSocket*, a subtype of *socket.socket*, which wraps the underlying socket in an SSL context. `sock` must be a *SOCK_STREAM* socket; other socket types are unsupported.

Internally, function creates a *SSLContext* with protocol *ssl_version* and *SSLContext.options* set to *cert_reqs*. If parameters *keyfile*, *certfile*, *ca_certs* or *ciphers* are set, then the values are passed to *SSLContext.load_cert_chain()*, *SSLContext.load_verify_locations()*, and *SSLContext.set_ciphers()*.

The arguments *server_side*, *do_handshake_on_connect*, and *suppress_ragged_eofs* have the same meaning as *SSLContext.wrap_socket()*.

Deprecated since version 3.7: Since Python 3.2 and 2.7.9, it is recommended to use the *SSLContext.wrap_socket()* instead of *wrap_socket()*. The top-level function is limited and creates an insecure client socket without server name indication or hostname matching.

Constants

All constants are now *enum.IntEnum* or *enum.IntFlag* collections.

New in version 3.6.

ssl.CERT_NONE

Possible value for *SSLContext.verify_mode*, or the `cert_reqs` parameter to *wrap_socket()*. Except for *PROTOCOL_TLS_CLIENT*, it is the default mode. With client-side sockets, just about any cert is accepted. Validation errors, such as untrusted or expired cert, are ignored and do not abort the TLS/SSL handshake.

In server mode, no certificate is requested from the client, so the client does not send any for client cert authentication.

See the discussion of *Security considerations* below.

ssl.CERT_OPTIONAL

Possible value for *SSLContext.verify_mode*, or the `cert_reqs` parameter to *wrap_socket()*. In client mode, *CERT_OPTIONAL* has the same meaning as *CERT_REQUIRED*. It is recommended to use *CERT_REQUIRED* for client-side sockets instead.

In server mode, a client certificate request is sent to the client. The client may either ignore the request or send a certificate in order perform TLS client cert authentication. If the client chooses to send a certificate, it is verified. Any verification error immediately aborts the TLS handshake.

Use of this setting requires a valid set of CA certificates to be passed, either to *SSLContext.load_verify_locations()* or as a value of the `ca_certs` parameter to *wrap_socket()*.

ssl.CERT_REQUIRED

Possible value for *SSLContext.verify_mode*, or the `cert_reqs` parameter to *wrap_socket()*. In this mode, certificates are required from the other side of the socket connection; an *SSLError* will be raised if no certificate is provided, or if its validation fails. This mode is **not** sufficient to verify a certificate in client mode as it does not match hostnames. *check_hostname* must be enabled as well to verify the authenticity of a cert. *PROTOCOL_TLS_CLIENT* uses *CERT_REQUIRED* and enables *check_hostname* by default.

With server socket, this mode provides mandatory TLS client cert authentication. A client certificate request is sent to the client and the client must provide a valid and trusted certificate.

Use of this setting requires a valid set of CA certificates to be passed, either to *SSLContext.load_verify_locations()* or as a value of the `ca_certs` parameter to *wrap_socket()*.

class ssl.VerifyMode

enum.IntEnum collection of CERT_* constants.

New in version 3.6.

ssl.VERIFY_DEFAULT
Possible value for *SSLContext.verify_flags*. In this mode, certificate revocation lists (CRLs) are not checked. By default OpenSSL does neither require nor verify CRLs.

New in version 3.4.

ssl.VERIFY_CRL_CHECK_LEAF
Possible value for *SSLContext.verify_flags*. In this mode, only the peer cert is check but non of the intermediate CA certificates. The mode requires a valid CRL that is signed by the peer cert's issuer (its direct ancestor CA). If no proper has been loaded *SSLContext.load_verify_locations*, validation will fail.

New in version 3.4.

ssl.VERIFY_CRL_CHECK_CHAIN
Possible value for *SSLContext.verify_flags*. In this mode, CRLs of all certificates in the peer cert chain are checked.

New in version 3.4.

ssl.VERIFY_X509_STRICT
Possible value for *SSLContext.verify_flags* to disable workarounds for broken X.509 certificates.

New in version 3.4.

ssl.VERIFY_X509_TRUSTED_FIRST
Possible value for *SSLContext.verify_flags*. It instructs OpenSSL to prefer trusted certificates when building the trust chain to validate a certificate. This flag is enabled by default.

New in version 3.4.4.

class ssl.VerifyFlags
enum.IntFlag collection of VERIFY_* constants.

New in version 3.6.

ssl.PROTOCOL_TLS
Selects the highest protocol version that both the client and server support. Despite the name, this option can select both "SSL" and "TLS" protocols.

New in version 3.6.

ssl.PROTOCOL_TLS_CLIENT
Auto-negotiate the highest protocol version like *PROTOCOL_TLS*, but only support client-side *SSLSocket* connections. The protocol enables *CERT_REQUIRED* and *check_hostname* by default.

New in version 3.6.

ssl.PROTOCOL_TLS_SERVER
Auto-negotiate the highest protocol version like *PROTOCOL_TLS*, but only support server-side *SSLSocket* connections.

New in version 3.6.

ssl.PROTOCOL_SSLv23
Alias for data:*PROTOCOL_TLS*.

Deprecated since version 3.6: Use *PROTOCOL_TLS* instead.

ssl.PROTOCOL_SSLv2
Selects SSL version 2 as the channel encryption protocol.

This protocol is not available if OpenSSL is compiled with the `OPENSSL_NO_SSL2` flag.

> **Warning:** SSL version 2 is insecure. Its use is highly discouraged.

Deprecated since version 3.6: OpenSSL has removed support for SSLv2.

`ssl.PROTOCOL_SSLv3`
Selects SSL version 3 as the channel encryption protocol.

This protocol is not be available if OpenSSL is compiled with the `OPENSSL_NO_SSLv3` flag.

> **Warning:** SSL version 3 is insecure. Its use is highly discouraged.

Deprecated since version 3.6: OpenSSL has deprecated all version specific protocols. Use the default protocol *PROTOCOL_TLS* with flags like *OP_NO_SSLv3* instead.

`ssl.PROTOCOL_TLSv1`
Selects TLS version 1.0 as the channel encryption protocol.

Deprecated since version 3.6: OpenSSL has deprecated all version specific protocols. Use the default protocol *PROTOCOL_TLS* with flags like *OP_NO_SSLv3* instead.

`ssl.PROTOCOL_TLSv1_1`
Selects TLS version 1.1 as the channel encryption protocol. Available only with openssl version 1.0.1+.

New in version 3.4.

Deprecated since version 3.6: OpenSSL has deprecated all version specific protocols. Use the default protocol *PROTOCOL_TLS* with flags like *OP_NO_SSLv3* instead.

`ssl.PROTOCOL_TLSv1_2`
Selects TLS version 1.2 as the channel encryption protocol. This is the most modern version, and probably the best choice for maximum protection, if both sides can speak it. Available only with openssl version 1.0.1+.

New in version 3.4.

Deprecated since version 3.6: OpenSSL has deprecated all version specific protocols. Use the default protocol *PROTOCOL_TLS* with flags like *OP_NO_SSLv3* instead.

`ssl.OP_ALL`
Enables workarounds for various bugs present in other SSL implementations. This option is set by default. It does not necessarily set the same flags as OpenSSL's `SSL_OP_ALL` constant.

New in version 3.2.

`ssl.OP_NO_SSLv2`
Prevents an SSLv2 connection. This option is only applicable in conjunction with *PROTOCOL_TLS*. It prevents the peers from choosing SSLv2 as the protocol version.

New in version 3.2.

Deprecated since version 3.6: SSLv2 is deprecated

`ssl.OP_NO_SSLv3`
Prevents an SSLv3 connection. This option is only applicable in conjunction with *PROTOCOL_TLS*. It prevents the peers from choosing SSLv3 as the protocol version.

New in version 3.2.

Deprecated since version 3.6: SSLv3 is deprecated

ssl.OP_NO_TLSv1
Prevents a TLSv1 connection. This option is only applicable in conjunction with *PROTOCOL_TLS*. It prevents the peers from choosing TLSv1 as the protocol version.

New in version 3.2.

Deprecated since version 3.7: The option is deprecated since OpenSSL 1.1.0, use the new *SSLContext.minimum_version* and *SSLContext.maximum_version* instead.

ssl.OP_NO_TLSv1_1
Prevents a TLSv1.1 connection. This option is only applicable in conjunction with *PROTOCOL_TLS*. It prevents the peers from choosing TLSv1.1 as the protocol version. Available only with openssl version 1.0.1+.

New in version 3.4.

Deprecated since version 3.7: The option is deprecated since OpenSSL 1.1.0.

ssl.OP_NO_TLSv1_2
Prevents a TLSv1.2 connection. This option is only applicable in conjunction with *PROTOCOL_TLS*. It prevents the peers from choosing TLSv1.2 as the protocol version. Available only with openssl version 1.0.1+.

New in version 3.4.

Deprecated since version 3.7: The option is deprecated since OpenSSL 1.1.0.

ssl.OP_NO_TLSv1_3
Prevents a TLSv1.3 connection. This option is only applicable in conjunction with *PROTOCOL_TLS*. It prevents the peers from choosing TLSv1.3 as the protocol version. TLS 1.3 is available with OpenSSL 1.1.1 or later. When Python has been compiled against an older version of OpenSSL, the flag defaults to *0*.

New in version 3.7.

Deprecated since version 3.7: The option is deprecated since OpenSSL 1.1.0. It was added to 2.7.15, 3.6.3 and 3.7.0 for backwards compatibility with OpenSSL 1.0.2.

ssl.OP_NO_RENEGOTIATION
Disable all renegotiation in TLSv1.2 and earlier. Do not send HelloRequest messages, and ignore renegotiation requests via ClientHello.

This option is only available with OpenSSL 1.1.0h and later.

New in version 3.7.

ssl.OP_CIPHER_SERVER_PREFERENCE
Use the server's cipher ordering preference, rather than the client's. This option has no effect on client sockets and SSLv2 server sockets.

New in version 3.3.

ssl.OP_SINGLE_DH_USE
Prevents re-use of the same DH key for distinct SSL sessions. This improves forward secrecy but requires more computational resources. This option only applies to server sockets.

New in version 3.3.

ssl.OP_SINGLE_ECDH_USE
Prevents re-use of the same ECDH key for distinct SSL sessions. This improves forward secrecy but requires more computational resources. This option only applies to server sockets.

New in version 3.3.

ssl.OP_ENABLE_MIDDLEBOX_COMPAT
Send dummy Change Cipher Spec (CCS) messages in TLS 1.3 handshake to make a TLS 1.3 connection look more like a TLS 1.2 connection.

This option is only available with OpenSSL 1.1.1 and later.

New in version 3.8.

ssl.OP_NO_COMPRESSION
Disable compression on the SSL channel. This is useful if the application protocol supports its own compression scheme.

This option is only available with OpenSSL 1.0.0 and later.

New in version 3.3.

class ssl.Options
enum.IntFlag collection of OP_* constants.

ssl.OP_NO_TICKET
Prevent client side from requesting a session ticket.

New in version 3.6.

ssl.HAS_ALPN
Whether the OpenSSL library has built-in support for the *Application-Layer Protocol Negotiation* TLS extension as described in **RFC 7301**.

New in version 3.5.

ssl.HAS_NEVER_CHECK_COMMON_NAME
Whether the OpenSSL library has built-in support not checking subject common name and *SSLContext.hostname_checks_common_name* is writeable.

New in version 3.7.

ssl.HAS_ECDH
Whether the OpenSSL library has built-in support for the Elliptic Curve-based Diffie-Hellman key exchange. This should be true unless the feature was explicitly disabled by the distributor.

New in version 3.3.

ssl.HAS_SNI
Whether the OpenSSL library has built-in support for the *Server Name Indication* extension (as defined in **RFC 6066**).

New in version 3.2.

ssl.HAS_NPN
Whether the OpenSSL library has built-in support for the *Next Protocol Negotiation* as described in the Application Layer Protocol Negotiation. When true, you can use the *SSLContext.set_npn_protocols()* method to advertise which protocols you want to support.

New in version 3.3.

ssl.HAS_SSLv2
Whether the OpenSSL library has built-in support for the SSL 2.0 protocol.

New in version 3.7.

ssl.HAS_SSLv3
Whether the OpenSSL library has built-in support for the SSL 3.0 protocol.

New in version 3.7.

ssl.HAS_TLSv1
Whether the OpenSSL library has built-in support for the TLS 1.0 protocol.

New in version 3.7.

ssl.HAS_TLSv1_1
Whether the OpenSSL library has built-in support for the TLS 1.1 protocol.

New in version 3.7.

ssl.HAS_TLSv1_2
Whether the OpenSSL library has built-in support for the TLS 1.2 protocol.

New in version 3.7.

ssl.HAS_TLSv1_3
Whether the OpenSSL library has built-in support for the TLS 1.3 protocol.

New in version 3.7.

ssl.CHANNEL_BINDING_TYPES
List of supported TLS channel binding types. Strings in this list can be used as arguments to *SSLSocket.get_channel_binding()*.

New in version 3.3.

ssl.OPENSSL_VERSION
The version string of the OpenSSL library loaded by the interpreter:

```
>>> ssl.OPENSSL_VERSION
'OpenSSL 1.0.2k  26 Jan 2017'
```

New in version 3.2.

ssl.OPENSSL_VERSION_INFO
A tuple of five integers representing version information about the OpenSSL library:

```
>>> ssl.OPENSSL_VERSION_INFO
(1, 0, 2, 11, 15)
```

New in version 3.2.

ssl.OPENSSL_VERSION_NUMBER
The raw version number of the OpenSSL library, as a single integer:

```
>>> ssl.OPENSSL_VERSION_NUMBER
268443839
>>> hex(ssl.OPENSSL_VERSION_NUMBER)
'0x100020bf'
```

New in version 3.2.

ssl.ALERT_DESCRIPTION_HANDSHAKE_FAILURE
ssl.ALERT_DESCRIPTION_INTERNAL_ERROR
ALERT_DESCRIPTION_*
Alert Descriptions from **RFC 5246** and others. The IANA TLS Alert Registry contains this list and references to the RFCs where their meaning is defined.

Used as the return value of the callback function in *SSLContext.set_servername_callback()*.

New in version 3.4.

class ssl.AlertDescription
enum.IntEnum collection of ALERT_DESCRIPTION_* constants.

New in version 3.6.

Purpose.**SERVER_AUTH**
Option for *create_default_context()* and *SSLContext.load_default_certs()*. This value indicates that the context may be used to authenticate Web servers (therefore, it will be used to create client-side sockets).

New in version 3.4.

Purpose.**CLIENT_AUTH**
Option for *create_default_context()* and *SSLContext.load_default_certs()*. This value indicates that the context may be used to authenticate Web clients (therefore, it will be used to create server-side sockets).

New in version 3.4.

class ssl.SSLErrorNumber
enum.IntEnum collection of SSL_ERROR_* constants.

New in version 3.6.

class ssl.TLSVersion
enum.IntEnum collection of SSL and TLS versions for *SSLContext.maximum_version* and *SSLContext.minimum_version*.

New in version 3.7.

TLSVersion.**MINIMUM_SUPPORTED**

TLSVersion.**MAXIMUM_SUPPORTED**
The minimum or maximum supported SSL or TLS version. These are magic constants. Their values don't reflect the lowest and highest available TLS/SSL versions.

TLSVersion.**SSLv3**

TLSVersion.**TLSv1**

TLSVersion.**TLSv1_1**

TLSVersion.**TLSv1_2**

TLSVersion.**TLSv1_3**
SSL 3.0 to TLS 1.3.

19.2.2 SSL Sockets

class ssl.SSLSocket(*socket.socket*)
SSL sockets provide the following methods of *Socket Objects*:

- *accept()*
- *bind()*
- *close()*
- *connect()*
- *detach()*
- *fileno()*
- *getpeername()*, *getsockname()*
- *getsockopt()*, *setsockopt()*
- *gettimeout()*, *settimeout()*, *setblocking()*
- *listen()*
- *makefile()*

- *recv()*, *recv_into()* (but passing a non-zero `flags` argument is not allowed)
- *send()*, *sendall()* (with the same limitation)
- *sendfile()* (but *os.sendfile* will be used for plain-text sockets only, else *send()* will be used)
- *shutdown()*

However, since the SSL (and TLS) protocol has its own framing atop of TCP, the SSL sockets abstraction can, in certain respects, diverge from the specification of normal, OS-level sockets. See especially the *notes on non-blocking sockets*.

Instances of *SSLSocket* must be created using the *SSLContext.wrap_socket()* method.

Changed in version 3.5: The `sendfile()` method was added.

Changed in version 3.5: The `shutdown()` does not reset the socket timeout each time bytes are received or sent. The socket timeout is now to maximum total duration of the shutdown.

Deprecated since version 3.6: It is deprecated to create a *SSLSocket* instance directly, use *SSLContext.wrap_socket()* to wrap a socket.

Changed in version 3.7: *SSLSocket* instances must to created with *wrap_socket()*. In earlier versions, it was possible to create instances directly. This was never documented or officially supported.

SSL sockets also have the following additional methods and attributes:

`SSLSocket.read`(*len=1024*, *buffer=None*)

Read up to *len* bytes of data from the SSL socket and return the result as a `bytes` instance. If *buffer* is specified, then read into the buffer instead, and return the number of bytes read.

Raise *SSLWantReadError* or *SSLWantWriteError* if the socket is *non-blocking* and the read would block.

As at any time a re-negotiation is possible, a call to *read()* can also cause write operations.

Changed in version 3.5: The socket timeout is no more reset each time bytes are received or sent. The socket timeout is now to maximum total duration to read up to *len* bytes.

Deprecated since version 3.6: Use `recv()` instead of *read()*.

`SSLSocket.write`(*buf*)

Write *buf* to the SSL socket and return the number of bytes written. The *buf* argument must be an object supporting the buffer interface.

Raise *SSLWantReadError* or *SSLWantWriteError* if the socket is *non-blocking* and the write would block.

As at any time a re-negotiation is possible, a call to *write()* can also cause read operations.

Changed in version 3.5: The socket timeout is no more reset each time bytes are received or sent. The socket timeout is now to maximum total duration to write *buf*.

Deprecated since version 3.6: Use `send()` instead of *write()*.

Note: The *read()* and *write()* methods are the low-level methods that read and write unencrypted, application-level data and decrypt/encrypt it to encrypted, wire-level data. These methods require an active SSL connection, i.e. the handshake was completed and *SSLSocket.unwrap()* was not called.

Normally you should use the socket API methods like *recv()* and *send()* instead of these methods.

`SSLSocket.do_handshake`()

Perform the SSL setup handshake.

Changed in version 3.4: The handshake method also performs *match_hostname()* when the *check_hostname* attribute of the socket's *context* is true.

Changed in version 3.5: The socket timeout is no more reset each time bytes are received or sent. The socket timeout is now to maximum total duration of the handshake.

Changed in version 3.7: Hostname or IP address is matched by OpenSSL during handshake. The function *match_hostname()* is no longer used. In case OpenSSL refuses a hostname or IP address, the handshake is aborted early and a TLS alert message is send to the peer.

SSLSocket.**getpeercert**(*binary_form=False*)

If there is no certificate for the peer on the other end of the connection, return `None`. If the SSL handshake hasn't been done yet, raise *ValueError*.

If the `binary_form` parameter is *False*, and a certificate was received from the peer, this method returns a *dict* instance. If the certificate was not validated, the dict is empty. If the certificate was validated, it returns a dict with several keys, amongst them `subject` (the principal for which the certificate was issued) and `issuer` (the principal issuing the certificate). If a certificate contains an instance of the *Subject Alternative Name* extension (see **RFC 3280**), there will also be a `subjectAltName` key in the dictionary.

The `subject` and `issuer` fields are tuples containing the sequence of relative distinguished names (RDNs) given in the certificate's data structure for the respective fields, and each RDN is a sequence of name-value pairs. Here is a real-world example:

```
{'issuer': ((('countryName', 'IL'),),
            ((('organizationName', 'StartCom Ltd.'),),
            ((('organizationalUnitName',
              'Secure Digital Certificate Signing'),),
            ((('commonName',
              'StartCom Class 2 Primary Intermediate Server CA'),)),
 'notAfter': 'Nov 22 08:15:19 2013 GMT',
 'notBefore': 'Nov 21 03:09:52 2011 GMT',
 'serialNumber': '95F0',
 'subject': ((('description', '571208-SLe257oHY9fVQ07Z'),),
             ((('countryName', 'US'),),
             ((('stateOrProvinceName', 'California'),),
             ((('localityName', 'San Francisco'),),
             ((('organizationName', 'Electronic Frontier Foundation, Inc.'),),
             ((('commonName', '*.eff.org'),),
             ((('emailAddress', 'hostmaster@eff.org'),)),
 'subjectAltName': (('DNS', '*.eff.org'), ('DNS', 'eff.org')),
 'version': 3}
```

Note: To validate a certificate for a particular service, you can use the *match_hostname()* function.

If the `binary_form` parameter is *True*, and a certificate was provided, this method returns the DER-encoded form of the entire certificate as a sequence of bytes, or *None* if the peer did not provide a certificate. Whether the peer provides a certificate depends on the SSL socket's role:

- for a client SSL socket, the server will always provide a certificate, regardless of whether validation was required;
- for a server SSL socket, the client will only provide a certificate when requested by the server; therefore *getpeercert()* will return *None* if you used *CERT_NONE* (rather than *CERT_OPTIONAL* or *CERT_REQUIRED*).

Changed in version 3.2: The returned dictionary includes additional items such as `issuer` and `notBefore`.

Changed in version 3.4: *ValueError* is raised when the handshake isn't done. The returned dictionary includes additional X509v3 extension items such as `crlDistributionPoints`, `caIssuers` and `OCSP`

URIs.

SSLSocket.cipher()
Returns a three-value tuple containing the name of the cipher being used, the version of the SSL protocol that defines its use, and the number of secret bits being used. If no connection has been established, returns None.

SSLSocket.shared_ciphers()
Return the list of ciphers shared by the client during the handshake. Each entry of the returned list is a three-value tuple containing the name of the cipher, the version of the SSL protocol that defines its use, and the number of secret bits the cipher uses. *shared_ciphers()* returns None if no connection has been established or the socket is a client socket.

New in version 3.5.

SSLSocket.compression()
Return the compression algorithm being used as a string, or None if the connection isn't compressed.

If the higher-level protocol supports its own compression mechanism, you can use *OP_NO_COMPRESSION* to disable SSL-level compression.

New in version 3.3.

SSLSocket.get_channel_binding(*cb_type="tls-unique"*)
Get channel binding data for current connection, as a bytes object. Returns None if not connected or the handshake has not been completed.

The *cb_type* parameter allow selection of the desired channel binding type. Valid channel binding types are listed in the *CHANNEL_BINDING_TYPES* list. Currently only the 'tls-unique' channel binding, defined by **RFC 5929**, is supported. *ValueError* will be raised if an unsupported channel binding type is requested.

New in version 3.3.

SSLSocket.selected_alpn_protocol()
Return the protocol that was selected during the TLS handshake. If *SSLContext.set_alpn_protocols()* was not called, if the other party does not support ALPN, if this socket does not support any of the client's proposed protocols, or if the handshake has not happened yet, None is returned.

New in version 3.5.

SSLSocket.selected_npn_protocol()
Return the higher-level protocol that was selected during the TLS/SSL handshake. If *SSLContext.set_npn_protocols()* was not called, or if the other party does not support NPN, or if the handshake has not yet happened, this will return None.

New in version 3.3.

SSLSocket.unwrap()
Performs the SSL shutdown handshake, which removes the TLS layer from the underlying socket, and returns the underlying socket object. This can be used to go from encrypted operation over a connection to unencrypted. The returned socket should always be used for further communication with the other side of the connection, rather than the original socket.

SSLSocket.version()
Return the actual SSL protocol version negotiated by the connection as a string, or None is no secure connection is established. As of this writing, possible return values include "SSLv2", "SSLv3", "TLSv1", "TLSv1.1" and "TLSv1.2". Recent OpenSSL versions may define more return values.

New in version 3.5.

SSLSocket.pending()
Returns the number of already decrypted bytes available for read, pending on the connection.

SSLSocket.context
: The *SSLContext* object this SSL socket is tied to. If the SSL socket was created using the deprecated *wrap_socket()* function (rather than *SSLContext.wrap_socket()*), this is a custom context object created for this SSL socket.

  New in version 3.2.

SSLSocket.server_side
: A boolean which is `True` for server-side sockets and `False` for client-side sockets.

  New in version 3.2.

SSLSocket.server_hostname
: Hostname of the server: *str* type, or `None` for server-side socket or if the hostname was not specified in the constructor.

  New in version 3.2.

  Changed in version 3.7: The attribute is now always ASCII text. When `server_hostname` is an internationalized domain name (IDN), this attribute now stores the A-label form (`"xn--pythn-mua.org"`), rather than the U-label form (`"pythön.org"`).

SSLSocket.session
: The *SSLSession* for this SSL connection. The session is available for client and server side sockets after the TLS handshake has been performed. For client sockets the session can be set before *do_handshake()* has been called to reuse a session.

  New in version 3.6.

SSLSocket.session_reused
: New in version 3.6.

19.2.3 SSL Contexts

New in version 3.2.

An SSL context holds various data longer-lived than single SSL connections, such as SSL configuration options, certificate(s) and private key(s). It also manages a cache of SSL sessions for server-side sockets, in order to speed up repeated connections from the same clients.

class ssl.SSLContext(*protocol=PROTOCOL_TLS*)
: Create a new SSL context. You may pass *protocol* which must be one of the `PROTOCOL_*` constants defined in this module. The parameter specifies which version of the SSL protocol to use. Typically, the server chooses a particular protocol version, and the client must adapt to the server's choice. Most of the versions are not interoperable with the other versions. If not specified, the default is *PROTOCOL_TLS*; it provides the most compatibility with other versions.

  Here's a table showing which versions in a client (down the side) can connect to which versions in a server (along the top):

client / **server**	**SSLv2**	**SSLv3**	**TLS**[3]	**TLSv1**	**TLSv1.1**	**TLSv1.2**
SSLv2	yes	no	no[1]	no	no	no
SSLv3	no	yes	no[2]	no	no	no
TLS (SSLv23)[3]	no[1]	no[2]	yes	yes	yes	yes
TLSv1	no	no	yes	yes	no	no
TLSv1.1	no	no	yes	no	yes	no
TLSv1.2	no	no	yes	no	no	yes

See also:

create_default_context() lets the *ssl* module choose security settings for a given purpose.

Changed in version 3.6: The context is created with secure default values. The options *OP_NO_COMPRESSION*, *OP_CIPHER_SERVER_PREFERENCE*, *OP_SINGLE_DH_USE*, *OP_SINGLE_ECDH_USE*, *OP_NO_SSLv2* (except for *PROTOCOL_SSLv2*), and *OP_NO_SSLv3* (except for *PROTOCOL_SSLv3*) are set by default. The initial cipher suite list contains only `HIGH` ciphers, no `NULL` ciphers and no `MD5` ciphers (except for *PROTOCOL_SSLv2*).

SSLContext objects have the following methods and attributes:

SSLContext.cert_store_stats()

Get statistics about quantities of loaded X.509 certificates, count of X.509 certificates flagged as CA certificates and certificate revocation lists as dictionary.

Example for a context with one CA cert and one other cert:

```
>>> context.cert_store_stats()
{'crl': 0, 'x509_ca': 1, 'x509': 2}
```

New in version 3.4.

SSLContext.load_cert_chain(*certfile*, *keyfile=None*, *password=None*)

Load a private key and the corresponding certificate. The *certfile* string must be the path to a single file in PEM format containing the certificate as well as any number of CA certificates needed to establish the certificate's authenticity. The *keyfile* string, if present, must point to a file containing the private key in. Otherwise the private key will be taken from *certfile* as well. See the discussion of *Certificates* for more information on how the certificate is stored in the *certfile*.

The *password* argument may be a function to call to get the password for decrypting the private key. It will only be called if the private key is encrypted and a password is necessary. It will be called with no arguments, and it should return a string, bytes, or bytearray. If the return value is a string it will be encoded as UTF-8 before using it to decrypt the key. Alternatively a string, bytes, or bytearray value may be supplied directly as the *password* argument. It will be ignored if the private key is not encrypted and no password is needed.

If the *password* argument is not specified and a password is required, OpenSSL's built-in password prompting mechanism will be used to interactively prompt the user for a password.

An *SSLError* is raised if the private key doesn't match with the certificate.

Changed in version 3.3: New optional argument *password*.

SSLContext.load_default_certs(*purpose=Purpose.SERVER_AUTH*)

Load a set of default "certification authority" (CA) certificates from default locations. On Windows it loads CA certs from the `CA` and `ROOT` system stores. On other systems it calls *SSLContext.set_default_verify_paths()*. In the future the method may load CA certificates from other locations, too.

The *purpose* flag specifies what kind of CA certificates are loaded. The default settings *Purpose.SERVER_AUTH* loads certificates, that are flagged and trusted for TLS web server authentication (client side sockets). *Purpose.CLIENT_AUTH* loads CA certificates for client certificate verification on the server side.

New in version 3.4.

[3] TLS 1.3 protocol will be available with *PROTOCOL_TLS* in OpenSSL >= 1.1.1. There is no dedicated PROTOCOL constant for just TLS 1.3.

[1] *SSLContext* disables SSLv2 with *OP_NO_SSLv2* by default.

[2] *SSLContext* disables SSLv3 with *OP_NO_SSLv3* by default.

SSLContext.load_verify_locations(*cafile=None*, *capath=None*, *cadata=None*)

Load a set of "certification authority" (CA) certificates used to validate other peers' certificates when *verify_mode* is other than *CERT_NONE*. At least one of *cafile* or *capath* must be specified.

This method can also load certification revocation lists (CRLs) in PEM or DER format. In order to make use of CRLs, *SSLContext.verify_flags* must be configured properly.

The *cafile* string, if present, is the path to a file of concatenated CA certificates in PEM format. See the discussion of *Certificates* for more information about how to arrange the certificates in this file.

The *capath* string, if present, is the path to a directory containing several CA certificates in PEM format, following an OpenSSL specific layout.

The *cadata* object, if present, is either an ASCII string of one or more PEM-encoded certificates or a *bytes-like object* of DER-encoded certificates. Like with *capath* extra lines around PEM-encoded certificates are ignored but at least one certificate must be present.

Changed in version 3.4: New optional argument *cadata*

SSLContext.get_ca_certs(*binary_form=False*)

Get a list of loaded "certification authority" (CA) certificates. If the `binary_form` parameter is *False* each list entry is a dict like the output of *SSLSocket.getpeercert()*. Otherwise the method returns a list of DER-encoded certificates. The returned list does not contain certificates from *capath* unless a certificate was requested and loaded by a SSL connection.

Note: Certificates in a capath directory aren't loaded unless they have been used at least once.

New in version 3.4.

SSLContext.get_ciphers()

Get a list of enabled ciphers. The list is in order of cipher priority. See *SSLContext.set_ciphers()*.

Example:

```
>>> ctx = ssl.SSLContext(ssl.PROTOCOL_SSLv23)
>>> ctx.set_ciphers('ECDHE+AESGCM:!ECDSA')
>>> ctx.get_ciphers()  # OpenSSL 1.0.x
[{'alg_bits': 256,
  'description': 'ECDHE-RSA-AES256-GCM-SHA384 TLSv1.2 Kx=ECDH     Au=RSA  '
                 'Enc=AESGCM(256) Mac=AEAD',
  'id': 50380848,
  'name': 'ECDHE-RSA-AES256-GCM-SHA384',
  'protocol': 'TLSv1/SSLv3',
  'strength_bits': 256},
 {'alg_bits': 128,
  'description': 'ECDHE-RSA-AES128-GCM-SHA256 TLSv1.2 Kx=ECDH     Au=RSA  '
                 'Enc=AESGCM(128) Mac=AEAD',
  'id': 50380847,
  'name': 'ECDHE-RSA-AES128-GCM-SHA256',
  'protocol': 'TLSv1/SSLv3',
  'strength_bits': 128}]
```

On OpenSSL 1.1 and newer the cipher dict contains additional fields:

```
>>> ctx.get_ciphers()  # OpenSSL 1.1+
[{'aead': True,
  'alg_bits': 256,
  'auth': 'auth-rsa',
  'description': 'ECDHE-RSA-AES256-GCM-SHA384 TLSv1.2 Kx=ECDH     Au=RSA  '
```

(continues on next page)

(continued from previous page)

```
                'Enc=AESGCM(256) Mac=AEAD',
  'digest': None,
  'id': 50380848,
  'kea': 'kx-ecdhe',
  'name': 'ECDHE-RSA-AES256-GCM-SHA384',
  'protocol': 'TLSv1.2',
  'strength_bits': 256,
  'symmetric': 'aes-256-gcm'},
 {'aead': True,
  'alg_bits': 128,
  'auth': 'auth-rsa',
  'description': 'ECDHE-RSA-AES128-GCM-SHA256 TLSv1.2 Kx=ECDH     Au=RSA  '
                'Enc=AESGCM(128) Mac=AEAD',
  'digest': None,
  'id': 50380847,
  'kea': 'kx-ecdhe',
  'name': 'ECDHE-RSA-AES128-GCM-SHA256',
  'protocol': 'TLSv1.2',
  'strength_bits': 128,
  'symmetric': 'aes-128-gcm'}]
```

Availability: OpenSSL 1.0.2+

New in version 3.6.

SSLContext.set_default_verify_paths()

Load a set of default "certification authority" (CA) certificates from a filesystem path defined when building the OpenSSL library. Unfortunately, there's no easy way to know whether this method succeeds: no error is returned if no certificates are to be found. When the OpenSSL library is provided as part of the operating system, though, it is likely to be configured properly.

SSLContext.set_ciphers(*ciphers*)

Set the available ciphers for sockets created with this context. It should be a string in the OpenSSL cipher list format. If no cipher can be selected (because compile-time options or other configuration forbids use of all the specified ciphers), an *SSLError* will be raised.

Note: when connected, the *SSLSocket.cipher()* method of SSL sockets will give the currently selected cipher.

OpenSSL 1.1.1 has TLS 1.3 cipher suites enabled by default. The suites cannot be disabled with *set_ciphers()*.

SSLContext.set_alpn_protocols(*protocols*)

Specify which protocols the socket should advertise during the SSL/TLS handshake. It should be a list of ASCII strings, like `['http/1.1', 'spdy/2']`, ordered by preference. The selection of a protocol will happen during the handshake, and will play out according to **RFC 7301**. After a successful handshake, the *SSLSocket.selected_alpn_protocol()* method will return the agreed-upon protocol.

This method will raise *NotImplementedError* if *HAS_ALPN* is False.

OpenSSL 1.1.0 to 1.1.0e will abort the handshake and raise *SSLError* when both sides support ALPN but cannot agree on a protocol. 1.1.0f+ behaves like 1.0.2, *SSLSocket.selected_alpn_protocol()* returns None.

New in version 3.5.

SSLContext.set_npn_protocols(*protocols*)

Specify which protocols the socket should advertise during the SSL/TLS handshake. It should be

a list of strings, like `['http/1.1', 'spdy/2']`, ordered by preference. The selection of a protocol will happen during the handshake, and will play out according to the Application Layer Protocol Negotiation. After a successful handshake, the *SSLSocket.selected_npn_protocol()* method will return the agreed-upon protocol.

This method will raise *NotImplementedError* if *HAS_NPN* is False.

New in version 3.3.

`SSLContext.sni_callback`
Register a callback function that will be called after the TLS Client Hello handshake message has been received by the SSL/TLS server when the TLS client specifies a server name indication. The server name indication mechanism is specified in **RFC 6066** section 3 - Server Name Indication.

Only one callback can be set per `SSLContext`. If *sni_callback* is set to `None` then the callback is disabled. Calling this function a subsequent time will disable the previously registered callback.

The callback function will be called with three arguments; the first being the *ssl.SSLSocket*, the second is a string that represents the server name that the client is intending to communicate (or *None* if the TLS Client Hello does not contain a server name) and the third argument is the original *SSLContext*. The server name argument is text. For internationalized domain name, the server name is an IDN A-label (`"xn--pythn-mua.org"`).

A typical use of this callback is to change the *ssl.SSLSocket*'s *SSLSocket.context* attribute to a new object of type *SSLContext* representing a certificate chain that matches the server name.

Due to the early negotiation phase of the TLS connection, only limited methods and attributes are usable like *SSLSocket.selected_alpn_protocol()* and *SSLSocket.context*. *SSLSocket.getpeercert()*, *SSLSocket.getpeercert()*, *SSLSocket.cipher()* and `SSLSocket.compress()` methods require that the TLS connection has progressed beyond the TLS Client Hello and therefore will not contain return meaningful values nor can they be called safely.

The *sni_callback* function must return `None` to allow the TLS negotiation to continue. If a TLS failure is required, a constant *ALERT_DESCRIPTION_** can be returned. Other return values will result in a TLS fatal error with *ALERT_DESCRIPTION_INTERNAL_ERROR*.

If an exception is raised from the *sni_callback* function the TLS connection will terminate with a fatal TLS alert message *ALERT_DESCRIPTION_HANDSHAKE_FAILURE*.

This method will raise *NotImplementedError* if the OpenSSL library had OPENSSL_NO_TLSEXT defined when it was built.

New in version 3.7.

`SSLContext.set_servername_callback`(*server_name_callback*)
This is a legacy API retained for backwards compatibility. When possible, you should use *sni_callback* instead. The given *server_name_callback* is similar to *sni_callback*, except that when the server hostname is an IDN-encoded internationalized domain name, the *server_name_callback* receives a decoded U-label (`"pythön.org"`).

If there is an decoding error on the server name, the TLS connection will terminate with an *ALERT_DESCRIPTION_INTERNAL_ERROR* fatal TLS alert message to the client.

New in version 3.4.

`SSLContext.load_dh_params`(*dhfile*)
Load the key generation parameters for Diffie-Hellman (DH) key exchange. Using DH key exchange improves forward secrecy at the expense of computational resources (both on the server and on the client). The *dhfile* parameter should be the path to a file containing DH parameters in PEM format.

This setting doesn't apply to client sockets. You can also use the *OP_SINGLE_DH_USE* option to further improve security.

New in version 3.3.

SSLContext.set_ecdh_curve(*curve_name*)
Set the curve name for Elliptic Curve-based Diffie-Hellman (ECDH) key exchange. ECDH is significantly faster than regular DH while arguably as secure. The *curve_name* parameter should be a string describing a well-known elliptic curve, for example `prime256v1` for a widely supported curve.

This setting doesn't apply to client sockets. You can also use the *OP_SINGLE_ECDH_USE* option to further improve security.

This method is not available if *HAS_ECDH* is `False`.

New in version 3.3.

See also:

SSL/TLS & Perfect Forward Secrecy Vincent Bernat.

SSLContext.wrap_socket(*sock*, *server_side=False*, *do_handshake_on_connect=True*, *suppress_ragged_eofs=True*, *server_hostname=None*, *session=None*)
Wrap an existing Python socket *sock* and return an instance of *SSLContext.sslsocket_class* (default *SSLSocket*). The returned SSL socket is tied to the context, its settings and certificates. *sock* must be a *SOCK_STREAM* socket; other socket types are unsupported.

The parameter `server_side` is a boolean which identifies whether server-side or client-side behavior is desired from this socket.

For client-side sockets, the context construction is lazy; if the underlying socket isn't connected yet, the context construction will be performed after `connect()` is called on the socket. For server-side sockets, if the socket has no remote peer, it is assumed to be a listening socket, and the server-side SSL wrapping is automatically performed on client connections accepted via the `accept()` method. The method may raise *SSLError*.

On client connections, the optional parameter *server_hostname* specifies the hostname of the service which we are connecting to. This allows a single server to host multiple SSL-based services with distinct certificates, quite similarly to HTTP virtual hosts. Specifying *server_hostname* will raise a *ValueError* if *server_side* is true.

The parameter `do_handshake_on_connect` specifies whether to do the SSL handshake automatically after doing a `socket.connect()`, or whether the application program will call it explicitly, by invoking the *SSLSocket.do_handshake()* method. Calling *SSLSocket.do_handshake()* explicitly gives the program control over the blocking behavior of the socket I/O involved in the handshake.

The parameter `suppress_ragged_eofs` specifies how the `SSLSocket.recv()` method should signal unexpected EOF from the other end of the connection. If specified as *True* (the default), it returns a normal EOF (an empty bytes object) in response to unexpected EOF errors raised from the underlying socket; if *False*, it will raise the exceptions back to the caller.

session, see *session*.

Changed in version 3.5: Always allow a server_hostname to be passed, even if OpenSSL does not have SNI.

Changed in version 3.6: *session* argument was added.

Changed in version 3.7: The method returns on instance of *SSLContext.sslsocket_class* instead of hard-coded *SSLSocket*.

SSLContext.sslsocket_class
The return type of `SSLContext.wrap_sockets()`, defaults to *SSLSocket*. The attribute can be overridden on instance of class in order to return a custom subclass of *SSLSocket*.

New in version 3.7.

SSLContext.**wrap_bio**(*incoming*, *outgoing*, *server_side=False*, *server_hostname=None*, *session=None*)

Wrap the BIO objects *incoming* and *outgoing* and return an instance of attr:*SSLContext.sslobject_class* (default *SSLObject*). The SSL routines will read input data from the incoming BIO and write data to the outgoing BIO.

The *server_side*, *server_hostname* and *session* parameters have the same meaning as in *SSLContext.wrap_socket()*.

Changed in version 3.6: *session* argument was added.

Changed in version 3.7: The method returns on instance of *SSLContext.sslobject_class* instead of hard-coded *SSLObject*.

SSLContext.**sslobject_class**

The return type of *SSLContext.wrap_bio()*, defaults to *SSLObject*. The attribute can be overridden on instance of class in order to return a custom subclass of *SSLObject*.

New in version 3.7.

SSLContext.**session_stats**()

Get statistics about the SSL sessions created or managed by this context. A dictionary is returned which maps the names of each piece of information to their numeric values. For example, here is the total number of hits and misses in the session cache since the context was created:

```
>>> stats = context.session_stats()
>>> stats['hits'], stats['misses']
(0, 0)
```

SSLContext.**check_hostname**

Whether to match the peer cert's hostname with *match_hostname()* in *SSLSocket.do_handshake()*. The context's *verify_mode* must be set to *CERT_OPTIONAL* or *CERT_REQUIRED*, and you must pass *server_hostname* to *wrap_socket()* in order to match the hostname. Enabling hostname checking automatically sets *verify_mode* from *CERT_NONE* to *CERT_REQUIRED*. It cannot be set back to *CERT_NONE* as long as hostname checking is enabled.

Example:

```
import socket, ssl

context = ssl.SSLContext()
context.verify_mode = ssl.CERT_REQUIRED
context.check_hostname = True
context.load_default_certs()

s = socket.socket(socket.AF_INET, socket.SOCK_STREAM)
ssl_sock = context.wrap_socket(s, server_hostname='www.verisign.com')
ssl_sock.connect(('www.verisign.com', 443))
```

New in version 3.4.

Changed in version 3.7: *verify_mode* is now automatically changed to *CERT_REQUIRED* when hostname checking is enabled and *verify_mode* is *CERT_NONE*. Previously the same operation would have failed with a *ValueError*.

Note: This features requires OpenSSL 0.9.8f or newer.

SSLContext.**maximum_version**

A *TLSVersion* enum member representing the highest supported TLS version. The value defaults to

TLSVersion.MAXIMUM_SUPPORTED. The attribute is read-only for protocols other than *PROTOCOL_TLS*, *PROTOCOL_TLS_CLIENT*, and *PROTOCOL_TLS_SERVER*.

The attributes *maximum_version*, *minimum_version* and *SSLContext.options* all affect the supported SSL and TLS versions of the context. The implementation does not prevent invalid combination. For example a context with *OP_NO_TLSv1_2* in *options* and *maximum_version* set to *TLSVersion.TLSv1_2* will not be able to establish a TLS 1.2 connection.

Note: This attribute is not available unless the ssl module is compiled with OpenSSL 1.1.0g or newer.

SSLContext.minimum_version

Like *SSLContext.maximum_version* except it is the lowest supported version or *TLSVersion.MINIMUM_SUPPORTED*.

Note: This attribute is not available unless the ssl module is compiled with OpenSSL 1.1.0g or newer.

SSLContext.options

An integer representing the set of SSL options enabled on this context. The default value is *OP_ALL*, but you can specify other options such as *OP_NO_SSLv2* by ORing them together.

Note: With versions of OpenSSL older than 0.9.8m, it is only possible to set options, not to clear them. Attempting to clear an option (by resetting the corresponding bits) will raise a `ValueError`.

Changed in version 3.6: *SSLContext.options* returns *Options* flags:

```
>>> ssl.create_default_context().options
<Options.OP_ALL|OP_NO_SSLv3|OP_NO_SSLv2|OP_NO_COMPRESSION: 2197947391>
```

SSLContext.protocol

The protocol version chosen when constructing the context. This attribute is read-only.

SSLContext.hostname_checks_common_name

Whether *check_hostname* falls back to verify the cert's subject common name in the absence of a subject alternative name extension (default: true).

New in version 3.7.

Note: Only writeable with OpenSSL 1.1.0 or higher.

SSLContext.verify_flags

The flags for certificate verification operations. You can set flags like *VERIFY_CRL_CHECK_LEAF* by ORing them together. By default OpenSSL does neither require nor verify certificate revocation lists (CRLs). Available only with openssl version 0.9.8+.

New in version 3.4.

Changed in version 3.6: *SSLContext.verify_flags* returns *VerifyFlags* flags:

```
>>> ssl.create_default_context().verify_flags
<VerifyFlags.VERIFY_X509_TRUSTED_FIRST: 32768>
```

SSLContext.verify_mode

Whether to try to verify other peers' certificates and how to behave if verification fails. This attribute must be one of *CERT_NONE*, *CERT_OPTIONAL* or *CERT_REQUIRED*.

Changed in version 3.6: *SSLContext.verify_mode* returns *VerifyMode* enum:

```
>>> ssl.create_default_context().verify_mode
<VerifyMode.CERT_REQUIRED: 2>
```

19.2.4 Certificates

Certificates in general are part of a public-key / private-key system. In this system, each *principal*, (which may be a machine, or a person, or an organization) is assigned a unique two-part encryption key. One part of the key is public, and is called the *public key*; the other part is kept secret, and is called the *private key*. The two parts are related, in that if you encrypt a message with one of the parts, you can decrypt it with the other part, and **only** with the other part.

A certificate contains information about two principals. It contains the name of a *subject*, and the subject's public key. It also contains a statement by a second principal, the *issuer*, that the subject is who they claim to be, and that this is indeed the subject's public key. The issuer's statement is signed with the issuer's private key, which only the issuer knows. However, anyone can verify the issuer's statement by finding the issuer's public key, decrypting the statement with it, and comparing it to the other information in the certificate. The certificate also contains information about the time period over which it is valid. This is expressed as two fields, called "notBefore" and "notAfter".

In the Python use of certificates, a client or server can use a certificate to prove who they are. The other side of a network connection can also be required to produce a certificate, and that certificate can be validated to the satisfaction of the client or server that requires such validation. The connection attempt can be set to raise an exception if the validation fails. Validation is done automatically, by the underlying OpenSSL framework; the application need not concern itself with its mechanics. But the application does usually need to provide sets of certificates to allow this process to take place.

Python uses files to contain certificates. They should be formatted as "PEM" (see **RFC 1422**), which is a base-64 encoded form wrapped with a header line and a footer line:

```
-----BEGIN CERTIFICATE-----
... (certificate in base64 PEM encoding) ...
-----END CERTIFICATE-----
```

Certificate chains

The Python files which contain certificates can contain a sequence of certificates, sometimes called a *certificate chain*. This chain should start with the specific certificate for the principal who "is" the client or server, and then the certificate for the issuer of that certificate, and then the certificate for the issuer of *that* certificate, and so on up the chain till you get to a certificate which is *self-signed*, that is, a certificate which has the same subject and issuer, sometimes called a *root certificate*. The certificates should just be concatenated together in the certificate file. For example, suppose we had a three certificate chain, from our server certificate to the certificate of the certification authority that signed our server certificate, to the root certificate of the agency which issued the certification authority's certificate:

```
-----BEGIN CERTIFICATE-----
... (certificate for your server)...
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
... (the certificate for the CA)...
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
... (the root certificate for the CA's issuer)...
-----END CERTIFICATE-----
```

CA certificates

If you are going to require validation of the other side of the connection's certificate, you need to provide a "CA certs" file, filled with the certificate chains for each issuer you are willing to trust. Again, this file just contains these chains concatenated together. For validation, Python will use the first chain it finds in the file which matches. The platform's certificates file can be used by calling *SSLContext.load_default_certs()*, this is done automatically with *create_default_context()*.

Combined key and certificate

Often the private key is stored in the same file as the certificate; in this case, only the `certfile` parameter to *SSLContext.load_cert_chain()* and *wrap_socket()* needs to be passed. If the private key is stored with the certificate, it should come before the first certificate in the certificate chain:

```
-----BEGIN RSA PRIVATE KEY-----
... (private key in base64 encoding) ...
-----END RSA PRIVATE KEY-----
-----BEGIN CERTIFICATE-----
... (certificate in base64 PEM encoding) ...
-----END CERTIFICATE-----
```

Self-signed certificates

If you are going to create a server that provides SSL-encrypted connection services, you will need to acquire a certificate for that service. There are many ways of acquiring appropriate certificates, such as buying one from a certification authority. Another common practice is to generate a self-signed certificate. The simplest way to do this is with the OpenSSL package, using something like the following:

```
% openssl req -new -x509 -days 365 -nodes -out cert.pem -keyout cert.pem
Generating a 1024 bit RSA private key
.......++++++
..............................++++++
writing new private key to 'cert.pem'
-----
You are about to be asked to enter information that will be incorporated
into your certificate request.
What you are about to enter is what is called a Distinguished Name or a DN.
There are quite a few fields but you can leave some blank
For some fields there will be a default value,
If you enter '.', the field will be left blank.
-----
Country Name (2 letter code) [AU]:US
State or Province Name (full name) [Some-State]:MyState
Locality Name (eg, city) []:Some City
Organization Name (eg, company) [Internet Widgits Pty Ltd]:My Organization, Inc.
Organizational Unit Name (eg, section) []:My Group
Common Name (eg, YOUR name) []:myserver.mygroup.myorganization.com
Email Address []:ops@myserver.mygroup.myorganization.com
%
```

The disadvantage of a self-signed certificate is that it is its own root certificate, and no one else will have it in their cache of known (and trusted) root certificates.

19.2.5 Examples

Testing for SSL support

To test for the presence of SSL support in a Python installation, user code should use the following idiom:

```
try:
    import ssl
except ImportError:
    pass
else:
    ...  # do something that requires SSL support
```

Client-side operation

This example creates a SSL context with the recommended security settings for client sockets, including automatic certificate verification:

```
>>> context = ssl.create_default_context()
```

If you prefer to tune security settings yourself, you might create a context from scratch (but beware that you might not get the settings right):

```
>>> context = ssl.SSLContext()
>>> context.verify_mode = ssl.CERT_REQUIRED
>>> context.check_hostname = True
>>> context.load_verify_locations("/etc/ssl/certs/ca-bundle.crt")
```

(this snippet assumes your operating system places a bundle of all CA certificates in `/etc/ssl/certs/ca-bundle.crt`; if not, you'll get an error and have to adjust the location)

When you use the context to connect to a server, *CERT_REQUIRED* validates the server certificate: it ensures that the server certificate was signed with one of the CA certificates, and checks the signature for correctness:

```
>>> conn = context.wrap_socket(socket.socket(socket.AF_INET),
...                            server_hostname="www.python.org")
>>> conn.connect(("www.python.org", 443))
```

You may then fetch the certificate:

```
>>> cert = conn.getpeercert()
```

Visual inspection shows that the certificate does identify the desired service (that is, the HTTPS host `www.python.org`):

```
>>> pprint.pprint(cert)
{'OCSP': ('http://ocsp.digicert.com',),
 'caIssuers': ('http://cacerts.digicert.com/DigiCertSHA2ExtendedValidationServerCA.crt',),
 'crlDistributionPoints': ('http://crl3.digicert.com/sha2-ev-server-g1.crl',
                           'http://crl4.digicert.com/sha2-ev-server-g1.crl'),
 'issuer': ((('countryName', 'US'),),
            (('organizationName', 'DigiCert Inc'),),
            (('organizationalUnitName', 'www.digicert.com'),),
            (('commonName', 'DigiCert SHA2 Extended Validation Server CA'),)),
 'notAfter': 'Sep  9 12:00:00 2016 GMT',
 'notBefore': 'Sep  5 00:00:00 2014 GMT',
```

(continues on next page)

(continued from previous page)

```
 'serialNumber': '01BB6F00122B177F36CAB49CEA8B6B26',
 'subject': ((('businessCategory', 'Private Organization'),),
             (('1.3.6.1.4.1.311.60.2.1.3', 'US'),),
             (('1.3.6.1.4.1.311.60.2.1.2', 'Delaware'),),
             (('serialNumber', '3359300'),),
             (('streetAddress', '16 Allen Rd'),),
             (('postalCode', '03894-4801'),),
             (('countryName', 'US'),),
             (('stateOrProvinceName', 'NH'),),
             (('localityName', 'Wolfeboro,'),),
             (('organizationName', 'Python Software Foundation'),),
             (('commonName', 'www.python.org'),)),
 'subjectAltName': (('DNS', 'www.python.org'),
                    ('DNS', 'python.org'),
                    ('DNS', 'pypi.org'),
                    ('DNS', 'docs.python.org'),
                    ('DNS', 'testpypi.org'),
                    ('DNS', 'bugs.python.org'),
                    ('DNS', 'wiki.python.org'),
                    ('DNS', 'hg.python.org'),
                    ('DNS', 'mail.python.org'),
                    ('DNS', 'packaging.python.org'),
                    ('DNS', 'pythonhosted.org'),
                    ('DNS', 'www.pythonhosted.org'),
                    ('DNS', 'test.pythonhosted.org'),
                    ('DNS', 'us.pycon.org'),
                    ('DNS', 'id.python.org')),
 'version': 3}
```

Now the SSL channel is established and the certificate verified, you can proceed to talk with the server:

```
>>> conn.sendall(b"HEAD / HTTP/1.0\r\nHost: linuxfr.org\r\n\r\n")
>>> pprint.pprint(conn.recv(1024).split(b"\r\n"))
[b'HTTP/1.1 200 OK',
 b'Date: Sat, 18 Oct 2014 18:27:20 GMT',
 b'Server: nginx',
 b'Content-Type: text/html; charset=utf-8',
 b'X-Frame-Options: SAMEORIGIN',
 b'Content-Length: 45679',
 b'Accept-Ranges: bytes',
 b'Via: 1.1 varnish',
 b'Age: 2188',
 b'X-Served-By: cache-lcy1134-LCY',
 b'X-Cache: HIT',
 b'X-Cache-Hits: 11',
 b'Vary: Cookie',
 b'Strict-Transport-Security: max-age=63072000; includeSubDomains',
 b'Connection: close',
 b'',
 b'']
```

See the discussion of *Security considerations* below.

Server-side operation

For server operation, typically you'll need to have a server certificate, and private key, each in a file. You'll first create a context holding the key and the certificate, so that clients can check your authenticity. Then you'll open a socket, bind it to a port, call `listen()` on it, and start waiting for clients to connect:

```
import socket, ssl

context = ssl.create_default_context(ssl.Purpose.CLIENT_AUTH)
context.load_cert_chain(certfile="mycertfile", keyfile="mykeyfile")

bindsocket = socket.socket()
bindsocket.bind(('myaddr.mydomain.com', 10023))
bindsocket.listen(5)
```

When a client connects, you'll call `accept()` on the socket to get the new socket from the other end, and use the context's *SSLContext.wrap_socket()* method to create a server-side SSL socket for the connection:

```
while True:
    newsocket, fromaddr = bindsocket.accept()
    connstream = context.wrap_socket(newsocket, server_side=True)
    try:
        deal_with_client(connstream)
    finally:
        connstream.shutdown(socket.SHUT_RDWR)
        connstream.close()
```

Then you'll read data from the `connstream` and do something with it till you are finished with the client (or the client is finished with you):

```
def deal_with_client(connstream):
    data = connstream.recv(1024)
    # empty data means the client is finished with us
    while data:
        if not do_something(connstream, data):
            # we'll assume do_something returns False
            # when we're finished with client
            break
        data = connstream.recv(1024)
    # finished with client
```

And go back to listening for new client connections (of course, a real server would probably handle each client connection in a separate thread, or put the sockets in *non-blocking mode* and use an event loop).

19.2.6 Notes on non-blocking sockets

SSL sockets behave slightly different than regular sockets in non-blocking mode. When working with non-blocking sockets, there are thus several things you need to be aware of:

- Most *SSLSocket* methods will raise either *SSLWantWriteError* or *SSLWantReadError* instead of *BlockingIOError* if an I/O operation would block. *SSLWantReadError* will be raised if a read operation on the underlying socket is necessary, and *SSLWantWriteError* for a write operation on the underlying socket. Note that attempts to *write* to an SSL socket may require *reading* from the underlying socket first, and attempts to *read* from the SSL socket may require a prior *write* to the underlying socket.

  Changed in version 3.5: In earlier Python versions, the `SSLSocket.send()` method returned zero instead of raising *SSLWantWriteError* or *SSLWantReadError*.

- Calling *select()* tells you that the OS-level socket can be read from (or written to), but it does not imply that there is sufficient data at the upper SSL layer. For example, only part of an SSL frame might have arrived. Therefore, you must be ready to handle `SSLSocket.recv()` and `SSLSocket.send()` failures, and retry after another call to *select()*.
- Conversely, since the SSL layer has its own framing, a SSL socket may still have data available for reading without *select()* being aware of it. Therefore, you should first call `SSLSocket.recv()` to drain any potentially available data, and then only block on a *select()* call if still necessary.

  (of course, similar provisions apply when using other primitives such as *poll()*, or those in the *selectors* module)
- The SSL handshake itself will be non-blocking: the *SSLSocket.do_handshake()* method has to be retried until it returns successfully. Here is a synopsis using *select()* to wait for the socket's readiness:

```
while True:
    try:
        sock.do_handshake()
        break
    except ssl.SSLWantReadError:
        select.select([sock], [], [])
    except ssl.SSLWantWriteError:
        select.select([], [sock], [])
```

See also:

The *asyncio* module supports *non-blocking SSL sockets* and provides a higher level API. It polls for events using the *selectors* module and handles *SSLWantWriteError*, *SSLWantReadError* and *BlockingIOError* exceptions. It runs the SSL handshake asynchronously as well.

19.2.7 Memory BIO Support

New in version 3.5.

Ever since the SSL module was introduced in Python 2.6, the *SSLSocket* class has provided two related but distinct areas of functionality:

- SSL protocol handling
- Network IO

The network IO API is identical to that provided by *socket.socket*, from which *SSLSocket* also inherits. This allows an SSL socket to be used as a drop-in replacement for a regular socket, making it very easy to add SSL support to an existing application.

Combining SSL protocol handling and network IO usually works well, but there are some cases where it doesn't. An example is async IO frameworks that want to use a different IO multiplexing model than the "select/poll on a file descriptor" (readiness based) model that is assumed by *socket.socket* and by the internal OpenSSL socket IO routines. This is mostly relevant for platforms like Windows where this model is not efficient. For this purpose, a reduced scope variant of *SSLSocket* called *SSLObject* is provided.

class ssl.SSLObject

A reduced-scope variant of *SSLSocket* representing an SSL protocol instance that does not contain any network IO methods. This class is typically used by framework authors that want to implement asynchronous IO for SSL through memory buffers.

This class implements an interface on top of a low-level SSL object as implemented by OpenSSL. This object captures the state of an SSL connection but does not provide any network IO itself. IO needs to be performed through separate "BIO" objects which are OpenSSL's IO abstraction layer.

This class has no public constructor. An *SSLObject* instance must be created using the *wrap_bio()* method. This method will create the *SSLObject* instance and bind it to a pair of BIOs. The *incoming* BIO is used to pass data from Python to the SSL protocol instance, while the *outgoing* BIO is used to pass data the other way around.

The following methods are available:

- *context*
- *server_side*
- *server_hostname*
- *session*
- *session_reused*
- *read()*
- *write()*
- *getpeercert()*
- *selected_npn_protocol()*
- *cipher()*
- *shared_ciphers()*
- *compression()*
- *pending()*
- *do_handshake()*
- *unwrap()*
- *get_channel_binding()*

When compared to *SSLSocket*, this object lacks the following features:

- Any form of network IO; `recv()` and `send()` read and write only to the underlying *MemoryBIO* buffers.
- There is no *do_handshake_on_connect* machinery. You must always manually call *do_handshake()* to start the handshake.
- There is no handling of *suppress_ragged_eofs*. All end-of-file conditions that are in violation of the protocol are reported via the *SSLEOFError* exception.
- The method *unwrap()* call does not return anything, unlike for an SSL socket where it returns the underlying socket.
- The *server_name_callback* callback passed to *SSLContext.set_servername_callback()* will get an *SSLObject* instance instead of a *SSLSocket* instance as its first parameter.

Some notes related to the use of *SSLObject*:

- All IO on an *SSLObject* is *non-blocking*. This means that for example *read()* will raise an *SSLWantReadError* if it needs more data than the incoming BIO has available.
- There is no module-level `wrap_bio()` call like there is for *wrap_socket()*. An *SSLObject* is always created via an *SSLContext*.

Changed in version 3.7: *SSLObject* instances must to created with *wrap_bio()*. In earlier versions, it was possible to create instances directly. This was never documented or officially supported.

An SSLObject communicates with the outside world using memory buffers. The class *MemoryBIO* provides a memory buffer that can be used for this purpose. It wraps an OpenSSL memory BIO (Basic IO) object:

class ssl.MemoryBIO
A memory buffer that can be used to pass data between Python and an SSL protocol instance.

pending
Return the number of bytes currently in the memory buffer.

eof
A boolean indicating whether the memory BIO is current at the end-of-file position.

read(*n=-1*)
Read up to *n* bytes from the memory buffer. If *n* is not specified or negative, all bytes are returned.

write(*buf*)
Write the bytes from *buf* to the memory BIO. The *buf* argument must be an object supporting the buffer protocol.

The return value is the number of bytes written, which is always equal to the length of *buf*.

write_eof()
Write an EOF marker to the memory BIO. After this method has been called, it is illegal to call *write()*. The attribute *eof* will become true after all data currently in the buffer has been read.

19.2.8 SSL session

New in version 3.6.

class ssl.SSLSession
Session object used by *session*.

id

time

timeout

ticket_lifetime_hint

has_ticket

19.2.9 Security considerations

Best defaults

For **client use**, if you don't have any special requirements for your security policy, it is highly recommended that you use the *create_default_context()* function to create your SSL context. It will load the system's trusted CA certificates, enable certificate validation and hostname checking, and try to choose reasonably secure protocol and cipher settings.

For example, here is how you would use the *smtplib.SMTP* class to create a trusted, secure connection to a SMTP server:

```
>>> import ssl, smtplib
>>> smtp = smtplib.SMTP("mail.python.org", port=587)
>>> context = ssl.create_default_context()
>>> smtp.starttls(context=context)
(220, b'2.0.0 Ready to start TLS')
```

If a client certificate is needed for the connection, it can be added with *SSLContext.load_cert_chain()*.

By contrast, if you create the SSL context by calling the *SSLContext* constructor yourself, it will not have certificate validation nor hostname checking enabled by default. If you do so, please read the paragraphs below to achieve a good security level.

Manual settings

Verifying certificates

When calling the *SSLContext* constructor directly, *CERT_NONE* is the default. Since it does not authenticate the other peer, it can be insecure, especially in client mode where most of time you would like to ensure the authenticity of the server you're talking to. Therefore, when in client mode, it is highly recommended to use *CERT_REQUIRED*. However, it is in itself not sufficient; you also have to check that the server certificate, which can be obtained by calling *SSLSocket.getpeercert()*, matches the desired service. For many protocols and applications, the service can be identified by the hostname; in this case, the *match_hostname()* function can be used. This common check is automatically performed when *SSLContext.check_hostname* is enabled.

Changed in version 3.7: Hostname matchings is now performed by OpenSSL. Python no longer uses *match_hostname()*.

In server mode, if you want to authenticate your clients using the SSL layer (rather than using a higher-level authentication mechanism), you'll also have to specify *CERT_REQUIRED* and similarly check the client certificate.

Protocol versions

SSL versions 2 and 3 are considered insecure and are therefore dangerous to use. If you want maximum compatibility between clients and servers, it is recommended to use *PROTOCOL_TLS_CLIENT* or *PROTOCOL_TLS_SERVER* as the protocol version. SSLv2 and SSLv3 are disabled by default.

```
>>> client_context = ssl.SSLContext(ssl.PROTOCOL_TLS_CLIENT)
>>> client_context.options |= ssl.OP_NO_TLSv1
>>> client_context.options |= ssl.OP_NO_TLSv1_1
```

The SSL context created above will only allow TLSv1.2 and later (if supported by your system) connections to a server. *PROTOCOL_TLS_CLIENT* implies certificate validation and hostname checks by default. You have to load certificates into the context.

Cipher selection

If you have advanced security requirements, fine-tuning of the ciphers enabled when negotiating a SSL session is possible through the *SSLContext.set_ciphers()* method. Starting from Python 3.2.3, the ssl module disables certain weak ciphers by default, but you may want to further restrict the cipher choice. Be sure to read OpenSSL's documentation about the cipher list format. If you want to check which ciphers are enabled by a given cipher list, use *SSLContext.get_ciphers()* or the `openssl ciphers` command on your system.

Multi-processing

If using this module as part of a multi-processed application (using, for example the *multiprocessing* or *concurrent.futures* modules), be aware that OpenSSL's internal random number generator does not properly handle forked processes. Applications must change the PRNG state of the parent process if they use any SSL feature with *os.fork()*. Any successful call of *RAND_add()*, *RAND_bytes()* or *RAND_pseudo_bytes()* is sufficient.

19.2.10 TLS 1.3

New in version 3.7.

Python has provisional and experimental support for TLS 1.3 with OpenSSL 1.1.1. The new protocol behaves slightly differently than previous version of TLS/SSL. Some new TLS 1.3 features are not yet available.

- TLS 1.3 uses a disjunct set of cipher suites. All AES-GCM and ChaCha20 cipher suites are enabled by default. The method *SSLContext.set_ciphers()* cannot enable or disable any TLS 1.3 ciphers yet, but `SSLContext.get_cipers()` returns them.
- Session tickets are no longer sent as part of the initial handshake and are handled differently. *SSLSocket.session* and *SSLSession* are not compatible with TLS 1.3.
- Client-side certificates are also no longer verified during the initial handshake. A server can request a certificate at any time. Clients process certificate requests while they send or receive application data from the server.
- TLS 1.3 features like early data, deferred TLS client cert request, signature algorithm configuration, and rekeying are not supported yet.

19.2.11 LibreSSL support

LibreSSL is a fork of OpenSSL 1.0.1. The ssl module has limited support for LibreSSL. Some features are not available when the ssl module is compiled with LibreSSL.

- LibreSSL >= 2.6.1 no longer supports NPN. The methods *SSLContext.set_npn_protocols()* and *SSLSocket.selected_npn_protocol()* are not available.
- *SSLContext.set_default_verify_paths()* ignores the env vars `SSL_CERT_FILE` and `SSL_CERT_PATH` although *get_default_verify_paths()* still reports them.

19.3 `select` — Waiting for I/O completion

This module provides access to the `select()` and `poll()` functions available in most operating systems, `devpoll()` available on Solaris and derivatives, `epoll()` available on Linux 2.5+ and `kqueue()` available on

most BSD. Note that on Windows, it only works for sockets; on other operating systems, it also works for other file types (in particular, on Unix, it works on pipes). It cannot be used on regular files to determine whether a file has grown since it was last read.

Note: The *selectors* module allows high-level and efficient I/O multiplexing, built upon the *select* module primitives. Users are encouraged to use the *selectors* module instead, unless they want precise control over the OS-level primitives used.

The module defines the following:

exception select.error
A deprecated alias of *OSError*.

Changed in version 3.3: Following **PEP 3151**, this class was made an alias of *OSError*.

select.devpoll()
(Only supported on Solaris and derivatives.) Returns a `/dev/poll` polling object; see section */dev/poll Polling Objects* below for the methods supported by devpoll objects.

`devpoll()` objects are linked to the number of file descriptors allowed at the time of instantiation. If your program reduces this value, `devpoll()` will fail. If your program increases this value, `devpoll()` may return an incomplete list of active file descriptors.

The new file descriptor is *non-inheritable*.

New in version 3.3.

Changed in version 3.4: The new file descriptor is now non-inheritable.

select.epoll(*sizehint=-1*, *flags=0*)
(Only supported on Linux 2.5.44 and newer.) Return an edge polling object, which can be used as Edge or Level Triggered interface for I/O events.

sizehint informs epoll about the expected number of events to be registered. It must be positive, or *-1* to use the default. It is only used on older systems where `epoll_create1()` is not available; otherwise it has no effect (though its value is still checked).

flags is deprecated and completely ignored. However, when supplied, its value must be `0` or `select.EPOLL_CLOEXEC`, otherwise `OSError` is raised.

See the *Edge and Level Trigger Polling (epoll) Objects* section below for the methods supported by epolling objects.

`epoll` objects support the context management protocol: when used in a `with` statement, the new file descriptor is automatically closed at the end of the block.

The new file descriptor is *non-inheritable*.

Changed in version 3.3: Added the *flags* parameter.

Changed in version 3.4: Support for the `with` statement was added. The new file descriptor is now non-inheritable.

Deprecated since version 3.4: The *flags* parameter. `select.EPOLL_CLOEXEC` is used by default now. Use *os.set_inheritable()* to make the file descriptor inheritable.

select.poll()
(Not supported by all operating systems.) Returns a polling object, which supports registering and unregistering file descriptors, and then polling them for I/O events; see section *Polling Objects* below for the methods supported by polling objects.

select.kqueue()
(Only supported on BSD.) Returns a kernel queue object; see section *Kqueue Objects* below for the methods supported by kqueue objects.

The new file descriptor is *non-inheritable*.

Changed in version 3.4: The new file descriptor is now non-inheritable.

`select.kevent`(*ident*, *filter=KQ_FILTER_READ*, *flags=KQ_EV_ADD*, *fflags=0*, *data=0*, *udata=0*)
(Only supported on BSD.) Returns a kernel event object; see section *Kevent Objects* below for the methods supported by kevent objects.

`select.select`(*rlist*, *wlist*, *xlist*[, *timeout*])
This is a straightforward interface to the Unix `select()` system call. The first three arguments are sequences of 'waitable objects': either integers representing file descriptors or objects with a parameterless method named *`fileno()`* returning such an integer:

- *rlist*: wait until ready for reading
- *wlist*: wait until ready for writing
- *xlist*: wait for an "exceptional condition" (see the manual page for what your system considers such a condition)

Empty sequences are allowed, but acceptance of three empty sequences is platform-dependent. (It is known to work on Unix but not on Windows.) The optional *timeout* argument specifies a time-out as a floating point number in seconds. When the *timeout* argument is omitted the function blocks until at least one file descriptor is ready. A time-out value of zero specifies a poll and never blocks.

The return value is a triple of lists of objects that are ready: subsets of the first three arguments. When the time-out is reached without a file descriptor becoming ready, three empty lists are returned.

Among the acceptable object types in the sequences are Python *file objects* (e.g. `sys.stdin`, or objects returned by *`open()`* or *`os.popen()`*), socket objects returned by *`socket.socket()`*. You may also define a *wrapper* class yourself, as long as it has an appropriate *`fileno()`* method (that really returns a file descriptor, not just a random integer).

Note: File objects on Windows are not acceptable, but sockets are. On Windows, the underlying `select()` function is provided by the WinSock library, and does not handle file descriptors that don't originate from WinSock.

Changed in version 3.5: The function is now retried with a recomputed timeout when interrupted by a signal, except if the signal handler raises an exception (see **PEP 475** for the rationale), instead of raising *`InterruptedError`*.

`select.PIPE_BUF`
The minimum number of bytes which can be written without blocking to a pipe when the pipe has been reported as ready for writing by *`select()`*, *`poll()`* or another interface in this module. This doesn't apply to other kind of file-like objects such as sockets.

This value is guaranteed by POSIX to be at least 512. Availability: Unix.

New in version 3.2.

19.3.1 `/dev/poll` Polling Objects

Solaris and derivatives have `/dev/poll`. While `select()` is O(highest file descriptor) and `poll()` is O(number of file descriptors), `/dev/poll` is O(active file descriptors).

`/dev/poll` behaviour is very close to the standard `poll()` object.

`devpoll.close()`
Close the file descriptor of the polling object.

New in version 3.4.

`devpoll.closed`
`True` if the polling object is closed.

New in version 3.4.

`devpoll.fileno()`
Return the file descriptor number of the polling object.

New in version 3.4.

`devpoll.register(`*fd*[, *eventmask*]`)`
Register a file descriptor with the polling object. Future calls to the *poll()* method will then check whether the file descriptor has any pending I/O events. *fd* can be either an integer, or an object with a *fileno()* method that returns an integer. File objects implement `fileno()`, so they can also be used as the argument.

eventmask is an optional bitmask describing the type of events you want to check for. The constants are the same that with `poll()` object. The default value is a combination of the constants `POLLIN`, `POLLPRI`, and `POLLOUT`.

> **Warning:** Registering a file descriptor that's already registered is not an error, but the result is undefined. The appropriate action is to unregister or modify it first. This is an important difference compared with `poll()`.

`devpoll.modify(`*fd*[, *eventmask*]`)`
This method does an *unregister()* followed by a *register()*. It is (a bit) more efficient that doing the same explicitly.

`devpoll.unregister(`*fd*`)`
Remove a file descriptor being tracked by a polling object. Just like the *register()* method, *fd* can be an integer or an object with a *fileno()* method that returns an integer.

Attempting to remove a file descriptor that was never registered is safely ignored.

`devpoll.poll(`[*timeout*]`)`
Polls the set of registered file descriptors, and returns a possibly-empty list containing `(fd, event)` 2-tuples for the descriptors that have events or errors to report. *fd* is the file descriptor, and *event* is a bitmask with bits set for the reported events for that descriptor — `POLLIN` for waiting input, `POLLOUT` to indicate that the descriptor can be written to, and so forth. An empty list indicates that the call timed out and no file descriptors had any events to report. If *timeout* is given, it specifies the length of time in milliseconds which the system will wait for events before returning. If *timeout* is omitted, -1, or *None*, the call will block until there is an event for this poll object.

Changed in version 3.5: The function is now retried with a recomputed timeout when interrupted by a signal, except if the signal handler raises an exception (see **PEP 475** for the rationale), instead of raising *InterruptedError*.

19.3.2 Edge and Level Trigger Polling (epoll) Objects

https://linux.die.net/man/4/epoll

eventmask

Constant	Meaning
EPOLLIN	Available for read
EPOLLOUT	Available for write
EPOLLPRI	Urgent data for read
EPOLLERR	Error condition happened on the assoc. fd
EPOLLHUP	Hang up happened on the assoc. fd
EPOLLET	Set Edge Trigger behavior, the default is Level Trigger behavior
EPOLLONESHOT	Set one-shot behavior. After one event is pulled out, the fd is internally disabled
EPOLLEXCLUSIVE	Wake only one epoll object when the associated fd has an event. The default (if this flag is not set) is to wake all epoll objects polling on a fd.
EPOLLRDHUP	Stream socket peer closed connection or shut down writing half of connection.
EPOLLRDNORM	Equivalent to EPOLLIN
EPOLLRDBAND	Priority data band can be read.
EPOLLWRNORM	Equivalent to EPOLLOUT
EPOLLWRBAND	Priority data may be written.
EPOLLMSG	Ignored.

epoll.close()
Close the control file descriptor of the epoll object.

epoll.closed
`True` if the epoll object is closed.

epoll.fileno()
Return the file descriptor number of the control fd.

epoll.fromfd(*fd*)
Create an epoll object from a given file descriptor.

epoll.register(*fd*[, *eventmask*])
Register a fd descriptor with the epoll object.

epoll.modify(*fd*, *eventmask*)
Modify a registered file descriptor.

epoll.unregister(*fd*)
Remove a registered file descriptor from the epoll object.

epoll.poll(*timeout=-1*, *maxevents=-1*)
Wait for events. timeout in seconds (float)

Changed in version 3.5: The function is now retried with a recomputed timeout when interrupted by a signal, except if the signal handler raises an exception (see **PEP 475** for the rationale), instead of raising *InterruptedError*.

19.3.3 Polling Objects

The `poll()` system call, supported on most Unix systems, provides better scalability for network servers that service many, many clients at the same time. `poll()` scales better because the system call only requires listing the file descriptors of interest, while `select()` builds a bitmap, turns on bits for the fds of interest, and then afterward the whole bitmap has to be linearly scanned again. `select()` is O(highest file descriptor), while `poll()` is O(number of file descriptors).

poll.register(*fd*[, *eventmask*])
Register a file descriptor with the polling object. Future calls to the *poll()* method will then check whether the file descriptor has any pending I/O events. *fd* can be either an integer, or an object with a

fileno() method that returns an integer. File objects implement `fileno()`, so they can also be used as the argument.

eventmask is an optional bitmask describing the type of events you want to check for, and can be a combination of the constants `POLLIN`, `POLLPRI`, and `POLLOUT`, described in the table below. If not specified, the default value used will check for all 3 types of events.

Constant	Meaning
`POLLIN`	There is data to read
`POLLPRI`	There is urgent data to read
`POLLOUT`	Ready for output: writing will not block
`POLLERR`	Error condition of some sort
`POLLHUP`	Hung up
`POLLRDHUP`	Stream socket peer closed connection, or shut down writing half of connection
`POLLNVAL`	Invalid request: descriptor not open

Registering a file descriptor that's already registered is not an error, and has the same effect as registering the descriptor exactly once.

`poll.modify(`*fd*, *eventmask*`)`
Modifies an already registered fd. This has the same effect as `register(fd, eventmask)`. Attempting to modify a file descriptor that was never registered causes an *OSError* exception with errno `ENOENT` to be raised.

`poll.unregister(`*fd*`)`
Remove a file descriptor being tracked by a polling object. Just like the *register()* method, *fd* can be an integer or an object with a *fileno()* method that returns an integer.

Attempting to remove a file descriptor that was never registered causes a *KeyError* exception to be raised.

`poll.poll(`[*timeout*]`)`
Polls the set of registered file descriptors, and returns a possibly-empty list containing `(fd, event)` 2-tuples for the descriptors that have events or errors to report. *fd* is the file descriptor, and *event* is a bitmask with bits set for the reported events for that descriptor — `POLLIN` for waiting input, `POLLOUT` to indicate that the descriptor can be written to, and so forth. An empty list indicates that the call timed out and no file descriptors had any events to report. If *timeout* is given, it specifies the length of time in milliseconds which the system will wait for events before returning. If *timeout* is omitted, negative, or *None*, the call will block until there is an event for this poll object.

Changed in version 3.5: The function is now retried with a recomputed timeout when interrupted by a signal, except if the signal handler raises an exception (see **PEP 475** for the rationale), instead of raising *InterruptedError*.

19.3.4 Kqueue Objects

`kqueue.close()`
Close the control file descriptor of the kqueue object.

`kqueue.closed`
`True` if the kqueue object is closed.

`kqueue.fileno()`
Return the file descriptor number of the control fd.

`kqueue.fromfd(`*fd*`)`
Create a kqueue object from a given file descriptor.

`kqueue.control(`*changelist*, *max_events*[, *timeout=None*]`)` → eventlist
Low level interface to kevent

- changelist must be an iterable of kevent object or `None`
- max_events must be 0 or a positive integer
- timeout in seconds (floats possible)

Changed in version 3.5: The function is now retried with a recomputed timeout when interrupted by a signal, except if the signal handler raises an exception (see **PEP 475** for the rationale), instead of raising *InterruptedError*.

19.3.5 Kevent Objects

https://www.freebsd.org/cgi/man.cgi?query=kqueue&sektion=2

`kevent.ident`
Value used to identify the event. The interpretation depends on the filter but it's usually the file descriptor. In the constructor ident can either be an int or an object with a *fileno()* method. kevent stores the integer internally.

`kevent.filter`
Name of the kernel filter.

Constant	Meaning
KQ_FILTER_READ	Takes a descriptor and returns whenever there is data available to read
KQ_FILTER_WRITE	Takes a descriptor and returns whenever there is data available to write
KQ_FILTER_AIO	AIO requests
KQ_FILTER_VNODE	Returns when one or more of the requested events watched in *fflag* occurs
KQ_FILTER_PROC	Watch for events on a process id
KQ_FILTER_NETDEV	Watch for events on a network device [not available on Mac OS X]
KQ_FILTER_SIGNAL	Returns whenever the watched signal is delivered to the process
KQ_FILTER_TIMER	Establishes an arbitrary timer

`kevent.flags`
Filter action.

Constant	Meaning
KQ_EV_ADD	Adds or modifies an event
KQ_EV_DELETE	Removes an event from the queue
KQ_EV_ENABLE	Permitscontrol() to returns the event
KQ_EV_DISABLE	Disablesevent
KQ_EV_ONESHOT	Removes event after first occurrence
KQ_EV_CLEAR	Reset the state after an event is retrieved
KQ_EV_SYSFLAGS	internal event
KQ_EV_FLAG1	internal event
KQ_EV_EOF	Filter specific EOF condition
KQ_EV_ERROR	See return values

`kevent.fflags`
Filter specific flags.

KQ_FILTER_READ and KQ_FILTER_WRITE filter flags:

Constant	Meaning
KQ_NOTE_LOWAT	low water mark of a socket buffer

KQ_FILTER_VNODE filter flags:

Constant	Meaning
KQ_NOTE_DELETE	*unlink()* was called
KQ_NOTE_WRITE	a write occurred
KQ_NOTE_EXTEND	the file was extended
KQ_NOTE_ATTRIB	an attribute was changed
KQ_NOTE_LINK	the link count has changed
KQ_NOTE_RENAME	the file was renamed
KQ_NOTE_REVOKE	access to the file was revoked

KQ_FILTER_PROC filter flags:

Constant	Meaning
KQ_NOTE_EXIT	the process has exited
KQ_NOTE_FORK	the process has called *fork()*
KQ_NOTE_EXEC	the process has executed a new process
KQ_NOTE_PCTRLMASK	internal filter flag
KQ_NOTE_PDATAMASK	internal filter flag
KQ_NOTE_TRACK	follow a process across *fork()*
KQ_NOTE_CHILD	returned on the child process for *NOTE_TRACK*
KQ_NOTE_TRACKERR	unable to attach to a child

KQ_FILTER_NETDEV filter flags (not available on Mac OS X):

Constant	Meaning
KQ_NOTE_LINKUP	link is up
KQ_NOTE_LINKDOWN	link is down
KQ_NOTE_LINKINV	link state is invalid

kevent.data
Filter specific data.

kevent.udata
User defined value.

19.4 selectors — High-level I/O multiplexing

New in version 3.4.

Source code: Lib/selectors.py

19.4.1 Introduction

This module allows high-level and efficient I/O multiplexing, built upon the *select* module primitives. Users are encouraged to use this module instead, unless they want precise control over the OS-level primitives used.

It defines a *BaseSelector* abstract base class, along with several concrete implementations (*KqueueSelector*, *EpollSelector*...), that can be used to wait for I/O readiness notification on multiple file objects. In the following, "file object" refers to any object with a `fileno()` method, or a raw file descriptor. See *file object*.

DefaultSelector is an alias to the most efficient implementation available on the current platform: this should be the default choice for most users.

Note: The type of file objects supported depends on the platform: on Windows, sockets are supported, but not pipes, whereas on Unix, both are supported (some other types may be supported as well, such as fifos or special file devices).

See also:

select Low-level I/O multiplexing module.

19.4.2 Classes

Classes hierarchy:

```
BaseSelector
+-- SelectSelector
+-- PollSelector
+-- EpollSelector
+-- DevpollSelector
+-- KqueueSelector
```

In the following, *events* is a bitwise mask indicating which I/O events should be waited for on a given file object. It can be a combination of the modules constants below:

Constant	Meaning
`EVENT_READ`	Available for read
`EVENT_WRITE`	Available for write

class selectors.SelectorKey

A *SelectorKey* is a *namedtuple* used to associate a file object to its underlying file descriptor, selected event mask and attached data. It is returned by several *BaseSelector* methods.

fileobj

File object registered.

fd

Underlying file descriptor.

events

Events that must be waited for on this file object.

data

Optional opaque data associated to this file object: for example, this could be used to store a per-client session ID.

class selectors.BaseSelector

A *BaseSelector* is used to wait for I/O event readiness on multiple file objects. It supports file stream registration, unregistration, and a method to wait for I/O events on those streams, with an optional timeout. It's an abstract base class, so cannot be instantiated. Use *DefaultSelector* instead, or one of *SelectSelector*, *KqueueSelector* etc. if you want to specifically use an implementation, and your platform supports it. *BaseSelector* and its concrete implementations support the *context manager* protocol.

abstractmethod register(*fileobj*, *events*, *data=None*)

Register a file object for selection, monitoring it for I/O events.

fileobj is the file object to monitor. It may either be an integer file descriptor or an object with a `fileno()` method. *events* is a bitwise mask of events to monitor. *data* is an opaque object.

This returns a new *SelectorKey* instance, or raises a *ValueError* in case of invalid event mask or file descriptor, or *KeyError* if the file object is already registered.

abstractmethod unregister(*fileobj*)

Unregister a file object from selection, removing it from monitoring. A file object shall be unregistered prior to being closed.

fileobj must be a file object previously registered.

This returns the associated *SelectorKey* instance, or raises a *KeyError* if *fileobj* is not registered. It will raise *ValueError* if *fileobj* is invalid (e.g. it has no `fileno()` method or its `fileno()` method has an invalid return value).

modify(*fileobj*, *events*, *data=None*)

Change a registered file object's monitored events or attached data.

This is equivalent to `BaseSelector.unregister(fileobj)()` followed by `BaseSelector.register(fileobj, events, data)()`, except that it can be implemented more efficiently.

This returns a new *SelectorKey* instance, or raises a *ValueError* in case of invalid event mask or file descriptor, or *KeyError* if the file object is not registered.

abstractmethod select(*timeout=None*)

Wait until some registered file objects become ready, or the timeout expires.

If `timeout > 0`, this specifies the maximum wait time, in seconds. If `timeout <= 0`, the call won't block, and will report the currently ready file objects. If *timeout* is `None`, the call will block until a monitored file object becomes ready.

This returns a list of `(key, events)` tuples, one for each ready file object.

key is the *SelectorKey* instance corresponding to a ready file object. *events* is a bitmask of events ready on this file object.

Note: This method can return before any file object becomes ready or the timeout has elapsed if the current process receives a signal: in this case, an empty list will be returned.

Changed in version 3.5: The selector is now retried with a recomputed timeout when interrupted by a signal if the signal handler did not raise an exception (see **PEP 475** for the rationale), instead of returning an empty list of events before the timeout.

close()

Close the selector.

This must be called to make sure that any underlying resource is freed. The selector shall not be used once it has been closed.

get_key(*fileobj*)
Return the key associated with a registered file object.

This returns the *SelectorKey* instance associated to this file object, or raises *KeyError* if the file object is not registered.

abstractmethod get_map()
Return a mapping of file objects to selector keys.

This returns a *Mapping* instance mapping registered file objects to their associated *SelectorKey* instance.

class selectors.DefaultSelector
The default selector class, using the most efficient implementation available on the current platform. This should be the default choice for most users.

class selectors.SelectSelector
select.select()-based selector.

class selectors.PollSelector
select.poll()-based selector.

class selectors.EpollSelector
select.epoll()-based selector.

fileno()
This returns the file descriptor used by the underlying *select.epoll()* object.

class selectors.DevpollSelector
select.devpoll()-based selector.

fileno()
This returns the file descriptor used by the underlying *select.devpoll()* object.

New in version 3.5.

class selectors.KqueueSelector
select.kqueue()-based selector.

fileno()
This returns the file descriptor used by the underlying *select.kqueue()* object.

19.4.3 Examples

Here is a simple echo server implementation:

```
import selectors
import socket

sel = selectors.DefaultSelector()

def accept(sock, mask):
    conn, addr = sock.accept()  # Should be ready
    print('accepted', conn, 'from', addr)
    conn.setblocking(False)
    sel.register(conn, selectors.EVENT_READ, read)

def read(conn, mask):
    data = conn.recv(1000)  # Should be ready
    if data:
        print('echoing', repr(data), 'to', conn)
```

(continues on next page)

(continued from previous page)

```
        conn.send(data)  # Hope it won't block
    else:
        print('closing', conn)
        sel.unregister(conn)
        conn.close()

sock = socket.socket()
sock.bind(('localhost', 1234))
sock.listen(100)
sock.setblocking(False)
sel.register(sock, selectors.EVENT_READ, accept)

while True:
    events = sel.select()
    for key, mask in events:
        callback = key.data
        callback(key.fileobj, mask)
```

19.5 `asyncio` — Asynchronous I/O, event loop, coroutines and tasks

New in version 3.4.

Source code: Lib/asyncio/

This module provides infrastructure for writing single-threaded concurrent code using coroutines, multiplexing I/O access over sockets and other resources, running network clients and servers, and other related primitives. Here is a more detailed list of the package contents:

- a pluggable *event loop* with various system-specific implementations;
- *transport* and *protocol* abstractions (similar to those in Twisted);
- concrete support for TCP, UDP, SSL, subprocess pipes, delayed calls, and others (some may be system-dependent);
- a *Future* class that mimics the one in the *concurrent.futures* module, but adapted for use with the event loop;
- coroutines and tasks based on `yield from` (**PEP 380**), to help write concurrent code in a sequential fashion;
- cancellation support for *Future*s and coroutines;
- *synchronization primitives* for use between coroutines in a single thread, mimicking those in the *threading* module;
- an interface for passing work off to a threadpool, for times when you absolutely, positively have to use a library that makes blocking I/O calls.

Asynchronous programming is more complex than classical "sequential" programming: see the *Develop with asyncio* page which lists common traps and explains how to avoid them. *Enable the debug mode* during development to detect common issues.

Table of contents:

19.5.1 Base Event Loop

Source code: Lib/asyncio/events.py

The event loop is the central execution device provided by *asyncio*. It provides multiple facilities, including:

- Registering, executing and cancelling delayed calls (timeouts).
- Creating client and server *transports* for various kinds of communication.
- Launching subprocesses and the associated *transports* for communication with an external program.
- Delegating costly function calls to a pool of threads.

class asyncio.BaseEventLoop
This class is an implementation detail. It is a subclass of *AbstractEventLoop* and may be a base class of concrete event loop implementations found in *asyncio*. It should not be used directly; use *AbstractEventLoop* instead. `BaseEventLoop` should not be subclassed by third-party code; the internal interface is not stable.

class asyncio.AbstractEventLoop
Abstract base class of event loops.

This class is *not thread safe*.

Run an event loop

AbstractEventLoop.run_forever()
Run until *stop()* is called. If *stop()* is called before *run_forever()* is called, this polls the I/O selector once with a timeout of zero, runs all callbacks scheduled in response to I/O events (and those that were already scheduled), and then exits. If *stop()* is called while *run_forever()* is running, this will run the current batch of callbacks and then exit. Note that callbacks scheduled by callbacks will not run in that case; they will run the next time *run_forever()* is called.

Changed in version 3.5.1.

AbstractEventLoop.run_until_complete(*future***)**
Run until the *Future* is done.

If the argument is a *coroutine object*, it is wrapped by *ensure_future()*.

Return the Future's result, or raise its exception.

AbstractEventLoop.is_running()
Returns running status of event loop.

AbstractEventLoop.stop()
Stop running the event loop.

This causes *run_forever()* to exit at the next suitable opportunity (see there for more details).

Changed in version 3.5.1.

AbstractEventLoop.is_closed()
Returns `True` if the event loop was closed.

New in version 3.4.2.

AbstractEventLoop.close()
Close the event loop. The loop must not be running. Pending callbacks will be lost.

This clears the queues and shuts down the executor, but does not wait for the executor to finish.

This is idempotent and irreversible. No other methods should be called after this one.

coroutine AbstractEventLoop.**shutdown_asyncgens**()
Schedule all currently open *asynchronous generator* objects to close with an `aclose()` call. After calling this method, the event loop will issue a warning whenever a new asynchronous generator is iterated. Should be used to finalize all scheduled asynchronous generators reliably. Example:

```
try:
    loop.run_forever()
finally:
    loop.run_until_complete(loop.shutdown_asyncgens())
    loop.close()
```

New in version 3.6.

Calls

Most *asyncio* functions don't accept keywords. If you want to pass keywords to your callback, use *functools.partial()*. For example, `loop.call_soon(functools.partial(print, "Hello", flush=True))` will call `print("Hello", flush=True)`.

Note: *functools.partial()* is better than `lambda` functions, because *asyncio* can inspect *functools.partial()* object to display parameters in debug mode, whereas `lambda` functions have a poor representation.

AbstractEventLoop.**call_soon**(*callback*, **args*, *context=None*)
Arrange for a callback to be called as soon as possible. The callback is called after *call_soon()* returns, when control returns to the event loop.

This operates as a FIFO queue, callbacks are called in the order in which they are registered. Each callback will be called exactly once.

Any positional arguments after the callback will be passed to the callback when it is called.

An optional keyword-only *context* argument allows specifying a custom *contextvars.Context* for the *callback* to run in. The current context is used when no *context* is provided.

An instance of *asyncio.Handle* is returned, which can be used to cancel the callback.

Use functools.partial to pass keywords to the callback.

Changed in version 3.7: The *context* keyword-only parameter was added. See **PEP 567** for more details.

AbstractEventLoop.**call_soon_threadsafe**(*callback*, **args*, *context=None*)
Like *call_soon()*, but thread safe.

See the *concurrency and multithreading* section of the documentation.

Changed in version 3.7: The *context* keyword-only parameter was added. See **PEP 567** for more details.

Delayed calls

The event loop has its own internal clock for computing timeouts. Which clock is used depends on the (platform-specific) event loop implementation; ideally it is a monotonic clock. This will generally be a different clock than *time.time()*.

Note: Timeouts (relative *delay* or absolute *when*) should not exceed one day.

`AbstractEventLoop.call_later(`*delay*, *callback*, **args*, *context=None*`)`
Arrange for the *callback* to be called after the given *delay* seconds (either an int or float).

An instance of *asyncio.TimerHandle* is returned, which can be used to cancel the callback.

callback will be called exactly once per call to *call_later()*. If two callbacks are scheduled for exactly the same time, it is undefined which will be called first.

The optional positional *args* will be passed to the callback when it is called. If you want the callback to be called with some named arguments, use a closure or *functools.partial()*.

An optional keyword-only *context* argument allows specifying a custom *contextvars.Context* for the *callback* to run in. The current context is used when no *context* is provided.

Use functools.partial to pass keywords to the callback.

Changed in version 3.7: The *context* keyword-only parameter was added. See **PEP 567** for more details.

`AbstractEventLoop.call_at(`*when*, *callback*, **args*, *context=None*`)`
Arrange for the *callback* to be called at the given absolute timestamp *when* (an int or float), using the same time reference as *AbstractEventLoop.time()*.

This method's behavior is the same as *call_later()*.

An instance of *asyncio.TimerHandle* is returned, which can be used to cancel the callback.

Use functools.partial to pass keywords to the callback.

Changed in version 3.7: The *context* keyword-only parameter was added. See **PEP 567** for more details.

`AbstractEventLoop.time()`
Return the current time, as a *float* value, according to the event loop's internal clock.

See also:

The *asyncio.sleep()* function.

Futures

`AbstractEventLoop.create_future()`
Create an *asyncio.Future* object attached to the loop.

This is a preferred way to create futures in asyncio, as event loop implementations can provide alternative implementations of the Future class (with better performance or instrumentation).

New in version 3.5.2.

Tasks

`AbstractEventLoop.create_task(`*coro*`)`
Schedule the execution of a *coroutine object*: wrap it in a future. Return a *Task* object.

Third-party event loops can use their own subclass of *Task* for interoperability. In this case, the result type is a subclass of *Task*.

New in version 3.4.2.

`AbstractEventLoop.set_task_factory(`*factory*`)`
Set a task factory that will be used by *AbstractEventLoop.create_task()*.

If *factory* is `None` the default task factory will be set.

If *factory* is a *callable*, it should have a signature matching `(loop, coro)`, where *loop* will be a reference to the active event loop, *coro* will be a coroutine object. The callable must return an *asyncio.Future* compatible object.

New in version 3.4.4.

`AbstractEventLoop.get_task_factory()`
Return a task factory, or `None` if the default one is in use.

New in version 3.4.4.

Creating connections

`coroutine AbstractEventLoop.create_connection(`*protocol_factory*, *host=None*, *port=None*, ***, *ssl=None*, *family=0*, *proto=0*, *flags=0*, *sock=None*, *local_addr=None*, *server_hostname=None*, *ssl_handshake_timeout=None*`)`

Create a streaming transport connection to a given Internet *host* and *port*: socket family *AF_INET* or *AF_INET6* depending on *host* (or *family* if specified), socket type *SOCK_STREAM*. *protocol_factory* must be a callable returning a *protocol* instance.

This method will try to establish the connection in the background. When successful, it returns a `(transport, protocol)` pair.

The chronological synopsis of the underlying operation is as follows:

1. The connection is established, and a *transport* is created to represent it.
2. *protocol_factory* is called without arguments and must return a *protocol* instance.
3. The protocol instance is tied to the transport, and its `connection_made()` method is called.
4. The coroutine returns successfully with the `(transport, protocol)` pair.

The created transport is an implementation-dependent bidirectional stream.

Note: *protocol_factory* can be any kind of callable, not necessarily a class. For example, if you want to use a pre-created protocol instance, you can pass `lambda: my_protocol`.

Options that change how the connection is created:

- *ssl*: if given and not false, a SSL/TLS transport is created (by default a plain TCP transport is created). If *ssl* is a *ssl.SSLContext* object, this context is used to create the transport; if *ssl* is *True*, a context with some unspecified default settings is used.

  See also:

  SSL/TLS security considerations

- *server_hostname*, is only for use together with *ssl*, and sets or overrides the hostname that the target server's certificate will be matched against. By default the value of the *host* argument is used. If *host* is empty, there is no default and you must pass a value for *server_hostname*. If *server_hostname* is an empty string, hostname matching is disabled (which is a serious security risk, allowing for man-in-the-middle-attacks).
- *family*, *proto*, *flags* are the optional address family, protocol and flags to be passed through to getaddrinfo() for *host* resolution. If given, these should all be integers from the corresponding *socket* module constants.

- *sock*, if given, should be an existing, already connected *socket.socket* object to be used by the transport. If *sock* is given, none of *host*, *port*, *family*, *proto*, *flags* and *local_addr* should be specified.
- *local_addr*, if given, is a `(local_host, local_port)` tuple used to bind the socket to locally. The *local_host* and *local_port* are looked up using getaddrinfo(), similarly to *host* and *port*.
- *ssl_handshake_timeout* is (for an SSL connection) the time in seconds to wait for the SSL handshake to complete before aborting the connection. `60.0` seconds if `None` (default).

New in version 3.7: The *ssl_handshake_timeout* parameter.

Changed in version 3.5: On Windows with *ProactorEventLoop*, SSL/TLS is now supported.

See also:

The *open_connection()* function can be used to get a pair of (*StreamReader*, *StreamWriter*) instead of a protocol.

`coroutine AbstractEventLoop.create_datagram_endpoint(`*protocol_factory*, *local_addr=None*, *remote_addr=None*, ***, *family=0*, *proto=0*, *flags=0*, *reuse_address=None*, *reuse_port=None*, *allow_broadcast=None*, *sock=None*`)`

Create datagram connection: socket family *AF_INET*, *AF_INET6* or *AF_UNIX* depending on *host* (or *family* if specified), socket type *SOCK_DGRAM*. *protocol_factory* must be a callable returning a *protocol* instance.

This method will try to establish the connection in the background. When successful, it returns a `(transport, protocol)` pair.

Options changing how the connection is created:

- *local_addr*, if given, is a `(local_host, local_port)` tuple used to bind the socket to locally. The *local_host* and *local_port* are looked up using *getaddrinfo()*.
- *remote_addr*, if given, is a `(remote_host, remote_port)` tuple used to connect the socket to a remote address. The *remote_host* and *remote_port* are looked up using *getaddrinfo()*.
- *family*, *proto*, *flags* are the optional address family, protocol and flags to be passed through to *getaddrinfo()* for *host* resolution. If given, these should all be integers from the corresponding *socket* module constants.
- *reuse_address* tells the kernel to reuse a local socket in TIME_WAIT state, without waiting for its natural timeout to expire. If not specified will automatically be set to `True` on UNIX.
- *reuse_port* tells the kernel to allow this endpoint to be bound to the same port as other existing endpoints are bound to, so long as they all set this flag when being created. This option is not supported on Windows and some UNIX's. If the `SO_REUSEPORT` constant is not defined then this capability is unsupported.
- *allow_broadcast* tells the kernel to allow this endpoint to send messages to the broadcast address.
- *sock* can optionally be specified in order to use a preexisting, already connected, *socket.socket* object to be used by the transport. If specified, *local_addr* and *remote_addr* should be omitted (must be *None*).

On Windows with *ProactorEventLoop*, this method is not supported.

See *UDP echo client protocol* and *UDP echo server protocol* examples.

Changed in version 3.4.4: The *family*, *proto*, *flags*, *reuse_address*, *reuse_port, *allow_broadcast*, and *sock* parameters were added.

coroutine AbstractEventLoop.create_unix_connection(*protocol_factory*, *path=None*, ***, *ssl=None*, *sock=None*, *server_hostname=None*, *ssl_handshake_timeout=None*)

Create UNIX connection: socket family *AF_UNIX*, socket type *SOCK_STREAM*. The *AF_UNIX* socket family is used to communicate between processes on the same machine efficiently.

This method will try to establish the connection in the background. When successful, it returns a `(transport, protocol)` pair.

path is the name of a UNIX domain socket, and is required unless a *sock* parameter is specified. Abstract UNIX sockets, *str*, *bytes*, and *Path* paths are supported.

See the *AbstractEventLoop.create_connection()* method for parameters.

Availability: UNIX.

New in version 3.7: The *ssl_handshake_timeout* parameter.

Changed in version 3.7: The *path* parameter can now be a *path-like object*.

Creating listening connections

coroutine AbstractEventLoop.create_server(*protocol_factory*, *host=None*, *port=None*, ***, *family=socket.AF_UNSPEC*, *flags=socket.AI_PASSIVE*, *sock=None*, *backlog=100*, *ssl=None*, *reuse_address=None*, *reuse_port=None*, *ssl_handshake_timeout=None*, *start_serving=True*)

Create a TCP server (socket type *SOCK_STREAM*) bound to *host* and *port*.

Return a *Server* object, its *sockets* attribute contains created sockets. Use the *Server.close()* method to stop the server: close listening sockets.

Parameters:

- The *host* parameter can be a string, in that case the TCP server is bound to *host* and *port*. The *host* parameter can also be a sequence of strings and in that case the TCP server is bound to all hosts of the sequence. If *host* is an empty string or `None`, all interfaces are assumed and a list of multiple sockets will be returned (most likely one for IPv4 and another one for IPv6).
- *family* can be set to either *socket.AF_INET* or *AF_INET6* to force the socket to use IPv4 or IPv6. If not set it will be determined from host (defaults to `socket.AF_UNSPEC`).
- *flags* is a bitmask for *getaddrinfo()*.
- *sock* can optionally be specified in order to use a preexisting socket object. If specified, *host* and *port* should be omitted (must be *None*).
- *backlog* is the maximum number of queued connections passed to *listen()* (defaults to 100).
- *ssl* can be set to an *SSLContext* to enable SSL over the accepted connections.
- *reuse_address* tells the kernel to reuse a local socket in TIME_WAIT state, without waiting for its natural timeout to expire. If not specified will automatically be set to `True` on UNIX.
- *reuse_port* tells the kernel to allow this endpoint to be bound to the same port as other existing endpoints are bound to, so long as they all set this flag when being created. This option is not supported on Windows.
- *ssl_handshake_timeout* is (for an SSL server) the time in seconds to wait for the SSL handshake to complete before aborting the connection. `60.0` seconds if `None` (default).

- *start_serving* set to `True` (the default) causes the created server to start accepting connections immediately. When set to `False`, the user should await on *Server.start_serving()* or *Server.serve_forever()* to make the server to start accepting connections.

New in version 3.7: *ssl_handshake_timeout* and *start_serving* parameters.

Changed in version 3.5: On Windows with *ProactorEventLoop*, SSL/TLS is now supported.

See also:

The function *start_server()* creates a (*StreamReader*, *StreamWriter*) pair and calls back a function with this pair.

Changed in version 3.5.1: The *host* parameter can now be a sequence of strings.

coroutine AbstractEventLoop.**create_unix_server**(*protocol_factory*, *path=None*, ***, *sock=None*, *backlog=100*, *ssl=None*, *ssl_handshake_timeout=None*, *start_serving=True*)

Similar to *AbstractEventLoop.create_server()*, but specific to the socket family *AF_UNIX*.

path is the name of a UNIX domain socket, and is required unless a *sock* parameter is specified. Abstract UNIX sockets, *str*, *bytes*, and *Path* paths are supported.

Availability: UNIX.

New in version 3.7: The *ssl_handshake_timeout* and *start_serving* parameters.

Changed in version 3.7: The *path* parameter can now be a *Path* object.

coroutine BaseEventLoop.**connect_accepted_socket**(*protocol_factory*, *sock*, ***, *ssl=None*, *ssl_handshake_timeout=None*)

Handle an accepted connection.

This is used by servers that accept connections outside of asyncio but that use asyncio to handle them.

Parameters:

- *sock* is a preexisting socket object returned from an `accept` call.
- *ssl* can be set to an *SSLContext* to enable SSL over the accepted connections.
- *ssl_handshake_timeout* is (for an SSL connection) the time in seconds to wait for the SSL handshake to complete before aborting the connection. `60.0` seconds if `None` (default).

When completed it returns a `(transport, protocol)` pair.

New in version 3.7: The *ssl_handshake_timeout* parameter.

New in version 3.5.3.

File Transferring

coroutine AbstractEventLoop.**sendfile**(*transport*, *file*, *offset=0*, *count=None*, ***, *fallback=True*)

Send a *file* to *transport*, return the total number of bytes which were sent.

The method uses high-performance *os.sendfile()* if available.

file must be a regular file object opened in binary mode.

offset tells from where to start reading the file. If specified, *count* is the total number of bytes to transmit as opposed to sending the file until EOF is reached. File position is updated on return or also in case of error in which case *file.tell()* can be used to figure out the number of bytes which were sent.

fallback set to `True` makes asyncio to manually read and send the file when the platform does not support the sendfile syscall (e.g. Windows or SSL socket on Unix).

Raise *SendfileNotAvailableError* if the system does not support *sendfile* syscall and *fallback* is `False`.

New in version 3.7.

TLS Upgrade

coroutine AbstractEventLoop.**start_tls**(*transport*, *protocol*, *sslcontext*, ***, *server_side=False*, *server_hostname=None*, *ssl_handshake_timeout=None*)

Upgrades an existing connection to TLS.

Returns a new transport instance, that the *protocol* must start using immediately after the *await*. The *transport* instance passed to the *start_tls* method should never be used again.

Parameters:

- *transport* and *protocol* instances that methods like *create_server()* and *create_connection()* return.
- *sslcontext*: a configured instance of *SSLContext*.
- *server_side* pass `True` when a server-side connection is being upgraded (like the one created by *create_server()*).
- *server_hostname*: sets or overrides the host name that the target server's certificate will be matched against.
- *ssl_handshake_timeout* is (for an SSL connection) the time in seconds to wait for the SSL handshake to complete before aborting the connection. `60.0` seconds if `None` (default).

New in version 3.7.

Watch file descriptors

On Windows with *SelectorEventLoop*, only socket handles are supported (ex: pipe file descriptors are not supported).

On Windows with *ProactorEventLoop*, these methods are not supported.

AbstractEventLoop.**add_reader**(*fd*, *callback*, **args*)

Start watching the file descriptor for read availability and then call the *callback* with specified arguments.

Use functools.partial to pass keywords to the callback.

AbstractEventLoop.**remove_reader**(*fd*)

Stop watching the file descriptor for read availability.

AbstractEventLoop.**add_writer**(*fd*, *callback*, **args*)

Start watching the file descriptor for write availability and then call the *callback* with specified arguments.

Use functools.partial to pass keywords to the callback.

AbstractEventLoop.**remove_writer**(*fd*)

Stop watching the file descriptor for write availability.

The *watch a file descriptor for read events* example uses the low-level *AbstractEventLoop.add_reader()* method to register the file descriptor of a socket.

Low-level socket operations

coroutine AbstractEventLoop.**sock_recv**(*sock*, *nbytes*)
Receive data from the socket. Modeled after blocking *socket.socket.recv()* method.

The return value is a bytes object representing the data received. The maximum amount of data to be received at once is specified by *nbytes*.

With *SelectorEventLoop* event loop, the socket *sock* must be non-blocking.

Changed in version 3.7: Even though the method was always documented as a coroutine method, before Python 3.7 it returned a *Future*. Since Python 3.7, this is an `async def` method.

coroutine AbstractEventLoop.**sock_recv_into**(*sock*, *buf*)
Receive data from the socket. Modeled after blocking *socket.socket.recv_into()* method.

The received data is written into *buf* (a writable buffer). The return value is the number of bytes written.

With *SelectorEventLoop* event loop, the socket *sock* must be non-blocking.

New in version 3.7.

coroutine AbstractEventLoop.**sock_sendall**(*sock*, *data*)
Send data to the socket. Modeled after blocking *socket.socket.sendall()* method.

The socket must be connected to a remote socket. This method continues to send data from *data* until either all data has been sent or an error occurs. `None` is returned on success. On error, an exception is raised, and there is no way to determine how much data, if any, was successfully processed by the receiving end of the connection.

With *SelectorEventLoop* event loop, the socket *sock* must be non-blocking.

Changed in version 3.7: Even though the method was always documented as a coroutine method, before Python 3.7 it returned an *Future*. Since Python 3.7, this is an `async def` method.

coroutine AbstractEventLoop.**sock_connect**(*sock*, *address*)
Connect to a remote socket at *address*. Modeled after blocking *socket.socket.connect()* method.

With *SelectorEventLoop* event loop, the socket *sock* must be non-blocking.

Changed in version 3.5.2: `address` no longer needs to be resolved. `sock_connect` will try to check if the *address* is already resolved by calling *socket.inet_pton()*. If not, *AbstractEventLoop.getaddrinfo()* will be used to resolve the *address*.

See also:

AbstractEventLoop.create_connection() and *asyncio.open_connection()*.

coroutine AbstractEventLoop.**sock_accept**(*sock*)
Accept a connection. Modeled after blocking *socket.socket.accept()*.

The socket must be bound to an address and listening for connections. The return value is a pair `(conn, address)` where *conn* is a *new* socket object usable to send and receive data on the connection, and *address* is the address bound to the socket on the other end of the connection.

The socket *sock* must be non-blocking.

Changed in version 3.7: Even though the method was always documented as a coroutine method, before Python 3.7 it returned a *Future*. Since Python 3.7, this is an `async def` method.

See also:

AbstractEventLoop.create_server() and *start_server()*.

coroutine AbstractEventLoop.**sock_sendfile**(*sock*, *file*, *offset=0*, *count=None*, ***, *fallback=True*)
Send a file using high-performance *os.sendfile* if possible and return the total number of bytes which were sent.

Asynchronous version of *socket.socket.sendfile()*.

sock must be non-blocking *socket* of *socket.SOCK_STREAM* type.

file must be a regular file object opened in binary mode.

offset tells from where to start reading the file. If specified, *count* is the total number of bytes to transmit as opposed to sending the file until EOF is reached. File position is updated on return or also in case of error in which case *file.tell()* can be used to figure out the number of bytes which were sent.

fallback set to `True` makes asyncio to manually read and send the file when the platform does not support the sendfile syscall (e.g. Windows or SSL socket on Unix).

Raise *SendfileNotAvailableError* if the system does not support *sendfile* syscall and *fallback* is `False`.

New in version 3.7.

Resolve host name

coroutine AbstractEventLoop.**getaddrinfo**(*host*, *port*, ***, *family=0*, *type=0*, *proto=0*, *flags=0*)
This method is a *coroutine*, similar to *socket.getaddrinfo()* function but non-blocking.

coroutine AbstractEventLoop.**getnameinfo**(*sockaddr*, *flags=0*)
This method is a *coroutine*, similar to *socket.getnameinfo()* function but non-blocking.

Changed in version 3.7: Both *getaddrinfo* and *getnameinfo* methods were always documented to return a coroutine, but prior to Python 3.7 they were, in fact, returning *asyncio.Future* objects. Starting with Python 3.7 both methods are coroutines.

Connect pipes

On Windows with *SelectorEventLoop*, these methods are not supported. Use *ProactorEventLoop* to support pipes on Windows.

coroutine AbstractEventLoop.**connect_read_pipe**(*protocol_factory*, *pipe*)
Register read pipe in eventloop.

protocol_factory should instantiate object with *Protocol* interface. *pipe* is a *file-like object*. Return pair `(transport, protocol)`, where *transport* supports the *ReadTransport* interface.

With *SelectorEventLoop* event loop, the *pipe* is set to non-blocking mode.

coroutine AbstractEventLoop.**connect_write_pipe**(*protocol_factory*, *pipe*)
Register write pipe in eventloop.

protocol_factory should instantiate object with `BaseProtocol` interface. *pipe* is *file-like object*. Return pair `(transport, protocol)`, where *transport* supports *WriteTransport* interface.

With *SelectorEventLoop* event loop, the *pipe* is set to non-blocking mode.

See also:

The *AbstractEventLoop.subprocess_exec()* and *AbstractEventLoop.subprocess_shell()* methods.

UNIX signals

Availability: UNIX only.

`AbstractEventLoop.add_signal_handler(signum, callback, *args)`
Add a handler for a signal.

Raise *ValueError* if the signal number is invalid or uncatchable. Raise *RuntimeError* if there is a problem setting up the handler.

Use functools.partial to pass keywords to the callback.

`AbstractEventLoop.remove_signal_handler(sig)`
Remove a handler for a signal.

Return `True` if a signal handler was removed, `False` if not.

See also:

The *signal* module.

Executor

Call a function in an *Executor* (pool of threads or pool of processes). By default, an event loop uses a thread pool executor (*ThreadPoolExecutor*).

`AbstractEventLoop.run_in_executor(executor, func, *args)`
Arrange for a *func* to be called in the specified executor.

The *executor* argument should be an *Executor* instance. The default executor is used if *executor* is `None`.

*Use functools.partial to pass keywords to the *func*.*

This method returns a *asyncio.Future* object.

Changed in version 3.5.3: `BaseEventLoop.run_in_executor()` no longer configures the `max_workers` of the thread pool executor it creates, instead leaving it up to the thread pool executor (*ThreadPoolExecutor*) to set the default.

`AbstractEventLoop.set_default_executor(executor)`
Set the default executor used by *run_in_executor()*.

Error Handling API

Allows customizing how exceptions are handled in the event loop.

`AbstractEventLoop.set_exception_handler(handler)`
Set *handler* as the new event loop exception handler.

If *handler* is `None`, the default exception handler will be set.

If *handler* is a callable object, it should have a matching signature to `(loop, context)`, where `loop` will be a reference to the active event loop, `context` will be a `dict` object (see *call_exception_handler()* documentation for details about context).

`AbstractEventLoop.get_exception_handler()`
Return the exception handler, or `None` if the default one is in use.

New in version 3.5.2.

`AbstractEventLoop.default_exception_handler(context)`
Default exception handler.

This is called when an exception occurs and no exception handler is set, and can be called by a custom exception handler that wants to defer to the default behavior.

context parameter has the same meaning as in *call_exception_handler()*.

`AbstractEventLoop.call_exception_handler(context)`
Call the current event loop exception handler.

context is a `dict` object containing the following keys (new keys may be introduced later):

- 'message': Error message;
- 'exception' (optional): Exception object;
- 'future' (optional): *asyncio.Future* instance;
- 'handle' (optional): *asyncio.Handle* instance;
- 'protocol' (optional): *Protocol* instance;
- 'transport' (optional): *Transport* instance;
- 'socket' (optional): *socket.socket* instance.

Note: Note: this method should not be overloaded in subclassed event loops. For any custom exception handling, use *set_exception_handler()* method.

Debug mode

`AbstractEventLoop.get_debug()`
Get the debug mode (*bool*) of the event loop.

The default value is `True` if the environment variable `PYTHONASYNCIODEBUG` is set to a non-empty string, `False` otherwise.

New in version 3.4.2.

`AbstractEventLoop.set_debug(enabled: bool)`
Set the debug mode of the event loop.

New in version 3.4.2.

See also:

The *debug mode of asyncio*.

Server

`class asyncio.Server`
Server listening on sockets.

Object created by *AbstractEventLoop.create_server()*, *AbstractEventLoop.create_unix_server()*, *start_server()*, and *start_unix_server()* functions. Don't instantiate the class directly.

Server objects are asynchronous context managers. When used in an `async with` statement, it's guaranteed that the Server object is closed and not accepting new connections when the `async with` statement is completed:

```
srv = await loop.create_server(...)

async with srv:
    # some code

# At this point, srv is closed and no longer accepts new connections.
```

Changed in version 3.7: Server object is an asynchronous context manager since Python 3.7.

close()
Stop serving: close listening sockets and set the *sockets* attribute to `None`.

The sockets that represent existing incoming client connections are left open.

The server is closed asynchronously, use the *wait_closed()* coroutine to wait until the server is closed.

get_loop()
Gives the event loop associated with the server object.

New in version 3.7.

coroutine start_serving()
Start accepting connections.

This method is idempotent, so it can be called when the server is already being serving.

The new *start_serving* keyword-only parameter to *AbstractEventLoop.create_server()* and *asyncio.start_server()* allows to create a Server object that is not accepting connections right away. In which case this method, or *Server.serve_forever()* can be used to make the Server object to start accepting connections.

New in version 3.7.

coroutine serve_forever()
Start accepting connections until the coroutine is cancelled. Cancellation of `serve_forever` task causes the server to be closed.

This method can be called if the server is already accepting connections. Only one `serve_forever` task can exist per one *Server* object.

Example:

```
async def client_connected(reader, writer):
    # Communicate with the client with
    # reader/writer streams.  For example:
    await reader.readline()

async def main(host, port):
    srv = await asyncio.start_server(
        client_connected, host, port)
    await srv.serve_forever()

asyncio.run(main('127.0.0.1', 0))
```

New in version 3.7.

is_serving()
Return `True` if the server is accepting new connections.

New in version 3.7.

coroutine wait_closed()
Wait until the *close()* method completes.

sockets
List of *socket.socket* objects the server is listening to, or `None` if the server is closed.

Changed in version 3.7: Prior to Python 3.7 `Server.sockets` used to return the internal list of server's sockets directly. In 3.7 a copy of that list is returned.

Handle

class asyncio.Handle
A callback wrapper object returned by *AbstractEventLoop.call_soon()*, *AbstractEventLoop.call_soon_threadsafe()*.

cancel()
Cancel the call. If the callback is already canceled or executed, this method has no effect.

cancelled()
Return `True` if the call was cancelled.

New in version 3.7.

class asyncio.TimerHandle
A callback wrapper object returned by *AbstractEventLoop.call_later()*, and *AbstractEventLoop.call_at()*.

The class is inherited from *Handle*.

when()
Return a scheduled callback time as *float* seconds.

The time is an absolute timestamp, using the same time reference as *AbstractEventLoop.time()*.

New in version 3.7.

SendfileNotAvailableError

exception asyncio.SendfileNotAvailableError
Sendfile syscall is not available, subclass of *RuntimeError*.

Raised if the OS does not support sendfile syscall for given socket or file type.

Event loop examples

Hello World with call_soon()

Example using the *AbstractEventLoop.call_soon()* method to schedule a callback. The callback displays `"Hello World"` and then stops the event loop:

```
import asyncio

def hello_world(loop):
    print('Hello World')
    loop.stop()

loop = asyncio.get_event_loop()

# Schedule a call to hello_world()
loop.call_soon(hello_world, loop)
```

(continues on next page)

(continued from previous page)

```
# Blocking call interrupted by loop.stop()
loop.run_forever()
loop.close()
```

See also:

The *Hello World coroutine* example uses a *coroutine*.

Display the current date with call_later()

Example of callback displaying the current date every second. The callback uses the *AbstractEventLoop.call_later()* method to reschedule itself during 5 seconds, and then stops the event loop:

```
import asyncio
import datetime

def display_date(end_time, loop):
    print(datetime.datetime.now())
    if (loop.time() + 1.0) < end_time:
        loop.call_later(1, display_date, end_time, loop)
    else:
        loop.stop()

loop = asyncio.get_event_loop()

# Schedule the first call to display_date()
end_time = loop.time() + 5.0
loop.call_soon(display_date, end_time, loop)

# Blocking call interrupted by loop.stop()
loop.run_forever()
loop.close()
```

See also:

The *coroutine displaying the current date* example uses a *coroutine*.

Watch a file descriptor for read events

Wait until a file descriptor received some data using the *AbstractEventLoop.add_reader()* method and then close the event loop:

```
import asyncio
from socket import socketpair

# Create a pair of connected file descriptors
rsock, wsock = socketpair()
loop = asyncio.get_event_loop()

def reader():
    data = rsock.recv(100)
    print("Received:", data.decode())
    # We are done: unregister the file descriptor
    loop.remove_reader(rsock)
    # Stop the event loop
```

(continues on next page)

(continued from previous page)

```
    loop.stop()

# Register the file descriptor for read event
loop.add_reader(rsock, reader)

# Simulate the reception of data from the network
loop.call_soon(wsock.send, 'abc'.encode())

# Run the event loop
loop.run_forever()

# We are done, close sockets and the event loop
rsock.close()
wsock.close()
loop.close()
```

See also:

The *register an open socket to wait for data using a protocol* example uses a low-level protocol created by the *AbstractEventLoop.create_connection()* method.

The *register an open socket to wait for data using streams* example uses high-level streams created by the *open_connection()* function in a coroutine.

Set signal handlers for SIGINT and SIGTERM

Register handlers for signals `SIGINT` and `SIGTERM` using the *AbstractEventLoop.add_signal_handler()* method:

```
import asyncio
import functools
import os
import signal

def ask_exit(signame):
    print("got signal %s: exit" % signame)
    loop.stop()

loop = asyncio.get_event_loop()
for signame in ('SIGINT', 'SIGTERM'):
    loop.add_signal_handler(getattr(signal, signame),
                            functools.partial(ask_exit, signame))

print("Event loop running forever, press Ctrl+C to interrupt.")
print("pid %s: send SIGINT or SIGTERM to exit." % os.getpid())
try:
    loop.run_forever()
finally:
    loop.close()
```

This example only works on UNIX.

19.5.2 Event loops

Source code: Lib/asyncio/events.py

Event loop functions

The following functions are convenient shortcuts to accessing the methods of the global policy. Note that this provides access to the default policy, unless an alternative policy was set by calling *set_event_loop_policy()* earlier in the execution of the process.

asyncio.get_event_loop()
Equivalent to calling `get_event_loop_policy().get_event_loop()`.

asyncio.set_event_loop(*loop*)
Equivalent to calling `get_event_loop_policy().set_event_loop(loop)`.

asyncio.new_event_loop()
Equivalent to calling `get_event_loop_policy().new_event_loop()`.

asyncio.get_running_loop()
Return the running event loop in the current OS thread. If there is no running event loop a *RuntimeError* is raised.

New in version 3.7.

Available event loops

asyncio currently provides two implementations of event loops: *SelectorEventLoop* and *ProactorEventLoop*.

class asyncio.SelectorEventLoop
Event loop based on the *selectors* module. Subclass of *AbstractEventLoop*.

Use the most efficient selector available on the platform.

On Windows, only sockets are supported (ex: pipes are not supported): see the MSDN documentation of select.

class asyncio.ProactorEventLoop
Proactor event loop for Windows using "I/O Completion Ports" aka IOCP. Subclass of *AbstractEventLoop*.

Availability: Windows.

See also:

MSDN documentation on I/O Completion Ports.

Example to use a *ProactorEventLoop* on Windows:

```
import asyncio, sys

if sys.platform == 'win32':
    loop = asyncio.ProactorEventLoop()
    asyncio.set_event_loop(loop)
```

Platform support

The *asyncio* module has been designed to be portable, but each platform still has subtle differences and may not support all *asyncio* features.

Windows

Common limits of Windows event loops:

- *create_unix_connection()* and *create_unix_server()* are not supported: the socket family *socket.AF_UNIX* is specific to UNIX
- *add_signal_handler()* and *remove_signal_handler()* are not supported
- `EventLoopPolicy.set_child_watcher()` is not supported. *ProactorEventLoop* supports subprocesses. It has only one implementation to watch child processes, there is no need to configure it.

SelectorEventLoop specific limits:

- *SelectSelector* is used which only supports sockets and is limited to 512 sockets.
- *add_reader()* and *add_writer()* only accept file descriptors of sockets
- Pipes are not supported (ex: *connect_read_pipe()*, *connect_write_pipe()*)
- *Subprocesses* are not supported (ex: *subprocess_exec()*, *subprocess_shell()*)

ProactorEventLoop specific limits:

- *create_datagram_endpoint()* (UDP) is not supported
- *add_reader()* and *add_writer()* are not supported

The resolution of the monotonic clock on Windows is usually around 15.6 msec. The best resolution is 0.5 msec. The resolution depends on the hardware (availability of HPET) and on the Windows configuration. See *asyncio delayed calls*.

Changed in version 3.5: *ProactorEventLoop* now supports SSL.

Mac OS X

Character devices like PTY are only well supported since Mavericks (Mac OS 10.9). They are not supported at all on Mac OS 10.5 and older.

On Mac OS 10.6, 10.7 and 10.8, the default event loop is *SelectorEventLoop* which uses *selectors.KqueueSelector*. *selectors.KqueueSelector* does not support character devices on these versions. The *SelectorEventLoop* can be used with *SelectSelector* or *PollSelector* to support character devices on these versions of Mac OS X. Example:

```
import asyncio
import selectors

selector = selectors.SelectSelector()
loop = asyncio.SelectorEventLoop(selector)
asyncio.set_event_loop(loop)
```

Event loop policies and the default policy

Event loop management is abstracted with a *policy* pattern, to provide maximal flexibility for custom platforms and frameworks. Throughout the execution of a process, a single global policy object manages the event loops available to the process based on the calling context. A policy is an object implementing the *AbstractEventLoopPolicy* interface.

For most users of *asyncio*, policies never have to be dealt with explicitly, since the default global policy is sufficient (see below).

The module-level functions *get_event_loop()* and *set_event_loop()* provide convenient access to event loops managed by the default policy.

Event loop policy interface

An event loop policy must implement the following interface:

class asyncio.AbstractEventLoopPolicy
Event loop policy.

get_event_loop()
Get the event loop for the current context.

Returns an event loop object implementing the *AbstractEventLoop* interface. In case called from coroutine, it returns the currently running event loop.

Raises an exception in case no event loop has been set for the current context and the current policy does not specify to create one. It must never return `None`.

Changed in version 3.6.

set_event_loop(*loop*)
Set the event loop for the current context to *loop*.

new_event_loop()
Create and return a new event loop object according to this policy's rules.

If there's need to set this loop as the event loop for the current context, *set_event_loop()* must be called explicitly.

The default policy defines context as the current thread, and manages an event loop per thread that interacts with *asyncio*. An exception to this rule happens when *get_event_loop()* is called from a running future/coroutine, in which case it will return the current loop running that future/coroutine.

If the current thread doesn't already have an event loop associated with it, the default policy's *get_event_loop()* method creates one when called from the main thread, but raises *RuntimeError* otherwise.

Access to the global loop policy

asyncio.get_event_loop_policy()
Get the current event loop policy.

asyncio.set_event_loop_policy(*policy*)
Set the current event loop policy. If *policy* is `None`, the default policy is restored.

Customizing the event loop policy

To implement a new event loop policy, it is recommended you subclass the concrete default event loop policy `DefaultEventLoopPolicy` and override the methods for which you want to change behavior, for example:

```
class MyEventLoopPolicy(asyncio.DefaultEventLoopPolicy):

    def get_event_loop(self):
        """Get the event loop.

        This may be None or an instance of EventLoop.
        """
        loop = super().get_event_loop()
```

(continues on next page)

(continued from previous page)

```
        # Do something with loop ...
        return loop

asyncio.set_event_loop_policy(MyEventLoopPolicy())
```

19.5.3 Tasks and coroutines

Source code: Lib/asyncio/tasks.py

Source code: Lib/asyncio/coroutines.py

Coroutines

Coroutines used with *asyncio* may be implemented using the `async def` statement, or by using *generators*. The `async def` type of coroutine was added in Python 3.5, and is recommended if there is no need to support older Python versions.

Generator-based coroutines should be decorated with *@asyncio.coroutine*, although this is not strictly enforced. The decorator enables compatibility with `async def` coroutines, and also serves as documentation. Generator-based coroutines use the `yield from` syntax introduced in **PEP 380**, instead of the original `yield` syntax.

The word "coroutine", like the word "generator", is used for two different (though related) concepts:

- The function that defines a coroutine (a function definition using `async def` or decorated with `@asyncio.coroutine`). If disambiguation is needed we will call this a *coroutine function* (*iscoroutinefunction()* returns `True`).
- The object obtained by calling a coroutine function. This object represents a computation or an I/O operation (usually a combination) that will complete eventually. If disambiguation is needed we will call it a *coroutine object* (*iscoroutine()* returns `True`).

Things a coroutine can do:

- `result = await future` or `result = yield from future` – suspends the coroutine until the future is done, then returns the future's result, or raises an exception, which will be propagated. (If the future is cancelled, it will raise a `CancelledError` exception.) Note that tasks are futures, and everything said about futures also applies to tasks.
- `result = await coroutine` or `result = yield from coroutine` – wait for another coroutine to produce a result (or raise an exception, which will be propagated). The `coroutine` expression must be a *call* to another coroutine.
- `return expression` – produce a result to the coroutine that is waiting for this one using `await` or `yield from`.
- `raise exception` – raise an exception in the coroutine that is waiting for this one using `await` or `yield from`.

Calling a coroutine does not start its code running – the coroutine object returned by the call doesn't do anything until you schedule its execution. There are two basic ways to start it running: call `await coroutine` or `yield from coroutine` from another coroutine (assuming the other coroutine is already running!), or schedule its execution using the *ensure_future()* function or the *AbstractEventLoop.create_task()* method.

Coroutines (and tasks) can only run when the event loop is running.

`@asyncio.coroutine`
Decorator to mark generator-based coroutines. This enables the generator use `yield from` to call `async def` coroutines, and also enables the generator to be called by `async def` coroutines, for instance using an `await` expression.

There is no need to decorate `async def` coroutines themselves.

If the generator is not yielded from before it is destroyed, an error message is logged. See *Detect coroutines never scheduled*.

Note: In this documentation, some methods are documented as coroutines, even if they are plain Python functions returning a *Future*. This is intentional to have a freedom of tweaking the implementation of these functions in the future. If such a function is needed to be used in a callback-style code, wrap its result with *ensure_future()*.

`asyncio.run(`*coro*, ***, *debug=False*`)`
This function runs the passed coroutine, taking care of managing the asyncio event loop and finalizing asynchronous generators.

This function cannot be called when another asyncio event loop is running in the same thread.

If debug is True, the event loop will be run in debug mode.

This function always creates a new event loop and closes it at the end. It should be used as a main entry point for asyncio programs, and should ideally only be called once.

New in version 3.7: **Important:** this has been been added to asyncio in Python 3.7 on a *provisional basis*.

Example: Hello World coroutine

Example of coroutine displaying `"Hello World"`:

```
import asyncio

async def hello_world():
    print("Hello World!")

asyncio.run(hello_world())
```

See also:

The *Hello World with call_soon()* example uses the *AbstractEventLoop.call_soon()* method to schedule a callback.

Example: Coroutine displaying the current date

Example of coroutine displaying the current date every second during 5 seconds using the *sleep()* function:

```
import asyncio
import datetime

async def display_date():
    loop = asyncio.get_running_loop()
    end_time = loop.time() + 5.0
    while True:
```

(continues on next page)

(continued from previous page)

```
        print(datetime.datetime.now())
        if (loop.time() + 1.0) >= end_time:
            break
        await asyncio.sleep(1)

asyncio.run(display_date())
```

See also:

The *display the current date with call_later()* example uses a callback with the *AbstractEventLoop.call_later()* method.

Example: Chain coroutines

Example chaining coroutines:

```
import asyncio

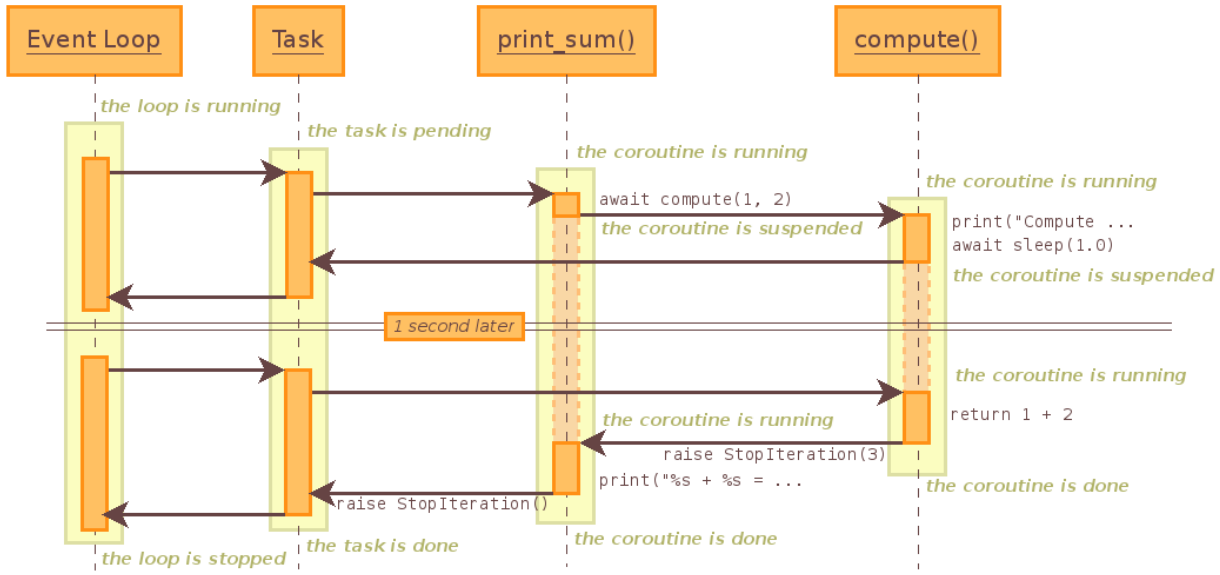
async def compute(x, y):
    print("Compute %s + %s ..." % (x, y))
    await asyncio.sleep(1.0)
    return x + y

async def print_sum(x, y):
    result = await compute(x, y)
    print("%s + %s = %s" % (x, y, result))

loop = asyncio.get_event_loop()
loop.run_until_complete(print_sum(1, 2))
loop.close()
```

`compute()` is chained to `print_sum()`: `print_sum()` coroutine waits until `compute()` is completed before returning its result.

Sequence diagram of the example:



The "Task" is created by the *AbstractEventLoop.run_until_complete()* method when it gets a coroutine object instead of a task.

The diagram shows the control flow, it does not describe exactly how things work internally. For example, the sleep coroutine creates an internal future which uses *AbstractEventLoop.call_later()* to wake up the task in 1 second.

InvalidStateError

exception asyncio.InvalidStateError
The operation is not allowed in this state.

TimeoutError

exception asyncio.TimeoutError
The operation exceeded the given deadline.

Note: This exception is different from the builtin *TimeoutError* exception!

Future

class asyncio.Future(*, *loop=None*)
This class is *almost* compatible with *concurrent.futures.Future*.

Differences:

- *result()* and *exception()* do not take a timeout argument and raise an exception when the future isn't done yet.
- Callbacks registered with *add_done_callback()* are always called via the event loop's *call_soon()*.
- This class is not compatible with the *wait()* and *as_completed()* functions in the *concurrent.futures* package.

This class is *not thread safe*.

cancel()
Cancel the future and schedule callbacks.

If the future is already done or cancelled, return `False`. Otherwise, change the future's state to cancelled, schedule the callbacks and return `True`.

cancelled()
Return `True` if the future was cancelled.

done()
Return `True` if the future is done.

Done means either that a result / exception are available, or that the future was cancelled.

result()
Return the result this future represents.

If the future has been cancelled, raises `CancelledError`. If the future's result isn't yet available, raises *InvalidStateError*. If the future is done and has an exception set, this exception is raised.

`exception()`
Return the exception that was set on this future.

The exception (or `None` if no exception was set) is returned only if the future is done. If the future has been cancelled, raises `CancelledError`. If the future isn't done yet, raises *InvalidStateError*.

`add_done_callback(`*callback*, *, *context=None*`)`
Add a callback to be run when the future becomes done.

The *callback* is called with a single argument - the future object. If the future is already done when this is called, the callback is scheduled with *call_soon()*.

An optional keyword-only *context* argument allows specifying a custom *contextvars.Context* for the *callback* to run in. The current context is used when no *context* is provided.

Use functools.partial to pass parameters to the callback. For example, `fut.add_done_callback(functools.partial(print, "Future:", flush=True))` will call `print("Future:", fut, flush=True)`.

Changed in version 3.7: The *context* keyword-only parameter was added. See **PEP 567** for more details.

`remove_done_callback(`*fn*`)`
Remove all instances of a callback from the "call when done" list.

Returns the number of callbacks removed.

`set_result(`*result*`)`
Mark the future done and set its result.

If the future is already done when this method is called, raises *InvalidStateError*.

`set_exception(`*exception*`)`
Mark the future done and set an exception.

If the future is already done when this method is called, raises *InvalidStateError*.

`get_loop()`
Return the event loop the future object is bound to.

New in version 3.7.

Example: Future with run_until_complete()

Example combining a *Future* and a *coroutine function*:

```
import asyncio

async def slow_operation(future):
    await asyncio.sleep(1)
    future.set_result('Future is done!')

loop = asyncio.get_event_loop()
future = asyncio.Future()
asyncio.ensure_future(slow_operation(future))
loop.run_until_complete(future)
print(future.result())
loop.close()
```

The coroutine function is responsible for the computation (which takes 1 second) and it stores the result into the future. The *run_until_complete()* method waits for the completion of the future.

Note: The *run_until_complete()* method uses internally the *add_done_callback()* method to be notified when the future is done.

Example: Future with run_forever()

The previous example can be written differently using the *Future.add_done_callback()* method to describe explicitly the control flow:

```
import asyncio

async def slow_operation(future):
    await asyncio.sleep(1)
    future.set_result('Future is done!')

def got_result(future):
    print(future.result())
    loop.stop()

loop = asyncio.get_event_loop()
future = asyncio.Future()
asyncio.ensure_future(slow_operation(future))
future.add_done_callback(got_result)
try:
    loop.run_forever()
finally:
    loop.close()
```

In this example, the future is used to link `slow_operation()` to `got_result()`: when `slow_operation()` is done, `got_result()` is called with the result.

Task

`asyncio.create_task(`*coro*`)`
Wrap a *coroutine* *coro* into a task and schedule its execution. Return the task object.

The task is executed in *get_running_loop()* context, *RuntimeError* is raised if there is no running loop in current thread.

New in version 3.7.

`class asyncio.Task(`*coro*, ***, *loop=None*`)`
A unit for concurrent running of *coroutines*, subclass of *Future*.

A task is responsible for executing a coroutine object in an event loop. If the wrapped coroutine yields from a future, the task suspends the execution of the wrapped coroutine and waits for the completion of the future. When the future is done, the execution of the wrapped coroutine restarts with the result or the exception of the future.

Event loops use cooperative scheduling: an event loop only runs one task at a time. Other tasks may run in parallel if other event loops are running in different threads. While a task waits for the completion of a future, the event loop executes a new task.

The cancellation of a task is different from the cancellation of a future. Calling *cancel()* will throw a *CancelledError* to the wrapped coroutine. *cancelled()* only returns `True` if the wrapped coroutine did not catch the *CancelledError* exception, or raised a *CancelledError* exception.

If a pending task is destroyed, the execution of its wrapped *coroutine* did not complete. It is probably a bug and a warning is logged: see *Pending task destroyed*.

Don't directly create *Task* instances: use the *create_task()* function or the *AbstractEventLoop.create_task()* method.

Tasks support the *contextvars* module. When a Task is created it copies the current context and later runs its coroutine in the copied context. See **PEP 567** for more details.

This class is *not thread safe*.

Changed in version 3.7: Added support for the *contextvars* module.

classmethod all_tasks(*loop=None*)
Return a set of all tasks for an event loop.

By default all tasks for the current event loop are returned. If *loop* is `None`, *get_event_loop()* function is used to get the current loop.

classmethod current_task(*loop=None*)
Return the currently running task in an event loop or `None`.

By default the current task for the current event loop is returned.

`None` is returned when called not in the context of a *Task*.

cancel()
Request that this task cancel itself.

This arranges for a *CancelledError* to be thrown into the wrapped coroutine on the next cycle through the event loop. The coroutine then has a chance to clean up or even deny the request using try/except/finally.

Unlike *Future.cancel()*, this does not guarantee that the task will be cancelled: the exception might be caught and acted upon, delaying cancellation of the task or preventing cancellation completely. The task may also return a value or raise a different exception.

Immediately after this method is called, *cancelled()* will not return `True` (unless the task was already cancelled). A task will be marked as cancelled when the wrapped coroutine terminates with a *CancelledError* exception (even if *cancel()* was not called).

get_stack(***, *limit=None*)
Return the list of stack frames for this task's coroutine.

If the coroutine is not done, this returns the stack where it is suspended. If the coroutine has completed successfully or was cancelled, this returns an empty list. If the coroutine was terminated by an exception, this returns the list of traceback frames.

The frames are always ordered from oldest to newest.

The optional limit gives the maximum number of frames to return; by default all available frames are returned. Its meaning differs depending on whether a stack or a traceback is returned: the newest frames of a stack are returned, but the oldest frames of a traceback are returned. (This matches the behavior of the traceback module.)

For reasons beyond our control, only one stack frame is returned for a suspended coroutine.

print_stack(***, *limit=None*, *file=None*)
Print the stack or traceback for this task's coroutine.

This produces output similar to that of the traceback module, for the frames retrieved by get_stack(). The limit argument is passed to get_stack(). The file argument is an I/O stream to which the output is written; by default output is written to sys.stderr.

Example: Parallel execution of tasks

Example executing 3 tasks (A, B, C) in parallel:

```
import asyncio

async def factorial(name, number):
    f = 1
    for i in range(2, number+1):
        print("Task %s: Compute factorial(%s)..." % (name, i))
        await asyncio.sleep(1)
        f *= i
    print("Task %s: factorial(%s) = %s" % (name, number, f))

loop = asyncio.get_event_loop()
loop.run_until_complete(asyncio.gather(
    factorial("A", 2),
    factorial("B", 3),
    factorial("C", 4),
))
loop.close()
```

Output:

```
Task A: Compute factorial(2)...
Task B: Compute factorial(2)...
Task C: Compute factorial(2)...
Task A: factorial(2) = 2
Task B: Compute factorial(3)...
Task C: Compute factorial(3)...
Task B: factorial(3) = 6
Task C: Compute factorial(4)...
Task C: factorial(4) = 24
```

A task is automatically scheduled for execution when it is created. The event loop stops when all tasks are done.

Task functions

Note: In the functions below, the optional *loop* argument allows explicitly setting the event loop object used by the underlying task or coroutine. If it's not provided, the default event loop is used.

`asyncio.current_task`(*loop=None*)

Return the current running *Task* instance or `None`, if no task is running.

If *loop* is `None` *get_running_loop()* is used to get the current loop.

New in version 3.7.

`asyncio.all_tasks`(*loop=None*)

Return a set of *Task* objects created for the loop.

If *loop* is `None`, *get_running_loop()* is used for getting current loop (contrary to the deprecated *Task.all_tasks()* method that uses *get_event_loop()*.)

New in version 3.7.

asyncio.**as_completed**(*fs*, ***, *loop=None*, *timeout=None*)
Return an iterator whose values, when waited for, are *Future* instances.

Raises *asyncio.TimeoutError* if the timeout occurs before all Futures are done.

Example:

```
for f in as_completed(fs):
    result = await f  # The 'await' may raise
    # Use result
```

Note: The futures `f` are not necessarily members of fs.

asyncio.**ensure_future**(*coro_or_future*, ***, *loop=None*)
Schedule the execution of a *coroutine object*: wrap it in a future. Return a *Task* object.

If the argument is a *Future*, it is returned directly.

New in version 3.4.4.

Changed in version 3.5.1: The function accepts any *awaitable* object.

Note: *create_task()* (added in Python 3.7) is the preferable way for spawning new tasks.

See also:

The *create_task()* function and *AbstractEventLoop.create_task()* method.

asyncio.**wrap_future**(*future*, ***, *loop=None*)
Wrap a *concurrent.futures.Future* object in a *Future* object.

asyncio.**gather**(**coros_or_futures*, *loop=None*, *return_exceptions=False*)
Return a future aggregating results from the given coroutine objects or futures.

All futures must share the same event loop. If all the tasks are done successfully, the returned future's result is the list of results (in the order of the original sequence, not necessarily the order of results arrival). If *return_exceptions* is true, exceptions in the tasks are treated the same as successful results, and gathered in the result list; otherwise, the first raised exception will be immediately propagated to the returned future.

Cancellation: if the outer Future is cancelled, all children (that have not completed yet) are also cancelled. If any child is cancelled, this is treated as if it raised *CancelledError* – the outer Future is *not* cancelled in this case. (This is to prevent the cancellation of one child to cause other children to be cancelled.)

Changed in version 3.7.0: If the *gather* itself is cancelled, the cancellation is propagated regardless of *return_exceptions*.

asyncio.**iscoroutine**(*obj*)
Return `True` if *obj* is a *coroutine object*, which may be based on a generator or an `async def` coroutine.

asyncio.**iscoroutinefunction**(*func*)
Return `True` if *func* is determined to be a *coroutine function*, which may be a decorated generator function or an `async def` function.

asyncio.**run_coroutine_threadsafe**(*coro*, *loop*)
Submit a *coroutine object* to a given event loop.

Return a *concurrent.futures.Future* to access the result.

This function is meant to be called from a different thread than the one where the event loop is running. Usage:

```
# Create a coroutine
coro = asyncio.sleep(1, result=3)
# Submit the coroutine to a given loop
future = asyncio.run_coroutine_threadsafe(coro, loop)
# Wait for the result with an optional timeout argument
assert future.result(timeout) == 3
```

If an exception is raised in the coroutine, the returned future will be notified. It can also be used to cancel the task in the event loop:

```
try:
    result = future.result(timeout)
except asyncio.TimeoutError:
    print('The coroutine took too long, cancelling the task...')
    future.cancel()
except Exception as exc:
    print('The coroutine raised an exception: {!r}'.format(exc))
else:
    print('The coroutine returned: {!r}'.format(result))
```

See the *concurrency and multithreading* section of the documentation.

Note: Unlike other functions from the module, *run_coroutine_threadsafe()* requires the *loop* argument to be passed explicitly.

New in version 3.5.1.

coroutine asyncio.sleep(*delay*, *result=None*, ***, *loop=None*)

Create a *coroutine* that completes after a given time (in seconds). If *result* is provided, it is produced to the caller when the coroutine completes.

The resolution of the sleep depends on the *granularity of the event loop*.

This function is a *coroutine*.

coroutine asyncio.shield(*arg*, ***, *loop=None*)

Wait for a future, shielding it from cancellation.

The statement:

```
res = await shield(something())
```

is exactly equivalent to the statement:

```
res = await something()
```

except that if the coroutine containing it is cancelled, the task running in `something()` is not cancelled. From the point of view of `something()`, the cancellation did not happen. But its caller is still cancelled, so the yield-from expression still raises *CancelledError*. Note: If `something()` is cancelled by other means this will still cancel `shield()`.

If you want to completely ignore cancellation (not recommended) you can combine `shield()` with a try/except clause, as follows:

```
try:
    res = await shield(something())
except CancelledError:
    res = None
```

coroutine asyncio.wait(*futures*, ***, *loop=None*, *timeout=None*, *return_when=ALL_COMPLETED*)

Wait for the Futures and coroutine objects given by the sequence *futures* to complete. Coroutines will be wrapped in Tasks. Returns two sets of *Future*: (done, pending).

The sequence *futures* must not be empty.

timeout can be used to control the maximum number of seconds to wait before returning. *timeout* can be an int or float. If *timeout* is not specified or `None`, there is no limit to the wait time.

return_when indicates when this function should return. It must be one of the following constants of the *concurrent.futures* module:

Constant	Description
`FIRST_COMPLETED`	The function will return when any future finishes or is cancelled.
`FIRST_EXCEPTION`	The function will return when any future finishes by raising an exception. If no future raises an exception then it is equivalent to `ALL_COMPLETED`.
`ALL_COMPLETED`	The function will return when all futures finish or are cancelled.

Unlike *wait_for()*, `wait()` will not cancel the futures when a timeout occurs.

This function is a *coroutine*.

Usage:

```
done, pending = await asyncio.wait(fs)
```

Note: This does not raise *asyncio.TimeoutError*! Futures that aren't done when the timeout occurs are returned in the second set.

coroutine asyncio.wait_for(*fut*, *timeout*, ***, *loop=None*)

Wait for the single *Future* or *coroutine object* to complete with timeout. If *timeout* is `None`, block until the future completes.

Coroutine will be wrapped in *Task*.

Returns result of the Future or coroutine. When a timeout occurs, it cancels the task and raises *asyncio.TimeoutError*. To avoid the task cancellation, wrap it in *shield()*. The function will wait until the future is actually cancelled, so the total wait time may exceed the *timeout*.

If the wait is cancelled, the future *fut* is also cancelled.

This function is a *coroutine*, usage:

```
result = await asyncio.wait_for(fut, 60.0)
```

Changed in version 3.4.3: If the wait is cancelled, the future *fut* is now also cancelled.

Changed in version 3.7: When *fut* is cancelled due to a timeout, `wait_for` now waits for *fut* to be cancelled. Previously, it raised *TimeoutError* immediately.

19.5.4 Transports and protocols (callback based API)

Source code: Lib/asyncio/transports.py

Source code: Lib/asyncio/protocols.py

Transports

Transports are classes provided by *asyncio* in order to abstract various kinds of communication channels. You generally won't instantiate a transport yourself; instead, you will call an *AbstractEventLoop* method which will create the transport and try to initiate the underlying communication channel, calling you back when it succeeds.

Once the communication channel is established, a transport is always paired with a *protocol* instance. The protocol can then call the transport's methods for various purposes.

asyncio currently implements transports for TCP, UDP, SSL, and subprocess pipes. The methods available on a transport depend on the transport's kind.

The transport classes are *not thread safe*.

Changed in version 3.6: The socket option `TCP_NODELAY` is now set by default.

BaseTransport

class asyncio.BaseTransport

Base class for transports.

close()

Close the transport. If the transport has a buffer for outgoing data, buffered data will be flushed asynchronously. No more data will be received. After all buffered data is flushed, the protocol's `connection_lost()` method will be called with *None* as its argument.

is_closing()

Return `True` if the transport is closing or is closed.

New in version 3.5.1.

get_extra_info(*name*, *default=None*)

Return optional transport information. *name* is a string representing the piece of transport-specific information to get, *default* is the value to return if the information doesn't exist.

This method allows transport implementations to easily expose channel-specific information.

- socket:
  - `'peername'`: the remote address to which the socket is connected, result of *socket.socket.getpeername()* (`None` on error)
  - `'socket'`: *socket.socket* instance
  - `'sockname'`: the socket's own address, result of *socket.socket.getsockname()*
- SSL socket:
  - `'compression'`: the compression algorithm being used as a string, or `None` if the connection isn't compressed; result of *ssl.SSLSocket.compression()*
  - `'cipher'`: a three-value tuple containing the name of the cipher being used, the version of the SSL protocol that defines its use, and the number of secret bits being used; result of *ssl.SSLSocket.cipher()*
  - `'peercert'`: peer certificate; result of *ssl.SSLSocket.getpeercert()*
  - `'sslcontext'`: *ssl.SSLContext* instance
  - `'ssl_object'`: *ssl.SSLObject* or *ssl.SSLSocket* instance
- pipe:
  - `'pipe'`: pipe object

- subprocess:
  - `'subprocess'`: *subprocess.Popen* instance

`set_protocol`(*protocol*)
Set a new protocol. Switching protocol should only be done when both protocols are documented to support the switch.

New in version 3.5.3.

`get_protocol`()
Return the current protocol.

New in version 3.5.3.

Changed in version 3.5.1: `'ssl_object'` info was added to SSL sockets.

ReadTransport

`class asyncio.ReadTransport`
Interface for read-only transports.

`is_reading`()
Return `True` if the transport is receiving new data.

New in version 3.7.

`pause_reading`()
Pause the receiving end of the transport. No data will be passed to the protocol's `data_received()` method until *resume_reading()* is called.

Changed in version 3.7: The method is idempotent, i.e. it can be called when the transport is already paused or closed.

`resume_reading`()
Resume the receiving end. The protocol's `data_received()` method will be called once again if some data is available for reading.

Changed in version 3.7: The method is idempotent, i.e. it can be called when the transport is already reading.

WriteTransport

`class asyncio.WriteTransport`
Interface for write-only transports.

`abort`()
Close the transport immediately, without waiting for pending operations to complete. Buffered data will be lost. No more data will be received. The protocol's `connection_lost()` method will eventually be called with *None* as its argument.

`can_write_eof`()
Return *True* if the transport supports *write_eof()*, *False* if not.

`get_write_buffer_size`()
Return the current size of the output buffer used by the transport.

`get_write_buffer_limits`()
Get the *high*- and *low*-water limits for write flow control. Return a tuple `(low, high)` where *low* and *high* are positive number of bytes.

Use *set_write_buffer_limits()* to set the limits.

New in version 3.4.2.

set_write_buffer_limits(*high=None*, *low=None*)
Set the *high*- and *low*-water limits for write flow control.

These two values (measured in number of bytes) control when the protocol's `pause_writing()` and `resume_writing()` methods are called. If specified, the low-water limit must be less than or equal to the high-water limit. Neither *high* nor *low* can be negative.

`pause_writing()` is called when the buffer size becomes greater than or equal to the *high* value. If writing has been paused, `resume_writing()` is called when the buffer size becomes less than or equal to the *low* value.

The defaults are implementation-specific. If only the high-water limit is given, the low-water limit defaults to an implementation-specific value less than or equal to the high-water limit. Setting *high* to zero forces *low* to zero as well, and causes `pause_writing()` to be called whenever the buffer becomes non-empty. Setting *low* to zero causes `resume_writing()` to be called only once the buffer is empty. Use of zero for either limit is generally sub-optimal as it reduces opportunities for doing I/O and computation concurrently.

Use *get_write_buffer_limits()* to get the limits.

write(*data*)
Write some *data* bytes to the transport.

This method does not block; it buffers the data and arranges for it to be sent out asynchronously.

writelines(*list_of_data*)
Write a list (or any iterable) of data bytes to the transport. This is functionally equivalent to calling *write()* on each element yielded by the iterable, but may be implemented more efficiently.

write_eof()
Close the write end of the transport after flushing buffered data. Data may still be received.

This method can raise *NotImplementedError* if the transport (e.g. SSL) doesn't support half-closes.

DatagramTransport

DatagramTransport.**sendto**(*data*, *addr=None*)
Send the *data* bytes to the remote peer given by *addr* (a transport-dependent target address). If *addr* is *None*, the data is sent to the target address given on transport creation.

This method does not block; it buffers the data and arranges for it to be sent out asynchronously.

DatagramTransport.**abort**()
Close the transport immediately, without waiting for pending operations to complete. Buffered data will be lost. No more data will be received. The protocol's `connection_lost()` method will eventually be called with *None* as its argument.

BaseSubprocessTransport

class asyncio.**BaseSubprocessTransport**

get_pid()
Return the subprocess process id as an integer.

get_pipe_transport(*fd*)
Return the transport for the communication pipe corresponding to the integer file descriptor *fd*:

- 0: readable streaming transport of the standard input (*stdin*), or *None* if the subprocess was not created with `stdin=PIPE`
- 1: writable streaming transport of the standard output (*stdout*), or *None* if the subprocess was not created with `stdout=PIPE`
- 2: writable streaming transport of the standard error (*stderr*), or *None* if the subprocess was not created with `stderr=PIPE`
- other *fd*: *None*

`get_returncode()`
Return the subprocess returncode as an integer or *None* if it hasn't returned, similarly to the *subprocess.Popen.returncode* attribute.

`kill()`
Kill the subprocess, as in *subprocess.Popen.kill()*.

On POSIX systems, the function sends SIGKILL to the subprocess. On Windows, this method is an alias for *terminate()*.

`send_signal(`*signal*`)`
Send the *signal* number to the subprocess, as in *subprocess.Popen.send_signal()*.

`terminate()`
Ask the subprocess to stop, as in *subprocess.Popen.terminate()*. This method is an alias for the *close()* method.

On POSIX systems, this method sends SIGTERM to the subprocess. On Windows, the Windows API function TerminateProcess() is called to stop the subprocess.

`close()`
Ask the subprocess to stop by calling the *terminate()* method if the subprocess hasn't returned yet, and close transports of all pipes (*stdin*, *stdout* and *stderr*).

Protocols

asyncio provides base classes that you can subclass to implement your network protocols. Those classes are used in conjunction with *transports* (see below): the protocol parses incoming data and asks for the writing of outgoing data, while the transport is responsible for the actual I/O and buffering.

When subclassing a protocol class, it is recommended you override certain methods. Those methods are callbacks: they will be called by the transport on certain events (for example when some data is received); you shouldn't call them yourself, unless you are implementing a transport.

Note: All callbacks have default implementations, which are empty. Therefore, you only need to implement the callbacks for the events in which you are interested.

Protocol classes

`class asyncio.Protocol`
The base class for implementing streaming protocols (for use with e.g. TCP and SSL transports).

`class asyncio.BufferedProtocol`
A base class for implementing streaming protocols with manual control of the receive buffer.

New in version 3.7: **Important:** this has been added to asyncio in Python 3.7 *on a provisional basis*! Treat it as an experimental API that might be changed or removed in Python 3.8.

class asyncio.DatagramProtocol
The base class for implementing datagram protocols (for use with e.g. UDP transports).

class asyncio.SubprocessProtocol
The base class for implementing protocols communicating with child processes (through a set of unidirectional pipes).

Connection callbacks

These callbacks may be called on *Protocol*, *DatagramProtocol* and *SubprocessProtocol* instances:

BaseProtocol.connection_made(*transport*)
Called when a connection is made.

The *transport* argument is the transport representing the connection. You are responsible for storing it somewhere (e.g. as an attribute) if you need to.

BaseProtocol.connection_lost(*exc*)
Called when the connection is lost or closed.

The argument is either an exception object or *None*. The latter means a regular EOF is received, or the connection was aborted or closed by this side of the connection.

connection_made() and *connection_lost()* are called exactly once per successful connection. All other callbacks will be called between those two methods, which allows for easier resource management in your protocol implementation.

The following callbacks may be called only on *SubprocessProtocol* instances:

SubprocessProtocol.pipe_data_received(*fd*, *data*)
Called when the child process writes data into its stdout or stderr pipe. *fd* is the integer file descriptor of the pipe. *data* is a non-empty bytes object containing the data.

SubprocessProtocol.pipe_connection_lost(*fd*, *exc*)
Called when one of the pipes communicating with the child process is closed. *fd* is the integer file descriptor that was closed.

SubprocessProtocol.process_exited()
Called when the child process has exited.

Streaming protocols

The following callbacks are called on *Protocol* instances:

Protocol.data_received(*data*)
Called when some data is received. *data* is a non-empty bytes object containing the incoming data.

Note: Whether the data is buffered, chunked or reassembled depends on the transport. In general, you shouldn't rely on specific semantics and instead make your parsing generic and flexible enough. However, data is always received in the correct order.

Protocol.eof_received()
Called when the other end signals it won't send any more data (for example by calling `write_eof()`, if the other end also uses asyncio).

This method may return a false value (including `None`), in which case the transport will close itself. Conversely, if this method returns a true value, closing the transport is up to the protocol. Since the default implementation returns `None`, it implicitly closes the connection.

Note: Some transports such as SSL don't support half-closed connections, in which case returning true from this method will not prevent closing the connection.

`data_received()` can be called an arbitrary number of times during a connection. However, `eof_received()` is called at most once and, if called, `data_received()` won't be called after it.

State machine:

```
start -> connection_made
    [-> data_received]*
    [-> eof_received]?
-> connection_lost -> end
```

Streaming protocols with manual receive buffer control

New in version 3.7: **Important:** *BufferedProtocol* has been added to asyncio in Python 3.7 *on a provisional basis*! Consider it as an experimental API that might be changed or removed in Python 3.8.

Event methods, such as *AbstractEventLoop.create_server()* and *AbstractEventLoop.create_connection()*, accept factories that return protocols that implement this interface.

The idea of BufferedProtocol is that it allows to manually allocate and control the receive buffer. Event loops can then use the buffer provided by the protocol to avoid unnecessary data copies. This can result in noticeable performance improvement for protocols that receive big amounts of data. Sophisticated protocols implementations can allocate the buffer only once at creation time.

The following callbacks are called on *BufferedProtocol* instances:

`BufferedProtocol.get_buffer(`*sizehint*`)`
Called to allocate a new receive buffer.

sizehint is a recommended minimal size for the returned buffer. It is acceptable to return smaller or bigger buffers than what *sizehint* suggests. When set to -1, the buffer size can be arbitrary. It is an error to return a zero-sized buffer.

Must return an object that implements the buffer protocol.

`BufferedProtocol.buffer_updated(`*nbytes*`)`
Called when the buffer was updated with the received data.

nbytes is the total number of bytes that were written to the buffer.

`BufferedProtocol.eof_received()`
See the documentation of the *Protocol.eof_received()* method.

`get_buffer()` can be called an arbitrary number of times during a connection. However, `eof_received()` is called at most once and, if called, `get_buffer()` and `buffer_updated()` won't be called after it.

State machine:

```
start -> connection_made
    [-> get_buffer
        [-> buffer_updated]?
    ]*
    [-> eof_received]?
-> connection_lost -> end
```

Datagram protocols

The following callbacks are called on *DatagramProtocol* instances.

DatagramProtocol.**datagram_received**(*data*, *addr*)
Called when a datagram is received. *data* is a bytes object containing the incoming data. *addr* is the address of the peer sending the data; the exact format depends on the transport.

DatagramProtocol.**error_received**(*exc*)
Called when a previous send or receive operation raises an *OSError*. *exc* is the *OSError* instance.

This method is called in rare conditions, when the transport (e.g. UDP) detects that a datagram couldn't be delivered to its recipient. In many conditions though, undeliverable datagrams will be silently dropped.

Flow control callbacks

These callbacks may be called on *Protocol*, *DatagramProtocol* and *SubprocessProtocol* instances:

BaseProtocol.**pause_writing**()
Called when the transport's buffer goes over the high-water mark.

BaseProtocol.**resume_writing**()
Called when the transport's buffer drains below the low-water mark.

`pause_writing()` and `resume_writing()` calls are paired – `pause_writing()` is called once when the buffer goes strictly over the high-water mark (even if subsequent writes increases the buffer size even more), and eventually `resume_writing()` is called once when the buffer size reaches the low-water mark.

Note: If the buffer size equals the high-water mark, `pause_writing()` is not called – it must go strictly over. Conversely, `resume_writing()` is called when the buffer size is equal or lower than the low-water mark. These end conditions are important to ensure that things go as expected when either mark is zero.

Note: On BSD systems (OS X, FreeBSD, etc.) flow control is not supported for *DatagramProtocol*, because send failures caused by writing too many packets cannot be detected easily. The socket always appears 'ready' and excess packets are dropped; an *OSError* with errno set to *errno.ENOBUFS* may or may not be raised; if it is raised, it will be reported to *DatagramProtocol.error_received()* but otherwise ignored.

Coroutines and protocols

Coroutines can be scheduled in a protocol method using *ensure_future()*, but there is no guarantee made about the execution order. Protocols are not aware of coroutines created in protocol methods and so will not wait for them.

To have a reliable execution order, use *stream objects* in a coroutine with `await`. For example, the *StreamWriter.drain()* coroutine can be used to wait until the write buffer is flushed.

Protocol examples

TCP echo client protocol

TCP echo client using the *AbstractEventLoop.create_connection()* method, send data and wait until the connection is closed:

```
import asyncio

class EchoClientProtocol(asyncio.Protocol):
    def __init__(self, message, loop):
        self.message = message
        self.loop = loop

    def connection_made(self, transport):
        transport.write(self.message.encode())
        print('Data sent: {!r}'.format(self.message))

    def data_received(self, data):
        print('Data received: {!r}'.format(data.decode()))

    def connection_lost(self, exc):
        print('The server closed the connection')
        print('Stop the event loop')
        self.loop.stop()

loop = asyncio.get_event_loop()
message = 'Hello World!'
coro = loop.create_connection(lambda: EchoClientProtocol(message, loop),
                              '127.0.0.1', 8888)
loop.run_until_complete(coro)
loop.run_forever()
loop.close()
```

The event loop is running twice. The *run_until_complete()* method is preferred in this short example to raise an exception if the server is not listening, instead of having to write a short coroutine to handle the exception and stop the running loop. At *run_until_complete()* exit, the loop is no longer running, so there is no need to stop the loop in case of an error.

See also:

The *TCP echo client using streams* example uses the *asyncio.open_connection()* function.

TCP echo server protocol

TCP echo server using the *AbstractEventLoop.create_server()* method, send back received data and close the connection:

```
import asyncio

class EchoServerClientProtocol(asyncio.Protocol):
    def connection_made(self, transport):
        peername = transport.get_extra_info('peername')
        print('Connection from {}'.format(peername))
        self.transport = transport

    def data_received(self, data):
```

(continues on next page)

(continued from previous page)

```
        message = data.decode()
        print('Data received: {!r}'.format(message))

        print('Send: {!r}'.format(message))
        self.transport.write(data)

        print('Close the client socket')
        self.transport.close()

loop = asyncio.get_event_loop()
# Each client connection will create a new protocol instance
coro = loop.create_server(EchoServerClientProtocol, '127.0.0.1', 8888)
server = loop.run_until_complete(coro)

# Serve requests until Ctrl+C is pressed
print('Serving on {}'.format(server.sockets[0].getsockname()))
try:
    loop.run_forever()
except KeyboardInterrupt:
    pass

# Close the server
server.close()
loop.run_until_complete(server.wait_closed())
loop.close()
```

`Transport.close()` can be called immediately after *`WriteTransport.write()`* even if data are not sent yet on the socket: both methods are asynchronous. `await` is not needed because these transport methods are not coroutines.

See also:

The *TCP echo server using streams* example uses the *`asyncio.start_server()`* function.

UDP echo client protocol

UDP echo client using the *`AbstractEventLoop.create_datagram_endpoint()`* method, send data and close the transport when we received the answer:

```
import asyncio

class EchoClientProtocol:
    def __init__(self, message, loop):
        self.message = message
        self.loop = loop
        self.transport = None

    def connection_made(self, transport):
        self.transport = transport
        print('Send:', self.message)
        self.transport.sendto(self.message.encode())

    def datagram_received(self, data, addr):
        print("Received:", data.decode())

        print("Close the socket")
```

(continues on next page)

(continued from previous page)

```
        self.transport.close()

    def error_received(self, exc):
        print('Error received:', exc)

    def connection_lost(self, exc):
        print("Socket closed, stop the event loop")
        loop = asyncio.get_event_loop()
        loop.stop()

loop = asyncio.get_event_loop()
message = "Hello World!"
connect = loop.create_datagram_endpoint(
    lambda: EchoClientProtocol(message, loop),
    remote_addr=('127.0.0.1', 9999))
transport, protocol = loop.run_until_complete(connect)
loop.run_forever()
transport.close()
loop.close()
```

UDP echo server protocol

UDP echo server using the *AbstractEventLoop.create_datagram_endpoint()* method, send back received data:

```
import asyncio

class EchoServerProtocol:
    def connection_made(self, transport):
        self.transport = transport

    def datagram_received(self, data, addr):
        message = data.decode()
        print('Received %r from %s' % (message, addr))
        print('Send %r to %s' % (message, addr))
        self.transport.sendto(data, addr)

loop = asyncio.get_event_loop()
print("Starting UDP server")
# One protocol instance will be created to serve all client requests
listen = loop.create_datagram_endpoint(
    EchoServerProtocol, local_addr=('127.0.0.1', 9999))
transport, protocol = loop.run_until_complete(listen)

try:
    loop.run_forever()
except KeyboardInterrupt:
    pass

transport.close()
loop.close()
```

Register an open socket to wait for data using a protocol

Wait until a socket receives data using the *AbstractEventLoop.create_connection()* method with a protocol, and then close the event loop

```
import asyncio
from socket import socketpair

# Create a pair of connected sockets
rsock, wsock = socketpair()
loop = asyncio.get_event_loop()

class MyProtocol(asyncio.Protocol):
    transport = None

    def connection_made(self, transport):
        self.transport = transport

    def data_received(self, data):
        print("Received:", data.decode())

        # We are done: close the transport (it will call connection_lost())
        self.transport.close()

    def connection_lost(self, exc):
        # The socket has been closed, stop the event loop
        loop.stop()

# Register the socket to wait for data
connect_coro = loop.create_connection(MyProtocol, sock=rsock)
transport, protocol = loop.run_until_complete(connect_coro)

# Simulate the reception of data from the network
loop.call_soon(wsock.send, 'abc'.encode())

# Run the event loop
loop.run_forever()

# We are done, close sockets and the event loop
rsock.close()
wsock.close()
loop.close()
```

See also:

The *watch a file descriptor for read events* example uses the low-level *AbstractEventLoop.add_reader()* method to register the file descriptor of a socket.

The *register an open socket to wait for data using streams* example uses high-level streams created by the *open_connection()* function in a coroutine.

19.5.5 Streams (coroutine based API)

Source code: Lib/asyncio/streams.py

Stream functions

Note: The top-level functions in this module are meant as convenience wrappers only; there's really nothing special there, and if they don't do exactly what you want, feel free to copy their code.

coroutine asyncio.open_connection(*host=None*, *port=None*, ***, *loop=None*, *limit=None*, *ssl=None*, *family=0*, *proto=0*, *flags=0*, *sock=None*, *local_addr=None*, *server_hostname=None*, *ssl_handshake_timeout=None*)

A wrapper for *create_connection()* returning a (reader, writer) pair.

The reader returned is a *StreamReader* instance; the writer is a *StreamWriter* instance.

When specified, the *loop* argument determines which event loop to use, and the *limit* argument determines the buffer size limit used by the returned *StreamReader* instance.

The rest of the arguments are passed directly to *AbstractEventLoop.create_connection()*.

This function is a *coroutine*.

New in version 3.7: The *ssl_handshake_timeout* parameter.

coroutine asyncio.start_server(*client_connected_cb*, *host=None*, *port=None*, ***, *loop=None*, *limit=None*, *family=socket.AF_UNSPEC*, *flags=socket.AI_PASSIVE*, *sock=None*, *backlog=100*, *ssl=None*, *reuse_address=None*, *reuse_port=None*, *ssl_handshake_timeout=None*, *start_serving=True*)

Start a socket server, with a callback for each client connected. The return value is the same as *create_server()*.

The *client_connected_cb* callback is called whenever a new client connection is established. It receives a reader/writer pair as two arguments, the first is a *StreamReader* instance, and the second is a *StreamWriter* instance.

client_connected_cb accepts a plain callable or a *coroutine function*; if it is a coroutine function, it will be automatically converted into a *Task*.

When specified, the *loop* argument determines which event loop to use, and the *limit* argument determines the buffer size limit used by the *StreamReader* instance passed to *client_connected_cb*.

The rest of the arguments are passed directly to *create_server()*.

This function is a *coroutine*.

New in version 3.7: The *ssl_handshake_timeout* and *start_serving* parameters.

coroutine asyncio.open_unix_connection(*path=None*, ***, *loop=None*, *limit=None*, *ssl=None*, *sock=None*, *server_hostname=None*, *ssl_handshake_timeout=None*)

A wrapper for *create_unix_connection()* returning a (reader, writer) pair.

When specified, the *loop* argument determines which event loop to use, and the *limit* argument determines the buffer size limit used by the returned *StreamReader* instance.

The rest of the arguments are passed directly to *create_unix_connection()*.

This function is a *coroutine*.

Availability: UNIX.

New in version 3.7: The *ssl_handshake_timeout* parameter.

Changed in version 3.7: The *path* parameter can now be a *path-like object*

coroutine asyncio.start_unix_server(*client_connected_cb*, *path=None*, ***, *loop=None*, *limit=None*, *sock=None*, *backlog=100*, *ssl=None*, *ssl_handshake_timeout=None*, *start_serving=True*)

Start a UNIX Domain Socket server, with a callback for each client connected.

The *client_connected_cb* callback is called whenever a new client connection is established. It receives a reader/writer pair as two arguments, the first is a *StreamReader* instance, and the second is a *StreamWriter* instance.

client_connected_cb accepts a plain callable or a *coroutine function*; if it is a coroutine function, it will be automatically converted into a *Task*.

When specified, the *loop* argument determines which event loop to use, and the *limit* argument determines the buffer size limit used by the *StreamReader* instance passed to *client_connected_cb*.

The rest of the arguments are passed directly to *create_unix_server()*.

This function is a *coroutine*.

Availability: UNIX.

New in version 3.7: The *ssl_handshake_timeout* and *start_serving* parameters.

Changed in version 3.7: The *path* parameter can now be a *path-like object*.

StreamReader

class asyncio.StreamReader(*limit=None*, *loop=None*)

This class is *not thread safe*.

exception()
Get the exception.

feed_eof()
Acknowledge the EOF.

feed_data(*data*)
Feed *data* bytes in the internal buffer. Any operations waiting for the data will be resumed.

set_exception(*exc*)
Set the exception.

set_transport(*transport*)
Set the transport.

coroutine read(*n=-1*)
Read up to *n* bytes. If *n* is not provided, or set to `-1`, read until EOF and return all read bytes.

If the EOF was received and the internal buffer is empty, return an empty `bytes` object.

This method is a *coroutine*.

coroutine readline()
Read one line, where "line" is a sequence of bytes ending with `\n`.

If EOF is received, and `\n` was not found, the method will return the partial read bytes.

If the EOF was received and the internal buffer is empty, return an empty `bytes` object.

This method is a *coroutine*.

coroutine readexactly(*n*)
Read exactly *n* bytes. Raise an *IncompleteReadError* if the end of the stream is reached before *n* can be read, the *IncompleteReadError.partial* attribute of the exception contains the partial read bytes.

This method is a *coroutine*.

coroutine readuntil(*separator=b'\n'*)
Read data from the stream until `separator` is found.

On success, the data and separator will be removed from the internal buffer (consumed). Returned data will include the separator at the end.

Configured stream limit is used to check result. Limit sets the maximal length of data that can be returned, not counting the separator.

If an EOF occurs and the complete separator is still not found, an *IncompleteReadError* exception will be raised, and the internal buffer will be reset. The *IncompleteReadError.partial* attribute may contain the separator partially.

If the data cannot be read because of over limit, a *LimitOverrunError* exception will be raised, and the data will be left in the internal buffer, so it can be read again.

New in version 3.5.2.

at_eof()
Return `True` if the buffer is empty and *feed_eof()* was called.

StreamWriter

class asyncio.StreamWriter(*transport*, *protocol*, *reader*, *loop*)
Wraps a Transport.

This exposes *write()*, *writelines()*, *can_write_eof()*, *write_eof()*, *get_extra_info()* and *close()*. It adds *drain()* which returns an optional *Future* on which you can wait for flow control. It also adds a transport attribute which references the `Transport` directly.

This class is *not thread safe*.

transport
Transport.

can_write_eof()
Return *True* if the transport supports *write_eof()*, *False* if not. See *WriteTransport.can_write_eof()*.

close()
Close the transport: see *BaseTransport.close()*.

is_closing()
Return `True` if the writer is closing or is closed.

New in version 3.7.

coroutine wait_closed()
Wait until the writer is closed.

Should be called after *close()* to wait until the underlying connection (and the associated transport/protocol pair) is closed.

New in version 3.7.

coroutine drain()
Let the write buffer of the underlying transport a chance to be flushed.

The intended use is to write:

```
w.write(data)
await w.drain()
```

When the size of the transport buffer reaches the high-water limit (the protocol is paused), block until the size of the buffer is drained down to the low-water limit and the protocol is resumed. When there is nothing to wait for, the yield-from continues immediately.

Yielding from *drain()* gives the opportunity for the loop to schedule the write operation and flush the buffer. It should especially be used when a possibly large amount of data is written to the transport, and the coroutine does not yield-from between calls to *write()*.

This method is a *coroutine*.

get_extra_info(*name*, *default=None*)
Return optional transport information: see *BaseTransport.get_extra_info()*.

write(*data*)
Write some *data* bytes to the transport: see *WriteTransport.write()*.

writelines(*data*)
Write a list (or any iterable) of data bytes to the transport: see *WriteTransport.writelines()*.

write_eof()
Close the write end of the transport after flushing buffered data: see *WriteTransport.write_eof()*.

StreamReaderProtocol

class asyncio.StreamReaderProtocol(*stream_reader*, *client_connected_cb=None*, *loop=None*)
Trivial helper class to adapt between *Protocol* and *StreamReader*. Subclass of *Protocol*.

stream_reader is a *StreamReader* instance, *client_connected_cb* is an optional function called with (stream_reader, stream_writer) when a connection is made, *loop* is the event loop instance to use.

(This is a helper class instead of making *StreamReader* itself a *Protocol* subclass, because the *StreamReader* has other potential uses, and to prevent the user of the *StreamReader* from accidentally calling inappropriate methods of the protocol.)

IncompleteReadError

exception asyncio.IncompleteReadError

Incomplete read error, subclass of *EOFError*.

expected
Total number of expected bytes (*int*).

partial
Read bytes string before the end of stream was reached (*bytes*).

LimitOverrunError

exception asyncio.LimitOverrunError
Reached the buffer limit while looking for a separator.

consumed
Total number of to be consumed bytes.

Stream examples

TCP echo client using streams

TCP echo client using the *asyncio.open_connection()* function:

```
import asyncio

async def tcp_echo_client(message, loop):
    reader, writer = await asyncio.open_connection('127.0.0.1', 8888,
                                                   loop=loop)

    print('Send: %r' % message)
    writer.write(message.encode())

    data = await reader.read(100)
    print('Received: %r' % data.decode())

    print('Close the socket')
    writer.close()

message = 'Hello World!'
loop = asyncio.get_event_loop()
loop.run_until_complete(tcp_echo_client(message, loop))
loop.close()
```

See also:

The *TCP echo client protocol* example uses the *AbstractEventLoop.create_connection()* method.

TCP echo server using streams

TCP echo server using the *asyncio.start_server()* function:

```
import asyncio

async def handle_echo(reader, writer):
    data = await reader.read(100)
    message = data.decode()
    addr = writer.get_extra_info('peername')
    print("Received %r from %r" % (message, addr))

    print("Send: %r" % message)
    writer.write(data)
    await writer.drain()

    print("Close the client socket")
    writer.close()

loop = asyncio.get_event_loop()
coro = asyncio.start_server(handle_echo, '127.0.0.1', 8888, loop=loop)
server = loop.run_until_complete(coro)

# Serve requests until Ctrl+C is pressed
print('Serving on {}'.format(server.sockets[0].getsockname()))
try:
    loop.run_forever()
```

(continues on next page)

(continued from previous page)

```
except KeyboardInterrupt:
    pass

# Close the server
server.close()
loop.run_until_complete(server.wait_closed())
loop.close()
```

See also:

The *TCP echo server protocol* example uses the *AbstractEventLoop.create_server()* method.

Get HTTP headers

Simple example querying HTTP headers of the URL passed on the command line:

```
import asyncio
import urllib.parse
import sys

@asyncio.coroutine
def print_http_headers(url):
    url = urllib.parse.urlsplit(url)
    if url.scheme == 'https':
        connect = asyncio.open_connection(url.hostname, 443, ssl=True)
    else:
        connect = asyncio.open_connection(url.hostname, 80)
    reader, writer = await connect
    query = ('HEAD {path} HTTP/1.0\r\n'
             'Host: {hostname}\r\n'
             '\r\n').format(path=url.path or '/', hostname=url.hostname)
    writer.write(query.encode('latin-1'))
    while True:
        line = await reader.readline()
        if not line:
            break
        line = line.decode('latin1').rstrip()
        if line:
            print('HTTP header> %s' % line)

    # Ignore the body, close the socket
    writer.close()

url = sys.argv[1]
loop = asyncio.get_event_loop()
task = asyncio.ensure_future(print_http_headers(url))
loop.run_until_complete(task)
loop.close()
```

Usage:

```
python example.py http://example.com/path/page.html
```

or with HTTPS:

```
python example.py https://example.com/path/page.html
```

Register an open socket to wait for data using streams

Coroutine waiting until a socket receives data using the *open_connection()* function:

```
import asyncio
from socket import socketpair

async def wait_for_data(loop):
    # Create a pair of connected sockets
    rsock, wsock = socketpair()

    # Register the open socket to wait for data
    reader, writer = await asyncio.open_connection(sock=rsock, loop=loop)

    # Simulate the reception of data from the network
    loop.call_soon(wsock.send, 'abc'.encode())

    # Wait for data
    data = await reader.read(100)

    # Got data, we are done: close the socket
    print("Received:", data.decode())
    writer.close()

    # Close the second socket
    wsock.close()

loop = asyncio.get_event_loop()
loop.run_until_complete(wait_for_data(loop))
loop.close()
```

See also:

The *register an open socket to wait for data using a protocol* example uses a low-level protocol created by the *AbstractEventLoop.create_connection()* method.

The *watch a file descriptor for read events* example uses the low-level *AbstractEventLoop.add_reader()* method to register the file descriptor of a socket.

19.5.6 Subprocess

Source code: Lib/asyncio/subprocess.py

Windows event loop

On Windows, the default event loop is *SelectorEventLoop* which does not support subprocesses. *ProactorEventLoop* should be used instead. Example to use it on Windows:

```
import asyncio, sys

if sys.platform == 'win32':
    loop = asyncio.ProactorEventLoop()
    asyncio.set_event_loop(loop)
```

See also:

Available event loops and *Platform support*.

Create a subprocess: high-level API using Process

coroutine asyncio.create_subprocess_exec(**args*, *stdin=None*, *stdout=None*, *stderr=None*, *loop=None*, *limit=None*, ***kwds*)

Create a subprocess.

The *limit* parameter sets the buffer limit passed to the *StreamReader*. See *AbstractEventLoop.subprocess_exec()* for other parameters.

Return a *Process* instance.

This function is a *coroutine*.

coroutine asyncio.create_subprocess_shell(*cmd*, *stdin=None*, *stdout=None*, *stderr=None*, *loop=None*, *limit=None*, ***kwds*)

Run the shell command *cmd*.

The *limit* parameter sets the buffer limit passed to the *StreamReader*. See *AbstractEventLoop.subprocess_shell()* for other parameters.

Return a *Process* instance.

It is the application's responsibility to ensure that all whitespace and metacharacters are quoted appropriately to avoid shell injection vulnerabilities. The *shlex.quote()* function can be used to properly escape whitespace and shell metacharacters in strings that are going to be used to construct shell commands.

This function is a *coroutine*.

Use the *AbstractEventLoop.connect_read_pipe()* and *AbstractEventLoop.connect_write_pipe()* methods to connect pipes.

Create a subprocess: low-level API using subprocess.Popen

Run subprocesses asynchronously using the *subprocess* module.

coroutine AbstractEventLoop.subprocess_exec(*protocol_factory*, **args*, *stdin=subprocess.PIPE*, *stdout=subprocess.PIPE*, *stderr=subprocess.PIPE*, ***kwargs*)

Create a subprocess from one or more string arguments (character strings or bytes strings encoded to the *filesystem encoding*), where the first string specifies the program to execute, and the remaining strings specify the program's arguments. (Thus, together the string arguments form the `sys.argv` value of the program, assuming it is a Python script.) This is similar to the standard library *subprocess.Popen* class called with shell=False and the list of strings passed as the first argument; however, where *Popen* takes a single argument which is list of strings, *subprocess_exec()* takes multiple string arguments.

The *protocol_factory* must instantiate a subclass of the *asyncio.SubprocessProtocol* class.

Other parameters:

- *stdin*: Either a file-like object representing the pipe to be connected to the subprocess's standard input stream using *connect_write_pipe()*, or the constant *subprocess.PIPE* (the default). By default a new pipe will be created and connected.
- *stdout*: Either a file-like object representing the pipe to be connected to the subprocess's standard output stream using *connect_read_pipe()*, or the constant *subprocess.PIPE* (the default). By default a new pipe will be created and connected.
- *stderr*: Either a file-like object representing the pipe to be connected to the subprocess's standard error stream using *connect_read_pipe()*, or one of the constants *subprocess.PIPE* (the default) or *subprocess.STDOUT*. By default a new pipe will be created and connected. When *subprocess.STDOUT* is specified, the subprocess's standard error stream will be connected to the same pipe as the standard output stream.

- All other keyword arguments are passed to *subprocess.Popen* without interpretation, except for *bufsize*, *universal_newlines* and *shell*, which should not be specified at all.

Returns a pair of `(transport, protocol)`, where *transport* is an instance of *BaseSubprocessTransport*.

This method is a *coroutine*.

See the constructor of the *subprocess.Popen* class for parameters.

coroutine AbstractEventLoop.**subprocess_shell**(*protocol_factory*, *cmd*, ***, *stdin=subprocess.PIPE*, *stdout=subprocess.PIPE*, *stderr=subprocess.PIPE*, ***kwargs*)

Create a subprocess from *cmd*, which is a character string or a bytes string encoded to the *filesystem encoding*, using the platform's "shell" syntax. This is similar to the standard library *subprocess.Popen* class called with `shell=True`.

The *protocol_factory* must instantiate a subclass of the *asyncio.SubprocessProtocol* class.

See *subprocess_exec()* for more details about the remaining arguments.

Returns a pair of `(transport, protocol)`, where *transport* is an instance of *BaseSubprocessTransport*.

It is the application's responsibility to ensure that all whitespace and metacharacters are quoted appropriately to avoid shell injection vulnerabilities. The *shlex.quote()* function can be used to properly escape whitespace and shell metacharacters in strings that are going to be used to construct shell commands.

This method is a *coroutine*.

See also:

The *AbstractEventLoop.connect_read_pipe()* and *AbstractEventLoop.connect_write_pipe()* methods.

Constants

asyncio.subprocess.**PIPE**
Special value that can be used as the *stdin*, *stdout* or *stderr* argument to *create_subprocess_shell()* and *create_subprocess_exec()* and indicates that a pipe to the standard stream should be opened.

asyncio.subprocess.**STDOUT**
Special value that can be used as the *stderr* argument to *create_subprocess_shell()* and *create_subprocess_exec()* and indicates that standard error should go into the same handle as standard output.

asyncio.subprocess.**DEVNULL**
Special value that can be used as the *stdin*, *stdout* or *stderr* argument to *create_subprocess_shell()* and *create_subprocess_exec()* and indicates that the special file *os.devnull* will be used.

Process

class asyncio.subprocess.**Process**
A subprocess created by the *create_subprocess_exec()* or the *create_subprocess_shell()* function.

The API of the *Process* class was designed to be close to the API of the *subprocess.Popen* class, but there are some differences:

- There is no explicit *poll()* method

- The *communicate()* and *wait()* methods don't take a *timeout* parameter: use the *wait_for()* function
- The *universal_newlines* parameter is not supported (only bytes strings are supported)
- The *wait()* method of the *Process* class is asynchronous whereas the *wait()* method of the *Popen* class is implemented as a busy loop.

This class is *not thread safe*. See also the *Subprocess and threads* section.

coroutine wait()
Wait for child process to terminate. Set and return *returncode* attribute.

This method is a *coroutine*.

Note: This will deadlock when using `stdout=PIPE` or `stderr=PIPE` and the child process generates enough output to a pipe such that it blocks waiting for the OS pipe buffer to accept more data. Use the *communicate()* method when using pipes to avoid that.

---

coroutine communicate(*input=None*)
Interact with process: Send data to stdin. Read data from stdout and stderr, until end-of-file is reached. Wait for process to terminate. The optional *input* argument should be data to be sent to the child process, or `None`, if no data should be sent to the child. The type of *input* must be bytes.

communicate() returns a tuple `(stdout_data, stderr_data)`.

If a *BrokenPipeError* or *ConnectionResetError* exception is raised when writing *input* into stdin, the exception is ignored. It occurs when the process exits before all data are written into stdin.

Note that if you want to send data to the process's stdin, you need to create the Process object with `stdin=PIPE`. Similarly, to get anything other than `None` in the result tuple, you need to give `stdout=PIPE` and/or `stderr=PIPE` too.

This method is a *coroutine*.

Note: The data read is buffered in memory, so do not use this method if the data size is large or unlimited.

Changed in version 3.4.2: The method now ignores *BrokenPipeError* and *ConnectionResetError*.

send_signal(*signal*)
Sends the signal *signal* to the child process.

Note: On Windows, `SIGTERM` is an alias for *terminate()*. `CTRL_C_EVENT` and `CTRL_BREAK_EVENT` can be sent to processes started with a *creationflags* parameter which includes `CREATE_NEW_PROCESS_GROUP`.

---

terminate()
Stop the child. On Posix OSs the method sends `signal.SIGTERM` to the child. On Windows the Win32 API function `TerminateProcess()` is called to stop the child.

kill()
Kills the child. On Posix OSs the function sends `SIGKILL` to the child. On Windows *kill()* is an alias for *terminate()*.

stdin
Standard input stream (*StreamWriter*), `None` if the process was created with `stdin=None`.

stdout
Standard output stream (*StreamReader*), `None` if the process was created with `stdout=None`.

stderr
Standard error stream (*StreamReader*), `None` if the process was created with `stderr=None`.

> **Warning:** Use the *communicate()* method rather than *.stdin.write*, *.stdout.read* or *.stderr.read* to avoid deadlocks due to streams pausing reading or writing and blocking the child process.

pid
The identifier of the process.

Note that for processes created by the *create_subprocess_shell()* function, this attribute is the process identifier of the spawned shell.

returncode
Return code of the process when it exited. A `None` value indicates that the process has not terminated yet.

A negative value `-N` indicates that the child was terminated by signal `N` (Unix only).

Subprocess and threads

asyncio supports running subprocesses from different threads, but there are limits:

- An event loop must run in the main thread
- The child watcher must be instantiated in the main thread, before executing subprocesses from other threads. Call the `get_child_watcher()` function in the main thread to instantiate the child watcher.

The *asyncio.subprocess.Process* class is not thread safe.

See also:

The *Concurrency and multithreading in asyncio* section.

Subprocess examples

Subprocess using transport and protocol

Example of a subprocess protocol using to get the output of a subprocess and to wait for the subprocess exit. The subprocess is created by the *AbstractEventLoop.subprocess_exec()* method:

```
import asyncio
import sys

class DateProtocol(asyncio.SubprocessProtocol):
    def __init__(self, exit_future):
        self.exit_future = exit_future
        self.output = bytearray()

    def pipe_data_received(self, fd, data):
        self.output.extend(data)
```

(continues on next page)

(continued from previous page)

```
    def process_exited(self):
        self.exit_future.set_result(True)

async def get_date(loop):
    code = 'import datetime; print(datetime.datetime.now())'
    exit_future = asyncio.Future(loop=loop)

    # Create the subprocess controlled by the protocol DateProtocol,
    # redirect the standard output into a pipe
    transport, protocol = await loop.subprocess_exec(
        lambda: DateProtocol(exit_future),
        sys.executable, '-c', code,
        stdin=None, stderr=None)

    # Wait for the subprocess exit using the process_exited() method
    # of the protocol
    await exit_future

    # Close the stdout pipe
    transport.close()

    # Read the output which was collected by the pipe_data_received()
    # method of the protocol
    data = bytes(protocol.output)
    return data.decode('ascii').rstrip()

if sys.platform == "win32":
    loop = asyncio.ProactorEventLoop()
    asyncio.set_event_loop(loop)
else:
    loop = asyncio.get_event_loop()

date = loop.run_until_complete(get_date(loop))
print("Current date: %s" % date)
loop.close()
```

Subprocess using streams

Example using the *Process* class to control the subprocess and the *StreamReader* class to read from the standard output. The subprocess is created by the *create_subprocess_exec()* function:

```
import asyncio.subprocess
import sys

@asyncio.coroutine
def get_date():
    code = 'import datetime; print(datetime.datetime.now())'

    # Create the subprocess, redirect the standard output into a pipe
    proc = await asyncio.create_subprocess_exec(
        sys.executable, '-c', code,
        stdout=asyncio.subprocess.PIPE)

    # Read one line of output
```

(continues on next page)

(continued from previous page)

```
    data = await proc.stdout.readline()
    line = data.decode('ascii').rstrip()

    # Wait for the subprocess exit
    await proc.wait()
    return line

if sys.platform == "win32":
    loop = asyncio.ProactorEventLoop()
    asyncio.set_event_loop(loop)
else:
    loop = asyncio.get_event_loop()

date = loop.run_until_complete(get_date())
print("Current date: %s" % date)
loop.close()
```

19.5.7 Synchronization primitives

Source code: Lib/asyncio/locks.py

Locks:

- *Lock*
- *Event*
- *Condition*

Semaphores:

- *Semaphore*
- *BoundedSemaphore*

asyncio lock API was designed to be close to classes of the *threading* module (*Lock*, *Event*, *Condition*, *Semaphore*, *BoundedSemaphore*), but it has no *timeout* parameter. The *asyncio.wait_for()* function can be used to cancel a task after a timeout.

Lock

class asyncio.Lock(*, *loop=None*)

Primitive lock objects.

A primitive lock is a synchronization primitive that is not owned by a particular coroutine when locked. A primitive lock is in one of two states, 'locked' or 'unlocked'.

The lock is created in the unlocked state. It has two basic methods, *acquire()* and *release()*. When the state is unlocked, acquire() changes the state to locked and returns immediately. When the state is locked, acquire() blocks until a call to release() in another coroutine changes it to unlocked, then the acquire() call resets it to locked and returns. The release() method should only be called in the locked state; it changes the state to unlocked and returns immediately. If an attempt is made to release an unlocked lock, a *RuntimeError* will be raised.

When more than one coroutine is blocked in acquire() waiting for the state to turn to unlocked, only one coroutine proceeds when a release() call resets the state to unlocked; first coroutine which is blocked in acquire() is being processed.

acquire() is a coroutine and should be called with `await`.

Locks support the *context management protocol*.

This class is *not thread safe*.

locked()
Return **True** if the lock is acquired.

coroutine acquire()
Acquire a lock.

This method blocks until the lock is unlocked, then sets it to locked and returns **True**.

This method is a *coroutine*.

release()
Release a lock.

When the lock is locked, reset it to unlocked, and return. If any other coroutines are blocked waiting for the lock to become unlocked, allow exactly one of them to proceed.

When invoked on an unlocked lock, a *RuntimeError* is raised.

There is no return value.

Event

class asyncio.Event(**, loop=None*)
An Event implementation, asynchronous equivalent to *threading.Event*.

Class implementing event objects. An event manages a flag that can be set to true with the *set()* method and reset to false with the *clear()* method. The *wait()* method blocks until the flag is true. The flag is initially false.

This class is *not thread safe*.

clear()
Reset the internal flag to false. Subsequently, coroutines calling *wait()* will block until *set()* is called to set the internal flag to true again.

is_set()
Return **True** if and only if the internal flag is true.

set()
Set the internal flag to true. All coroutines waiting for it to become true are awakened. Coroutine that call *wait()* once the flag is true will not block at all.

coroutine wait()
Block until the internal flag is true.

If the internal flag is true on entry, return **True** immediately. Otherwise, block until another coroutine calls *set()* to set the flag to true, then return **True**.

This method is a *coroutine*.

Condition

class asyncio.Condition(*lock=None*, ***, *loop=None*)
A Condition implementation, asynchronous equivalent to *threading.Condition*.

This class implements condition variable objects. A condition variable allows one or more coroutines to wait until they are notified by another coroutine.

If the *lock* argument is given and not **None**, it must be a *Lock* object, and it is used as the underlying lock. Otherwise, a new *Lock* object is created and used as the underlying lock.

Conditions support the *context management protocol*.

This class is *not thread safe*.

coroutine acquire()
Acquire the underlying lock.

This method blocks until the lock is unlocked, then sets it to locked and returns `True`.

This method is a *coroutine*.

notify(*n=1*)
By default, wake up one coroutine waiting on this condition, if any. If the calling coroutine has not acquired the lock when this method is called, a *RuntimeError* is raised.

This method wakes up at most *n* of the coroutines waiting for the condition variable; it is a no-op if no coroutines are waiting.

Note: An awakened coroutine does not actually return from its *wait()* call until it can reacquire the lock. Since *notify()* does not release the lock, its caller should.

---

locked()
Return `True` if the underlying lock is acquired.

notify_all()
Wake up all coroutines waiting on this condition. This method acts like *notify()*, but wakes up all waiting coroutines instead of one. If the calling coroutine has not acquired the lock when this method is called, a *RuntimeError* is raised.

release()
Release the underlying lock.

When the lock is locked, reset it to unlocked, and return. If any other coroutines are blocked waiting for the lock to become unlocked, allow exactly one of them to proceed.

When invoked on an unlocked lock, a *RuntimeError* is raised.

There is no return value.

coroutine wait()
Wait until notified.

If the calling coroutine has not acquired the lock when this method is called, a *RuntimeError* is raised.

This method releases the underlying lock, and then blocks until it is awakened by a *notify()* or *notify_all()* call for the same condition variable in another coroutine. Once awakened, it re-acquires the lock and returns `True`.

This method is a *coroutine*.

coroutine wait_for(*predicate*)
Wait until a predicate becomes true.

The predicate should be a callable which result will be interpreted as a boolean value. The final predicate value is the return value.

This method is a *coroutine*.

Semaphore

class asyncio.Semaphore(*value=1*, ***, *loop=None*)
A Semaphore implementation.

A semaphore manages an internal counter which is decremented by each *acquire()* call and incremented by each *release()* call. The counter can never go below zero; when *acquire()* finds that it is zero, it blocks, waiting until some other coroutine calls *release()*.

The optional argument gives the initial value for the internal counter; it defaults to `1`. If the value given is less than `0`, *ValueError* is raised.

Semaphores support the *context management protocol*.

This class is *not thread safe*.

coroutine acquire()
Acquire a semaphore.

If the internal counter is larger than zero on entry, decrement it by one and return `True` immediately. If it is zero on entry, block, waiting until some other coroutine has called *release()* to make it larger than `0`, and then return `True`.

This method is a *coroutine*.

locked()
Returns `True` if semaphore can not be acquired immediately.

release()
Release a semaphore, incrementing the internal counter by one. When it was zero on entry and another coroutine is waiting for it to become larger than zero again, wake up that coroutine.

BoundedSemaphore

class asyncio.BoundedSemaphore(*value=1*, ***, *loop=None*)
A bounded semaphore implementation. Inherit from *Semaphore*.

This raises *ValueError* in *release()* if it would increase the value above the initial value.

Bounded semapthores support the *context management protocol*.

This class is *not thread safe*.

Using locks, conditions and semaphores in the `async with` statement

Lock, *Condition*, *Semaphore*, and *BoundedSemaphore* objects can be used in `async with` statements.

The `acquire()` method will be called when the block is entered, and `release()` will be called when the block is exited. Hence, the following snippet:

```
async with lock:
    # do something...
```

is equivalent to:

```
await lock.acquire()
try:
    # do something...
finally:
    lock.release()
```

Deprecated since version 3.7: Lock acquiring using `await lock` or `yield from lock` and `with` statement (`with await lock`, `with (yield from lock)`) are deprecated.

19.5.8 Queues

Source code: Lib/asyncio/queues.py

Queues:

- *Queue*
- *PriorityQueue*
- *LifoQueue*

asyncio queue API was designed to be close to classes of the *queue* module (*Queue*, *PriorityQueue*, *LifoQueue*), but it has no *timeout* parameter. The *asyncio.wait_for()* function can be used to cancel a task after a timeout.

Queue

class asyncio.Queue(*maxsize=0*, ***, *loop=None*)

A queue, useful for coordinating producer and consumer coroutines.

If *maxsize* is less than or equal to zero, the queue size is infinite. If it is an integer greater than `0`, then `await put()` will block when the queue reaches *maxsize*, until an item is removed by *get()*.

Unlike the standard library *queue*, you can reliably know this Queue's size with *qsize()*, since your single-threaded asyncio application won't be interrupted between calling *qsize()* and doing an operation on the Queue.

This class is *not thread safe*.

Changed in version 3.4.4: New *join()* and *task_done()* methods.

empty()

Return `True` if the queue is empty, `False` otherwise.

full()

Return `True` if there are *maxsize* items in the queue.

> **Note:** If the Queue was initialized with `maxsize=0` (the default), then *full()* is never `True`.

coroutine get()

Remove and return an item from the queue. If queue is empty, wait until an item is available.

This method is a *coroutine*.

See also:

The *empty()* method.

get_nowait()

Remove and return an item from the queue.

Return an item if one is immediately available, else raise *QueueEmpty*.

coroutine join()

Block until all items in the queue have been gotten and processed.

The count of unfinished tasks goes up whenever an item is added to the queue. The count goes down whenever a consumer thread calls *task_done()* to indicate that the item was retrieved and all work on it is complete. When the count of unfinished tasks drops to zero, *join()* unblocks.

This method is a *coroutine*.

New in version 3.4.4.

coroutine put(*item*)
Put an item into the queue. If the queue is full, wait until a free slot is available before adding item.

This method is a *coroutine*.

See also:

The *full()* method.

put_nowait(*item*)
Put an item into the queue without blocking.

If no free slot is immediately available, raise *QueueFull*.

qsize()
Number of items in the queue.

task_done()
Indicate that a formerly enqueued task is complete.

Used by queue consumers. For each *get()* used to fetch a task, a subsequent call to *task_done()* tells the queue that the processing on the task is complete.

If a *join()* is currently blocking, it will resume when all items have been processed (meaning that a *task_done()* call was received for every item that had been *put()* into the queue).

Raises *ValueError* if called more times than there were items placed in the queue.

New in version 3.4.4.

maxsize
Number of items allowed in the queue.

PriorityQueue

class asyncio.PriorityQueue
A subclass of *Queue*; retrieves entries in priority order (lowest first).

Entries are typically tuples of the form: (priority number, data).

LifoQueue

class asyncio.LifoQueue
A subclass of *Queue* that retrieves most recently added entries first.

Exceptions

exception asyncio.QueueEmpty
Exception raised when the *get_nowait()* method is called on a *Queue* object which is empty.

exception asyncio.QueueFull
Exception raised when the *put_nowait()* method is called on a *Queue* object which is full.

19.5.9 Develop with asyncio

Asynchronous programming is different than classical "sequential" programming. This page lists common traps and explains how to avoid them.

Debug mode of asyncio

The implementation of *asyncio* has been written for performance. In order to ease the development of asynchronous code, you may wish to enable *debug mode*.

To enable all debug checks for an application:

- Enable the asyncio debug mode globally by setting the environment variable `PYTHONASYNCIODEBUG` to `1`, using `-X dev` command line option (see the `-X` option), or by calling *AbstractEventLoop.set_debug()*.
- Set the log level of the *asyncio logger* to `logging.DEBUG`. For example, call `logging.basicConfig(level=logging.DEBUG)` at startup.
- Configure the *warnings* module to display *ResourceWarning* warnings. For example, use the `-Wdefault` command line option of Python to display them.

Examples debug checks:

- Log *coroutines defined but never "yielded from"*
- *call_soon()* and *call_at()* methods raise an exception if they are called from the wrong thread.
- Log the execution time of the selector
- Log callbacks taking more than 100 ms to be executed. The `AbstractEventLoop.slow_callback_duration` attribute is the minimum duration in seconds of "slow" callbacks.
- *ResourceWarning* warnings are emitted when transports and event loops are *not closed explicitly*.

Changed in version 3.7: The new `-X dev` command line option can now also be used to enable the debug mode.

See also:

The *AbstractEventLoop.set_debug()* method and the *asyncio logger*.

Cancellation

Cancellation of tasks is not common in classic programming. In asynchronous programming, not only is it something common, but you have to prepare your code to handle it.

Futures and tasks can be cancelled explicitly with their *Future.cancel()* method. The *wait_for()* function cancels the waited task when the timeout occurs. There are many other cases where a task can be cancelled indirectly.

Don't call *set_result()* or *set_exception()* method of *Future* if the future is cancelled: it would fail with an exception. For example, write:

```
if not fut.cancelled():
    fut.set_result('done')
```

Don't schedule directly a call to the *set_result()* or the *set_exception()* method of a future with *AbstractEventLoop.call_soon()*: the future can be cancelled before its method is called.

If you wait for a future, you should check early if the future was cancelled to avoid useless operations. Example:

```
async def slow_operation(fut):
    if fut.cancelled():
        return
    # ... slow computation ...
    await fut
    # ...
```

The *shield()* function can also be used to ignore cancellation.

Concurrency and multithreading

An event loop runs in a thread and executes all callbacks and tasks in the same thread. While a task is running in the event loop, no other task is running in the same thread. But when the task uses `await`, the task is suspended and the event loop executes the next task.

To schedule a callback from a different thread, the *AbstractEventLoop.call_soon_threadsafe()* method should be used. Example:

```
loop.call_soon_threadsafe(callback, *args)
```

Most asyncio objects are not thread safe. You should only worry if you access objects outside the event loop. For example, to cancel a future, don't call directly its *Future.cancel()* method, but:

```
loop.call_soon_threadsafe(fut.cancel)
```

To handle signals and to execute subprocesses, the event loop must be run in the main thread.

To schedule a coroutine object from a different thread, the *run_coroutine_threadsafe()* function should be used. It returns a *concurrent.futures.Future* to access the result:

```
future = asyncio.run_coroutine_threadsafe(coro_func(), loop)
result = future.result(timeout)  # Wait for the result with a timeout
```

The *AbstractEventLoop.run_in_executor()* method can be used with a thread pool executor to execute a callback in different thread to not block the thread of the event loop.

See also:

The *Synchronization primitives* section describes ways to synchronize tasks.

The *Subprocess and threads* section lists asyncio limitations to run subprocesses from different threads.

Handle blocking functions correctly

Blocking functions should not be called directly. For example, if a function blocks for 1 second, other tasks are delayed by 1 second which can have an important impact on reactivity.

For networking and subprocesses, the *asyncio* module provides high-level APIs like *protocols*.

An executor can be used to run a task in a different thread or even in a different process, to not block the thread of the event loop. See the *AbstractEventLoop.run_in_executor()* method.

See also:

The *Delayed calls* section details how the event loop handles time.

Logging

The *asyncio* module logs information with the *logging* module in the logger `'asyncio'`.

The default log level for the *asyncio* module is `logging.INFO`. For those not wanting such verbosity from *asyncio* the log level can be changed. For example, to change the level to `logging.WARNING`:

```
logging.getLogger('asyncio').setLevel(logging.WARNING)
```

Detect coroutine objects never scheduled

When a coroutine function is called and its result is not passed to *ensure_future()* or to the *AbstractEventLoop.create_task()* method, the execution of the coroutine object will never be scheduled which is probably a bug. *Enable the debug mode of asyncio* to *log a warning* to detect it.

Example with the bug:

```
import asyncio

async def test():
    print("never scheduled")

test()
```

Output in debug mode:

```
Coroutine test() at test.py:3 was never yielded from
Coroutine object created at (most recent call last):
  File "test.py", line 7, in <module>
    test()
```

The fix is to call the *ensure_future()* function or the *AbstractEventLoop.create_task()* method with the coroutine object.

See also:

Pending task destroyed.

Detect exceptions never consumed

Python usually calls *sys.excepthook()* on unhandled exceptions. If *Future.set_exception()* is called, but the exception is never consumed, *sys.excepthook()* is not called. Instead, *a log is emitted* when the future is deleted by the garbage collector, with the traceback where the exception was raised.

Example of unhandled exception:

```
import asyncio

@asyncio.coroutine
def bug():
    raise Exception("not consumed")

loop = asyncio.get_event_loop()
asyncio.ensure_future(bug())
loop.run_forever()
loop.close()
```

Output:

```
Task exception was never retrieved
future: <Task finished coro=<coro() done, defined at asyncio/coroutines.py:139>␣
↪exception=Exception('not consumed',)>
Traceback (most recent call last):
  File "asyncio/tasks.py", line 237, in _step
    result = next(coro)
  File "asyncio/coroutines.py", line 141, in coro
    res = func(*args, **kw)
```

(continues on next page)

(continued from previous page)

```
  File "test.py", line 5, in bug
    raise Exception("not consumed")
Exception: not consumed
```

Enable the debug mode of asyncio to get the traceback where the task was created. Output in debug mode:

```
Task exception was never retrieved
future: <Task finished coro=<bug() done, defined at test.py:3> exception=Exception('not consumed',
↪) created at test.py:8>
source_traceback: Object created at (most recent call last):
  File "test.py", line 8, in <module>
    asyncio.ensure_future(bug())
Traceback (most recent call last):
  File "asyncio/tasks.py", line 237, in _step
    result = next(coro)
  File "asyncio/coroutines.py", line 79, in __next__
    return next(self.gen)
  File "asyncio/coroutines.py", line 141, in coro
    res = func(*args, **kw)
  File "test.py", line 5, in bug
    raise Exception("not consumed")
Exception: not consumed
```

There are different options to fix this issue. The first option is to chain the coroutine in another coroutine and use classic try/except:

```
async def handle_exception():
    try:
        await bug()
    except Exception:
        print("exception consumed")

loop = asyncio.get_event_loop()
asyncio.ensure_future(handle_exception())
loop.run_forever()
loop.close()
```

Another option is to use the *AbstractEventLoop.run_until_complete()* function:

```
task = asyncio.ensure_future(bug())
try:
    loop.run_until_complete(task)
except Exception:
    print("exception consumed")
```

See also:

The *Future.exception()* method.

Chain coroutines correctly

When a coroutine function calls other coroutine functions and tasks, they should be chained explicitly with `await`. Otherwise, the execution is not guaranteed to be sequential.

Example with different bugs using *asyncio.sleep()* to simulate slow operations:

```
import asyncio

async def create():
    await asyncio.sleep(3.0)
    print("(1) create file")

async def write():
    await asyncio.sleep(1.0)
    print("(2) write into file")

async def close():
    print("(3) close file")

async def test():
    asyncio.ensure_future(create())
    asyncio.ensure_future(write())
    asyncio.ensure_future(close())
    await asyncio.sleep(2.0)
    loop.stop()

loop = asyncio.get_event_loop()
asyncio.ensure_future(test())
loop.run_forever()
print("Pending tasks at exit: %s" % asyncio.Task.all_tasks(loop))
loop.close()
```

Expected output:

```
(1) create file
(2) write into file
(3) close file
Pending tasks at exit: set()
```

Actual output:

```
(3) close file
(2) write into file
Pending tasks at exit: {<Task pending create() at test.py:7 wait_for=<Future pending cb=[Task._
↪wakeup()]>>}
Task was destroyed but it is pending!
task: <Task pending create() done at test.py:5 wait_for=<Future pending cb=[Task._wakeup()]>>
```

The loop stopped before the `create()` finished, `close()` has been called before `write()`, whereas coroutine functions were called in this order: `create()`, `write()`, `close()`.

To fix the example, tasks must be marked with `await`:

```
async def test():
    await asyncio.ensure_future(create())
    await asyncio.ensure_future(write())
    await asyncio.ensure_future(close())
    await asyncio.sleep(2.0)
    loop.stop()
```

Or without `asyncio.ensure_future()`:

```
async def test():
    await create()
```

(continues on next page)

(continued from previous page)

```
    await write()
    await close()
    await asyncio.sleep(2.0)
    loop.stop()
```

Pending task destroyed

If a pending task is destroyed, the execution of its wrapped *coroutine* did not complete. It is probably a bug and so a warning is logged.

Example of log:

```
Task was destroyed but it is pending!
task: <Task pending coro=<kill_me() done, defined at test.py:5> wait_for=<Future pending cb=[Task._
↪wakeup()]>>
```

Enable the debug mode of asyncio to get the traceback where the task was created. Example of log in debug mode:

```
Task was destroyed but it is pending!
source_traceback: Object created at (most recent call last):
  File "test.py", line 15, in <module>
    task = asyncio.ensure_future(coro, loop=loop)
task: <Task pending coro=<kill_me() done, defined at test.py:5> wait_for=<Future pending cb=[Task._
↪wakeup()] created at test.py:7> created at test.py:15>
```

See also:

Detect coroutine objects never scheduled.

Close transports and event loops

When a transport is no more needed, call its `close()` method to release resources. Event loops must also be closed explicitly.

If a transport or an event loop is not closed explicitly, a *ResourceWarning* warning will be emitted in its destructor. By default, *ResourceWarning* warnings are ignored. The *Debug mode of asyncio* section explains how to display them.

See also:

The *asyncio* module was designed in **PEP 3156**. For a motivational primer on transports and protocols, see **PEP 3153**.

19.6 asyncore — Asynchronous socket handler

Source code: Lib/asyncore.py

Deprecated since version 3.6: Please use *asyncio* instead.

Note: This module exists for backwards compatibility only. For new code we recommend using *asyncio*.

This module provides the basic infrastructure for writing asynchronous socket service clients and servers.

There are only two ways to have a program on a single processor do "more than one thing at a time." Multi-threaded programming is the simplest and most popular way to do it, but there is another very different technique, that lets you have nearly all the advantages of multi-threading, without actually using multiple threads. It's really only practical if your program is largely I/O bound. If your program is processor bound, then pre-emptive scheduled threads are probably what you really need. Network servers are rarely processor bound, however.

If your operating system supports the `select()` system call in its I/O library (and nearly all do), then you can use it to juggle multiple communication channels at once; doing other work while your I/O is taking place in the "background." Although this strategy can seem strange and complex, especially at first, it is in many ways easier to understand and control than multi-threaded programming. The *asyncore* module solves many of the difficult problems for you, making the task of building sophisticated high-performance network servers and clients a snap. For "conversational" applications and protocols the companion *asynchat* module is invaluable.

The basic idea behind both modules is to create one or more network *channels*, instances of class *asyncore.dispatcher* and *asynchat.async_chat*. Creating the channels adds them to a global map, used by the *loop()* function if you do not provide it with your own *map*.

Once the initial channel(s) is(are) created, calling the *loop()* function activates channel service, which continues until the last channel (including any that have been added to the map during asynchronous service) is closed.

`asyncore.loop`([*timeout*[, *use_poll*[, *map*[, *count*]]]])

Enter a polling loop that terminates after count passes or all open channels have been closed. All arguments are optional. The *count* parameter defaults to `None`, resulting in the loop terminating only when all channels have been closed. The *timeout* argument sets the timeout parameter for the appropriate *select()* or *poll()* call, measured in seconds; the default is 30 seconds. The *use_poll* parameter, if true, indicates that *poll()* should be used in preference to *select()* (the default is `False`).

The *map* parameter is a dictionary whose items are the channels to watch. As channels are closed they are deleted from their map. If *map* is omitted, a global map is used. Channels (instances of *asyncore.dispatcher*, *asynchat.async_chat* and subclasses thereof) can freely be mixed in the map.

`class asyncore.dispatcher`

The *dispatcher* class is a thin wrapper around a low-level socket object. To make it more useful, it has a few methods for event-handling which are called from the asynchronous loop. Otherwise, it can be treated as a normal non-blocking socket object.

The firing of low-level events at certain times or in certain connection states tells the asynchronous loop that certain higher-level events have taken place. For example, if we have asked for a socket to connect to another host, we know that the connection has been made when the socket becomes writable for the first time (at this point you know that you may write to it with the expectation of success). The implied higher-level events are:

Event	Description
`handle_connect()`	Implied by the first read or write event
`handle_close()`	Implied by a read event with no data available
`handle_accepted()`	Implied by a read event on a listening socket

During asynchronous processing, each mapped channel's *readable()* and *writable()* methods are used to determine whether the channel's socket should be added to the list of channels `select()`ed or `poll()`ed for read and write events.

Thus, the set of channel events is larger than the basic socket events. The full set of methods that can be overridden in your subclass follows:

handle_read()
Called when the asynchronous loop detects that a `read()` call on the channel's socket will succeed.

handle_write()
Called when the asynchronous loop detects that a writable socket can be written. Often this method will implement the necessary buffering for performance. For example:

```
def handle_write(self):
    sent = self.send(self.buffer)
    self.buffer = self.buffer[sent:]
```

handle_expt()
Called when there is out of band (OOB) data for a socket connection. This will almost never happen, as OOB is tenuously supported and rarely used.

handle_connect()
Called when the active opener's socket actually makes a connection. Might send a "welcome" banner, or initiate a protocol negotiation with the remote endpoint, for example.

handle_close()
Called when the socket is closed.

handle_error()
Called when an exception is raised and not otherwise handled. The default version prints a condensed traceback.

handle_accept()
Called on listening channels (passive openers) when a connection can be established with a new remote endpoint that has issued a *connect()* call for the local endpoint. Deprecated in version 3.2; use *handle_accepted()* instead.

Deprecated since version 3.2.

handle_accepted(*sock*, *addr*)
Called on listening channels (passive openers) when a connection has been established with a new remote endpoint that has issued a *connect()* call for the local endpoint. *sock* is a *new* socket object usable to send and receive data on the connection, and *addr* is the address bound to the socket on the other end of the connection.

New in version 3.2.

readable()
Called each time around the asynchronous loop to determine whether a channel's socket should be added to the list on which read events can occur. The default method simply returns `True`, indicating that by default, all channels will be interested in read events.

writable()
Called each time around the asynchronous loop to determine whether a channel's socket should be added to the list on which write events can occur. The default method simply returns `True`, indicating that by default, all channels will be interested in write events.

In addition, each channel delegates or extends many of the socket methods. Most of these are nearly identical to their socket partners.

create_socket(*family=socket.AF_INET*, *type=socket.SOCK_STREAM*)
This is identical to the creation of a normal socket, and will use the same options for creation. Refer to the *socket* documentation for information on creating sockets.

Changed in version 3.3: *family* and *type* arguments can be omitted.

connect(*address*)
As with the normal socket object, *address* is a tuple with the first element the host to connect to, and the second the port number.

send(*data*)
Send *data* to the remote end-point of the socket.

recv(*buffer_size*)
Read at most *buffer_size* bytes from the socket's remote end-point. An empty bytes object implies that the channel has been closed from the other end.

Note that *recv()* may raise *BlockingIOError* , even though *select.select()* or *select.poll()* has reported the socket ready for reading.

listen(*backlog*)
Listen for connections made to the socket. The *backlog* argument specifies the maximum number of queued connections and should be at least 1; the maximum value is system-dependent (usually 5).

bind(*address*)
Bind the socket to *address*. The socket must not already be bound. (The format of *address* depends on the address family — refer to the *socket* documentation for more information.) To mark the socket as re-usable (setting the `SO_REUSEADDR` option), call the *dispatcher* object's `set_reuse_addr()` method.

accept()
Accept a connection. The socket must be bound to an address and listening for connections. The return value can be either `None` or a pair `(conn, address)` where *conn* is a *new* socket object usable to send and receive data on the connection, and *address* is the address bound to the socket on the other end of the connection. When `None` is returned it means the connection didn't take place, in which case the server should just ignore this event and keep listening for further incoming connections.

close()
Close the socket. All future operations on the socket object will fail. The remote end-point will receive no more data (after queued data is flushed). Sockets are automatically closed when they are garbage-collected.

class asyncore.dispatcher_with_send
A *dispatcher* subclass which adds simple buffered output capability, useful for simple clients. For more sophisticated usage use *asynchat.async_chat*.

class asyncore.file_dispatcher
A file_dispatcher takes a file descriptor or *file object* along with an optional map argument and wraps it for use with the `poll()` or `loop()` functions. If provided a file object or anything with a `fileno()` method, that method will be called and passed to the *file_wrapper* constructor. Availability: UNIX.

class asyncore.file_wrapper
A file_wrapper takes an integer file descriptor and calls *os.dup()* to duplicate the handle so that the original handle may be closed independently of the file_wrapper. This class implements sufficient methods to emulate a socket for use by the *file_dispatcher* class. Availability: UNIX.

19.6.1 asyncore Example basic HTTP client

Here is a very basic HTTP client that uses the *dispatcher* class to implement its socket handling:

```
import asyncore

class HTTPClient(asyncore.dispatcher):

    def __init__(self, host, path):
        asyncore.dispatcher.__init__(self)
```

(continues on next page)

(continued from previous page)

```
        self.create_socket()
        self.connect( (host, 80) )
        self.buffer = bytes('GET %s HTTP/1.0\r\nHost: %s\r\n\r\n' %
                            (path, host), 'ascii')

    def handle_connect(self):
        pass

    def handle_close(self):
        self.close()

    def handle_read(self):
        print(self.recv(8192))

    def writable(self):
        return (len(self.buffer) > 0)

    def handle_write(self):
        sent = self.send(self.buffer)
        self.buffer = self.buffer[sent:]

client = HTTPClient('www.python.org', '/')
asyncore.loop()
```

19.6.2 asyncore Example basic echo server

Here is a basic echo server that uses the *dispatcher* class to accept connections and dispatches the incoming connections to a handler:

```
import asyncore

class EchoHandler(asyncore.dispatcher_with_send):

    def handle_read(self):
        data = self.recv(8192)
        if data:
            self.send(data)

class EchoServer(asyncore.dispatcher):

    def __init__(self, host, port):
        asyncore.dispatcher.__init__(self)
        self.create_socket()
        self.set_reuse_addr()
        self.bind((host, port))
        self.listen(5)

    def handle_accepted(self, sock, addr):
        print('Incoming connection from %s' % repr(addr))
        handler = EchoHandler(sock)

server = EchoServer('localhost', 8080)
asyncore.loop()
```

19.7 asynchat — Asynchronous socket command/response handler

Source code: Lib/asynchat.py

Deprecated since version 3.6: Please use *asyncio* instead.

Note: This module exists for backwards compatibility only. For new code we recommend using *asyncio*.

This module builds on the *asyncore* infrastructure, simplifying asynchronous clients and servers and making it easier to handle protocols whose elements are terminated by arbitrary strings, or are of variable length. *asynchat* defines the abstract class *async_chat* that you subclass, providing implementations of the `collect_incoming_data()` and `found_terminator()` methods. It uses the same asynchronous loop as *asyncore*, and the two types of channel, *asyncore.dispatcher* and *asynchat.async_chat*, can freely be mixed in the channel map. Typically an *asyncore.dispatcher* server channel generates new *asynchat.async_chat* channel objects as it receives incoming connection requests.

class asynchat.async_chat

This class is an abstract subclass of *asyncore.dispatcher*. To make practical use of the code you must subclass *async_chat*, providing meaningful *collect_incoming_data()* and *found_terminator()* methods. The *asyncore.dispatcher* methods can be used, although not all make sense in a message/response context.

Like *asyncore.dispatcher*, *async_chat* defines a set of events that are generated by an analysis of socket conditions after a `select()` call. Once the polling loop has been started the *async_chat* object's methods are called by the event-processing framework with no action on the part of the programmer.

Two class attributes can be modified, to improve performance, or possibly even to conserve memory.

ac_in_buffer_size

The asynchronous input buffer size (default `4096`).

ac_out_buffer_size

The asynchronous output buffer size (default `4096`).

Unlike *asyncore.dispatcher*, *async_chat* allows you to define a FIFO queue of *producers*. A producer need have only one method, `more()`, which should return data to be transmitted on the channel. The producer indicates exhaustion (*i.e.* that it contains no more data) by having its `more()` method return the empty bytes object. At this point the *async_chat* object removes the producer from the queue and starts using the next producer, if any. When the producer queue is empty the `handle_write()` method does nothing. You use the channel object's *set_terminator()* method to describe how to recognize the end of, or an important breakpoint in, an incoming transmission from the remote endpoint.

To build a functioning *async_chat* subclass your input methods *collect_incoming_data()* and *found_terminator()* must handle the data that the channel receives asynchronously. The methods are described below.

async_chat.close_when_done()

Pushes a `None` on to the producer queue. When this producer is popped off the queue it causes the channel to be closed.

async_chat.collect_incoming_data(*data*)

Called with *data* holding an arbitrary amount of received data. The default method, which must be overridden, raises a *NotImplementedError* exception.

async_chat.discard_buffers()

In emergencies this method will discard any data held in the input and/or output buffers and the producer queue.

async_chat.found_terminator()
: Called when the incoming data stream matches the termination condition set by *set_terminator()*. The default method, which must be overridden, raises a *NotImplementedError* exception. The buffered input data should be available via an instance attribute.

async_chat.get_terminator()
: Returns the current terminator for the channel.

async_chat.push(*data*)
: Pushes data on to the channel's queue to ensure its transmission. This is all you need to do to have the channel write the data out to the network, although it is possible to use your own producers in more complex schemes to implement encryption and chunking, for example.

async_chat.push_with_producer(*producer*)
: Takes a producer object and adds it to the producer queue associated with the channel. When all currently-pushed producers have been exhausted the channel will consume this producer's data by calling its `more()` method and send the data to the remote endpoint.

async_chat.set_terminator(*term*)
: Sets the terminating condition to be recognized on the channel. `term` may be any of three types of value, corresponding to three different ways to handle incoming protocol data.

term	Description
string	Will call *found_terminator()* when the string is found in the input stream
integer	Will call *found_terminator()* when the indicated number of characters have been received
`None`	The channel continues to collect data forever

Note that any data following the terminator will be available for reading by the channel after *found_terminator()* is called.

19.7.1 asynchat Example

The following partial example shows how HTTP requests can be read with *async_chat*. A web server might create an `http_request_handler` object for each incoming client connection. Notice that initially the channel terminator is set to match the blank line at the end of the HTTP headers, and a flag indicates that the headers are being read.

Once the headers have been read, if the request is of type POST (indicating that further data are present in the input stream) then the `Content-Length:` header is used to set a numeric terminator to read the right amount of data from the channel.

The `handle_request()` method is called once all relevant input has been marshalled, after setting the channel terminator to `None` to ensure that any extraneous data sent by the web client are ignored.

```
import asynchat

class http_request_handler(asynchat.async_chat):

    def __init__(self, sock, addr, sessions, log):
        asynchat.async_chat.__init__(self, sock=sock)
        self.addr = addr
        self.sessions = sessions
        self.ibuffer = []
        self.obuffer = b""
        self.set_terminator(b"\r\n\r\n")
        self.reading_headers = True
```

(continues on next page)

(continued from previous page)

```
        self.handling = False
        self.cgi_data = None
        self.log = log

    def collect_incoming_data(self, data):
        """Buffer the data"""
        self.ibuffer.append(data)

    def found_terminator(self):
        if self.reading_headers:
            self.reading_headers = False
            self.parse_headers(b"".join(self.ibuffer))
            self.ibuffer = []
            if self.op.upper() == b"POST":
                clen = self.headers.getheader("content-length")
                self.set_terminator(int(clen))
            else:
                self.handling = True
                self.set_terminator(None)
                self.handle_request()
        elif not self.handling:
            self.set_terminator(None)  # browsers sometimes over-send
            self.cgi_data = parse(self.headers, b"".join(self.ibuffer))
            self.handling = True
            self.ibuffer = []
            self.handle_request()
```

19.8 `signal` — Set handlers for asynchronous events

This module provides mechanisms to use signal handlers in Python.

19.8.1 General rules

The *`signal.signal()`* function allows defining custom handlers to be executed when a signal is received. A small number of default handlers are installed: `SIGPIPE` is ignored (so write errors on pipes and sockets can be reported as ordinary Python exceptions) and `SIGINT` is translated into a *`KeyboardInterrupt`* exception.

A handler for a particular signal, once set, remains installed until it is explicitly reset (Python emulates the BSD style interface regardless of the underlying implementation), with the exception of the handler for `SIGCHLD`, which follows the underlying implementation.

Execution of Python signal handlers

A Python signal handler does not get executed inside the low-level (C) signal handler. Instead, the low-level signal handler sets a flag which tells the *virtual machine* to execute the corresponding Python signal handler at a later point(for example at the next *bytecode* instruction). This has consequences:

- It makes little sense to catch synchronous errors like `SIGFPE` or `SIGSEGV` that are caused by an invalid operation in C code. Python will return from the signal handler to the C code, which is likely to raise the same signal again, causing Python to apparently hang. From Python 3.3 onwards, you can use the *`faulthandler`* module to report on synchronous errors.

- A long-running calculation implemented purely in C (such as regular expression matching on a large body of text) may run uninterrupted for an arbitrary amount of time, regardless of any signals received. The Python signal handlers will be called when the calculation finishes.

Signals and threads

Python signal handlers are always executed in the main Python thread, even if the signal was received in another thread. This means that signals can't be used as a means of inter-thread communication. You can use the synchronization primitives from the *threading* module instead.

Besides, only the main thread is allowed to set a new signal handler.

19.8.2 Module contents

Changed in version 3.5: signal (SIG*), handler (*SIG_DFL*, *SIG_IGN*) and sigmask (*SIG_BLOCK*, *SIG_UNBLOCK*, *SIG_SETMASK*) related constants listed below were turned into *enums*. *getsignal()*, *pthread_sigmask()*, *sigpending()* and *sigwait()* functions return human-readable *enums*.

The variables defined in the *signal* module are:

`signal.SIG_DFL`
: This is one of two standard signal handling options; it will simply perform the default function for the signal. For example, on most systems the default action for `SIGQUIT` is to dump core and exit, while the default action for `SIGCHLD` is to simply ignore it.

`signal.SIG_IGN`
: This is another standard signal handler, which will simply ignore the given signal.

`SIG*`
: All the signal numbers are defined symbolically. For example, the hangup signal is defined as `signal.SIGHUP`; the variable names are identical to the names used in C programs, as found in `<signal.h>`. The Unix man page for '`signal()`' lists the existing signals (on some systems this is *signal(2)*, on others the list is in *signal(7)*). Note that not all systems define the same set of signal names; only those names defined by the system are defined by this module.

`signal.CTRL_C_EVENT`
: The signal corresponding to the `Ctrl+C` keystroke event. This signal can only be used with *os.kill()*.

  Availability: Windows.

  New in version 3.2.

`signal.CTRL_BREAK_EVENT`
: The signal corresponding to the `Ctrl+Break` keystroke event. This signal can only be used with *os.kill()*.

  Availability: Windows.

  New in version 3.2.

`signal.NSIG`
: One more than the number of the highest signal number.

`signal.ITIMER_REAL`
: Decrements interval timer in real time, and delivers `SIGALRM` upon expiration.

`signal.ITIMER_VIRTUAL`
: Decrements interval timer only when the process is executing, and delivers SIGVTALRM upon expiration.

signal.ITIMER_PROF
: Decrements interval timer both when the process executes and when the system is executing on behalf of the process. Coupled with ITIMER_VIRTUAL, this timer is usually used to profile the time spent by the application in user and kernel space. SIGPROF is delivered upon expiration.

signal.SIG_BLOCK
: A possible value for the *how* parameter to *pthread_sigmask()* indicating that signals are to be blocked.

  New in version 3.3.

signal.SIG_UNBLOCK
: A possible value for the *how* parameter to *pthread_sigmask()* indicating that signals are to be unblocked.

  New in version 3.3.

signal.SIG_SETMASK
: A possible value for the *how* parameter to *pthread_sigmask()* indicating that the signal mask is to be replaced.

  New in version 3.3.

The *signal* module defines one exception:

exception signal.ItimerError
: Raised to signal an error from the underlying *setitimer()* or *getitimer()* implementation. Expect this error if an invalid interval timer or a negative time is passed to *setitimer()*. This error is a subtype of *OSError*.

  New in version 3.3: This error used to be a subtype of *IOError*, which is now an alias of *OSError*.

The *signal* module defines the following functions:

signal.alarm(*time*)
: If *time* is non-zero, this function requests that a SIGALRM signal be sent to the process in *time* seconds. Any previously scheduled alarm is canceled (only one alarm can be scheduled at any time). The returned value is then the number of seconds before any previously set alarm was to have been delivered. If *time* is zero, no alarm is scheduled, and any scheduled alarm is canceled. If the return value is zero, no alarm is currently scheduled. (See the Unix man page *alarm(2)*.) Availability: Unix.

signal.getsignal(*signalnum*)
: Return the current signal handler for the signal *signalnum*. The returned value may be a callable Python object, or one of the special values *signal.SIG_IGN*, *signal.SIG_DFL* or *None*. Here, *signal.SIG_IGN* means that the signal was previously ignored, *signal.SIG_DFL* means that the default way of handling the signal was previously in use, and None means that the previous signal handler was not installed from Python.

signal.pause()
: Cause the process to sleep until a signal is received; the appropriate handler will then be called. Returns nothing. Not on Windows. (See the Unix man page *signal(2)*.)

  See also *sigwait()*, *sigwaitinfo()*, *sigtimedwait()* and *sigpending()*.

signal.pthread_kill(*thread_id*, *signalnum*)
: Send the signal *signalnum* to the thread *thread_id*, another thread in the same process as the caller. The target thread can be executing any code (Python or not). However, if the target thread is executing the Python interpreter, the Python signal handlers will be *executed by the main thread*. Therefore, the only point of sending a signal to a particular Python thread would be to force a running system call to fail with *InterruptedError*.

  Use *threading.get_ident()* or the *ident* attribute of *threading.Thread* objects to get a suitable value for *thread_id*.

If *signalnum* is 0, then no signal is sent, but error checking is still performed; this can be used to check if the target thread is still running.

Availability: Unix (see the man page *pthread_kill(3)* for further information).

See also *os.kill()*.

New in version 3.3.

signal.**pthread_sigmask**(*how*, *mask*)
Fetch and/or change the signal mask of the calling thread. The signal mask is the set of signals whose delivery is currently blocked for the caller. Return the old signal mask as a set of signals.

The behavior of the call is dependent on the value of *how*, as follows.

- *SIG_BLOCK*: The set of blocked signals is the union of the current set and the *mask* argument.
- *SIG_UNBLOCK*: The signals in *mask* are removed from the current set of blocked signals. It is permissible to attempt to unblock a signal which is not blocked.
- *SIG_SETMASK*: The set of blocked signals is set to the *mask* argument.

mask is a set of signal numbers (e.g. {`signal.SIGINT`, `signal.SIGTERM`}). Use `range(1, signal.NSIG)` for a full mask including all signals.

For example, `signal.pthread_sigmask(signal.SIG_BLOCK, [])` reads the signal mask of the calling thread.

Availability: Unix. See the man page *sigprocmask(3)* and *pthread_sigmask(3)* for further information.

See also *pause()*, *sigpending()* and *sigwait()*.

New in version 3.3.

signal.**setitimer**(*which*, *seconds*, *interval=0.0*)
Sets given interval timer (one of *signal.ITIMER_REAL*, *signal.ITIMER_VIRTUAL* or *signal.ITIMER_PROF*) specified by *which* to fire after *seconds* (float is accepted, different from *alarm()*) and after that every *interval* seconds (if *interval* is non-zero). The interval timer specified by *which* can be cleared by setting *seconds* to zero.

When an interval timer fires, a signal is sent to the process. The signal sent is dependent on the timer being used; *signal.ITIMER_REAL* will deliver `SIGALRM`, *signal.ITIMER_VIRTUAL* sends `SIGVTALRM`, and *signal.ITIMER_PROF* will deliver `SIGPROF`.

The old values are returned as a tuple: (delay, interval).

Attempting to pass an invalid interval timer will cause an *ItimerError*. Availability: Unix.

signal.**getitimer**(*which*)
Returns current value of a given interval timer specified by *which*. Availability: Unix.

signal.**set_wakeup_fd**(*fd*, ***, *warn_on_full_buffer=True*)
Set the wakeup file descriptor to *fd*. When a signal is received, the signal number is written as a single byte into the fd. This can be used by a library to wakeup a poll or select call, allowing the signal to be fully processed.

The old wakeup fd is returned (or -1 if file descriptor wakeup was not enabled). If *fd* is -1, file descriptor wakeup is disabled. If not -1, *fd* must be non-blocking. It is up to the library to remove any bytes from *fd* before calling poll or select again.

When threads are enabled, this function can only be called from the main thread; attempting to call it from other threads will cause a *ValueError* exception to be raised.

There are two common ways to use this function. In both approaches, you use the fd to wake up when a signal arrives, but then they differ in how they determine *which* signal or signals have arrived.

In the first approach, we read the data out of the fd's buffer, and the byte values give you the signal numbers. This is simple, but in rare cases it can run into a problem: generally the fd will have a limited amount of buffer space, and if too many signals arrive too quickly, then the buffer may become full, and some signals may be lost. If you use this approach, then you should set `warn_on_full_buffer=True`, which will at least cause a warning to be printed to stderr when signals are lost.

In the second approach, we use the wakeup fd *only* for wakeups, and ignore the actual byte values. In this case, all we care about is whether the fd's buffer is empty or non-empty; a full buffer doesn't indicate a problem at all. If you use this approach, then you should set `warn_on_full_buffer=False`, so that your users are not confused by spurious warning messages.

Changed in version 3.5: On Windows, the function now also supports socket handles.

Changed in version 3.7: Added `warn_on_full_buffer` parameter.

`signal.siginterrupt`(*signalnum*, *flag*)

Change system call restart behaviour: if *flag* is *False*, system calls will be restarted when interrupted by signal *signalnum*, otherwise system calls will be interrupted. Returns nothing. Availability: Unix (see the man page *siginterrupt(3)* for further information).

Note that installing a signal handler with *signal()* will reset the restart behaviour to interruptible by implicitly calling `siginterrupt()` with a true *flag* value for the given signal.

`signal.signal`(*signalnum*, *handler*)

Set the handler for signal *signalnum* to the function *handler*. *handler* can be a callable Python object taking two arguments (see below), or one of the special values *signal.SIG_IGN* or *signal.SIG_DFL*. The previous signal handler will be returned (see the description of *getsignal()* above). (See the Unix man page *signal(2)*.)

When threads are enabled, this function can only be called from the main thread; attempting to call it from other threads will cause a *ValueError* exception to be raised.

The *handler* is called with two arguments: the signal number and the current stack frame (`None` or a frame object; for a description of frame objects, see the description in the type hierarchy or see the attribute descriptions in the *inspect* module).

On Windows, *signal()* can only be called with `SIGABRT`, `SIGFPE`, `SIGILL`, `SIGINT`, `SIGSEGV`, `SIGTERM`, or `SIGBREAK`. A *ValueError* will be raised in any other case. Note that not all systems define the same set of signal names; an *AttributeError* will be raised if a signal name is not defined as `SIG*` module level constant.

`signal.sigpending`()

Examine the set of signals that are pending for delivery to the calling thread (i.e., the signals which have been raised while blocked). Return the set of the pending signals.

Availability: Unix (see the man page *sigpending(2)* for further information).

See also *pause()*, *pthread_sigmask()* and *sigwait()*.

New in version 3.3.

`signal.sigwait`(*sigset*)

Suspend execution of the calling thread until the delivery of one of the signals specified in the signal set *sigset*. The function accepts the signal (removes it from the pending list of signals), and returns the signal number.

Availability: Unix (see the man page *sigwait(3)* for further information).

See also *pause()*, *pthread_sigmask()*, *sigpending()*, *sigwaitinfo()* and *sigtimedwait()*.

New in version 3.3.

`signal.sigwaitinfo`(*sigset*)

Suspend execution of the calling thread until the delivery of one of the signals specified in the signal

set *sigset*. The function accepts the signal and removes it from the pending list of signals. If one of the signals in *sigset* is already pending for the calling thread, the function will return immediately with information about that signal. The signal handler is not called for the delivered signal. The function raises an *InterruptedError* if it is interrupted by a signal that is not in *sigset*.

The return value is an object representing the data contained in the `siginfo_t` structure, namely: `si_signo`, `si_code`, `si_errno`, `si_pid`, `si_uid`, `si_status`, `si_band`.

Availability: Unix (see the man page *sigwaitinfo(2)* for further information).

See also *pause()*, *sigwait()* and *sigtimedwait()*.

New in version 3.3.

Changed in version 3.5: The function is now retried if interrupted by a signal not in *sigset* and the signal handler does not raise an exception (see **PEP 475** for the rationale).

`signal.sigtimedwait`(*sigset*, *timeout*)

Like *sigwaitinfo()*, but takes an additional *timeout* argument specifying a timeout. If *timeout* is specified as `0`, a poll is performed. Returns *None* if a timeout occurs.

Availability: Unix (see the man page *sigtimedwait(2)* for further information).

See also *pause()*, *sigwait()* and *sigwaitinfo()*.

New in version 3.3.

Changed in version 3.5: The function is now retried with the recomputed *timeout* if interrupted by a signal not in *sigset* and the signal handler does not raise an exception (see **PEP 475** for the rationale).

19.8.3 Example

Here is a minimal example program. It uses the *alarm()* function to limit the time spent waiting to open a file; this is useful if the file is for a serial device that may not be turned on, which would normally cause the *os.open()* to hang indefinitely. The solution is to set a 5-second alarm before opening the file; if the operation takes too long, the alarm signal will be sent, and the handler raises an exception.

```
import signal, os

def handler(signum, frame):
    print('Signal handler called with signal', signum)
    raise OSError("Couldn't open device!")

# Set the signal handler and a 5-second alarm
signal.signal(signal.SIGALRM, handler)
signal.alarm(5)

# This open() may hang indefinitely
fd = os.open('/dev/ttyS0', os.O_RDWR)

signal.alarm(0)          # Disable the alarm
```

19.9 mmap — Memory-mapped file support

Memory-mapped file objects behave like both *bytearray* and like *file objects*. You can use mmap objects in most places where *bytearray* are expected; for example, you can use the *re* module to search through a memory-mapped file. You can also change a single byte by doing `obj[index] = 97`, or change a subsequence

by assigning to a slice: `obj[i1:i2] = b'...'`. You can also read and write data starting at the current file position, and `seek()` through the file to different positions.

A memory-mapped file is created by the *mmap* constructor, which is different on Unix and on Windows. In either case you must provide a file descriptor for a file opened for update. If you wish to map an existing Python file object, use its `fileno()` method to obtain the correct value for the *fileno* parameter. Otherwise, you can open the file using the *os.open()* function, which returns a file descriptor directly (the file still needs to be closed when done).

Note: If you want to create a memory-mapping for a writable, buffered file, you should *flush()* the file first. This is necessary to ensure that local modifications to the buffers are actually available to the mapping.

For both the Unix and Windows versions of the constructor, *access* may be specified as an optional keyword parameter. *access* accepts one of four values: `ACCESS_READ`, `ACCESS_WRITE`, or `ACCESS_COPY` to specify read-only, write-through or copy-on-write memory respectively, or `ACCESS_DEFAULT` to defer to *prot*. *access* can be used on both Unix and Windows. If *access* is not specified, Windows mmap returns a write-through mapping. The initial memory values for all three access types are taken from the specified file. Assignment to an `ACCESS_READ` memory map raises a *TypeError* exception. Assignment to an `ACCESS_WRITE` memory map affects both memory and the underlying file. Assignment to an `ACCESS_COPY` memory map affects memory but does not update the underlying file.

Changed in version 3.7: Added `ACCESS_DEFAULT` constant.

To map anonymous memory, -1 should be passed as the fileno along with the length.

class mmap.mmap(*fileno*, *length*, *tagname=None*, *access=ACCESS_DEFAULT*[, *offset*])

(Windows version) Maps *length* bytes from the file specified by the file handle *fileno*, and creates a mmap object. If *length* is larger than the current size of the file, the file is extended to contain *length* bytes. If *length* is `0`, the maximum length of the map is the current size of the file, except that if the file is empty Windows raises an exception (you cannot create an empty mapping on Windows).

tagname, if specified and not `None`, is a string giving a tag name for the mapping. Windows allows you to have many different mappings against the same file. If you specify the name of an existing tag, that tag is opened, otherwise a new tag of this name is created. If this parameter is omitted or `None`, the mapping is created without a name. Avoiding the use of the tag parameter will assist in keeping your code portable between Unix and Windows.

offset may be specified as a non-negative integer offset. mmap references will be relative to the offset from the beginning of the file. *offset* defaults to 0. *offset* must be a multiple of the ALLOCATIONGRANULARITY.

class mmap.mmap(*fileno*, *length*, *flags=MAP_SHARED*, *prot=PROT_WRITE|PROT_READ*, *access=ACCESS_DEFAULT*[, *offset*])

(Unix version) Maps *length* bytes from the file specified by the file descriptor *fileno*, and returns a mmap object. If *length* is `0`, the maximum length of the map will be the current size of the file when *mmap* is called.

flags specifies the nature of the mapping. `MAP_PRIVATE` creates a private copy-on-write mapping, so changes to the contents of the mmap object will be private to this process, and `MAP_SHARED` creates a mapping that's shared with all other processes mapping the same areas of the file. The default value is `MAP_SHARED`.

prot, if specified, gives the desired memory protection; the two most useful values are `PROT_READ` and `PROT_WRITE`, to specify that the pages may be read or written. *prot* defaults to `PROT_READ | PROT_WRITE`.

access may be specified in lieu of *flags* and *prot* as an optional keyword parameter. It is an error to specify both *flags*, *prot* and *access*. See the description of *access* above for information on how to use this parameter.

offset may be specified as a non-negative integer offset. mmap references will be relative to the offset from the beginning of the file. *offset* defaults to 0. *offset* must be a multiple of the PAGESIZE or ALLOCATIONGRANULARITY.

To ensure validity of the created memory mapping the file specified by the descriptor *fileno* is internally automatically synchronized with physical backing store on Mac OS X and OpenVMS.

This example shows a simple way of using *mmap*:

```
import mmap

# write a simple example file
with open("hello.txt", "wb") as f:
    f.write(b"Hello Python!\n")

with open("hello.txt", "r+b") as f:
    # memory-map the file, size 0 means whole file
    mm = mmap.mmap(f.fileno(), 0)
    # read content via standard file methods
    print(mm.readline())  # prints b"Hello Python!\n"
    # read content via slice notation
    print(mm[:5])  # prints b"Hello"
    # update content using slice notation;
    # note that new content must have same size
    mm[6:] = b" world!\n"
    # ... and read again using standard file methods
    mm.seek(0)
    print(mm.readline())  # prints b"Hello  world!\n"
    # close the map
    mm.close()
```

mmap can also be used as a context manager in a `with` statement:

```
import mmap

with mmap.mmap(-1, 13) as mm:
    mm.write(b"Hello world!")
```

New in version 3.2: Context manager support.

The next example demonstrates how to create an anonymous map and exchange data between the parent and child processes:

```
import mmap
import os

mm = mmap.mmap(-1, 13)
mm.write(b"Hello world!")

pid = os.fork()

if pid == 0:  # In a child process
    mm.seek(0)
    print(mm.readline())

    mm.close()
```

Memory-mapped file objects support the following methods:

`close()`

Closes the mmap. Subsequent calls to other methods of the object will result in a ValueError exception being raised. This will not close the open file.

`closed`
`True` if the file is closed.

New in version 3.2.

`find`(*sub*[, *start*[, *end*]])
Returns the lowest index in the object where the subsequence *sub* is found, such that *sub* is contained in the range [*start*, *end*]. Optional arguments *start* and *end* are interpreted as in slice notation. Returns `-1` on failure.

Changed in version 3.5: Writable *bytes-like object* is now accepted.

`flush`([*offset*[, *size*]])
Flushes changes made to the in-memory copy of a file back to disk. Without use of this call there is no guarantee that changes are written back before the object is destroyed. If *offset* and *size* are specified, only changes to the given range of bytes will be flushed to disk; otherwise, the whole extent of the mapping is flushed.

(Windows version) A nonzero value returned indicates success; zero indicates failure.

(Unix version) A zero value is returned to indicate success. An exception is raised when the call failed.

`move`(*dest*, *src*, *count*)
Copy the *count* bytes starting at offset *src* to the destination index *dest*. If the mmap was created with `ACCESS_READ`, then calls to move will raise a *TypeError* exception.

`read`([*n*])
Return a *bytes* containing up to *n* bytes starting from the current file position. If the argument is omitted, `None` or negative, return all bytes from the current file position to the end of the mapping. The file position is updated to point after the bytes that were returned.

Changed in version 3.3: Argument can be omitted or `None`.

`read_byte`()
Returns a byte at the current file position as an integer, and advances the file position by 1.

`readline`()
Returns a single line, starting at the current file position and up to the next newline.

`resize`(*newsize*)
Resizes the map and the underlying file, if any. If the mmap was created with `ACCESS_READ` or `ACCESS_COPY`, resizing the map will raise a *TypeError* exception.

`rfind`(*sub*[, *start*[, *end*]])
Returns the highest index in the object where the subsequence *sub* is found, such that *sub* is contained in the range [*start*, *end*]. Optional arguments *start* and *end* are interpreted as in slice notation. Returns `-1` on failure.

Changed in version 3.5: Writable *bytes-like object* is now accepted.

`seek`(*pos*[, *whence*])
Set the file's current position. *whence* argument is optional and defaults to `os.SEEK_SET` or `0` (absolute file positioning); other values are `os.SEEK_CUR` or `1` (seek relative to the current position) and `os.SEEK_END` or `2` (seek relative to the file's end).

`size`()
Return the length of the file, which can be larger than the size of the memory-mapped area.

`tell`()
Returns the current position of the file pointer.

write(*bytes*)
Write the bytes in *bytes* into memory at the current position of the file pointer and return the number of bytes written (never less than `len(bytes)`, since if the write fails, a *ValueError* will be raised). The file position is updated to point after the bytes that were written. If the mmap was created with `ACCESS_READ`, then writing to it will raise a *TypeError* exception.

Changed in version 3.5: Writable *bytes-like object* is now accepted.

Changed in version 3.6: The number of bytes written is now returned.

write_byte(*byte*)
Write the integer *byte* into memory at the current position of the file pointer; the file position is advanced by `1`. If the mmap was created with `ACCESS_READ`, then writing to it will raise a *TypeError* exception.

CHAPTER

TWENTY

INTERNET DATA HANDLING

This chapter describes modules which support handling data formats commonly used on the Internet.

20.1 `email` — An email and MIME handling package

Source code: Lib/email/__init__.py

The *email* package is a library for managing email messages. It is specifically *not* designed to do any sending of email messages to SMTP (**RFC 2821**), NNTP, or other servers; those are functions of modules such as *smtplib* and *nntplib*. The *email* package attempts to be as RFC-compliant as possible, supporting **RFC 5233** and **RFC 6532**, as well as such MIME-related RFCs as **RFC 2045**, **RFC 2046**, **RFC 2047**, **RFC 2183**, and **RFC 2231**.

The overall structure of the email package can be divided into three major components, plus a fourth component that controls the behavior of the other components.

The central component of the package is an "object model" that represents email messages. An application interacts with the package primarily through the object model interface defined in the *message* sub-module. The application can use this API to ask questions about an existing email, to construct a new email, or to add or remove email subcomponents that themselves use the same object model interface. That is, following the nature of email messages and their MIME subcomponents, the email object model is a tree structure of objects that all provide the *EmailMessage* API.

The other two major components of the package are the *parser* and the *generator*. The parser takes the serialized version of an email message (a stream of bytes) and converts it into a tree of *EmailMessage* objects. The generator takes an *EmailMessage* and turns it back into a serialized byte stream. (The parser and generator also handle streams of text characters, but this usage is discouraged as it is too easy to end up with messages that are not valid in one way or another.)

The control component is the *policy* module. Every *EmailMessage*, every *generator*, and every *parser* has an associated *policy* object that controls its behavior. Usually an application only needs to specify the policy when an *EmailMessage* is created, either by directly instantiating an *EmailMessage* to create a new email, or by parsing an input stream using a *parser*. But the policy can be changed when the message is serialized using a *generator*. This allows, for example, a generic email message to be parsed from disk, but to serialize it using standard SMTP settings when sending it to an email server.

The email package does its best to hide the details of the various governing RFCs from the application. Conceptually the application should be able to treat the email message as a structured tree of unicode text and binary attachments, without having to worry about how these are represented when serialized. In practice, however, it is often necessary to be aware of at least some of the rules governing MIME messages and their structure, specifically the names and nature of the MIME "content types" and how they identify multipart documents. For the most part this knowledge should only be required for more complex applications, and even then it should only be the high level structure in question, and not the details of how those structures

are represented. Since MIME content types are used widely in modern internet software (not just email), this will be a familiar concept to many programmers.

The following sections describe the functionality of the *email* package. We start with the *message* object model, which is the primary interface an application will use, and follow that with the *parser* and *generator* components. Then we cover the *policy* controls, which completes the treatment of the main components of the library.

The next three sections cover the exceptions the package may raise and the defects (non-compliance with the RFCs) that the *parser* may detect. Then we cover the *headerregistry* and the *contentmanager* subcomponents, which provide tools for doing more detailed manipulation of headers and payloads, respectively. Both of these components contain features relevant to consuming and producing non-trivial messages, but also document their extensibility APIs, which will be of interest to advanced applications.

Following those is a set of examples of using the fundamental parts of the APIs covered in the preceding sections.

The forgoing represent the modern (unicode friendly) API of the email package. The remaining sections, starting with the *Message* class, cover the legacy *compat32* API that deals much more directly with the details of how email messages are represented. The *compat32* API does *not* hide the details of the RFCs from the application, but for applications that need to operate at that level, they can be useful tools. This documentation is also relevant for applications that are still using the *compat32* API for backward compatibility reasons.

Changed in version 3.6: Docs reorganized and rewritten to promote the new *EmailMessage*/*EmailPolicy* API.

Contents of the *email* package documentation:

20.1.1 email.message: Representing an email message

Source code: Lib/email/message.py

New in version 3.6:[1]

The central class in the *email* package is the *EmailMessage* class, imported from the *email.message* module. It is the base class for the *email* object model. *EmailMessage* provides the core functionality for setting and querying header fields, for accessing message bodies, and for creating or modifying structured messages.

An email message consists of *headers* and a *payload* (which is also referred to as the *content*). Headers are **RFC 5322** or **RFC 6532** style field names and values, where the field name and value are separated by a colon. The colon is not part of either the field name or the field value. The payload may be a simple text message, or a binary object, or a structured sequence of sub-messages each with their own set of headers and their own payload. The latter type of payload is indicated by the message having a MIME type such as *multipart/** or *message/rfc822*.

The conceptual model provided by an *EmailMessage* object is that of an ordered dictionary of headers coupled with a *payload* that represents the **RFC 5322** body of the message, which might be a list of sub-`EmailMessage` objects. In addition to the normal dictionary methods for accessing the header names and values, there are methods for accessing specialized information from the headers (for example the MIME content type), for operating on the payload, for generating a serialized version of the message, and for recursively walking over the object tree.

The *EmailMessage* dictionary-like interface is indexed by the header names, which must be ASCII values. The values of the dictionary are strings with some extra methods. Headers are stored and returned in case-preserving form, but field names are matched case-insensitively. Unlike a real dict, there is an ordering to

[1] Originally added in 3.4 as a *provisional module*. Docs for legacy message class moved to *email.message.Message: Representing an email message using the compat32 API*.

the keys, and there can be duplicate keys. Additional methods are provided for working with headers that have duplicate keys.

The *payload* is either a string or bytes object, in the case of simple message objects, or a list of *EmailMessage* objects, for MIME container documents such as *multipart/** and *message/rfc822* message objects.

class email.message.EmailMessage(*policy=default*)

If *policy* is specified use the rules it specifies to update and serialize the representation of the message. If *policy* is not set, use the *default* policy, which follows the rules of the email RFCs except for line endings (instead of the RFC mandated `\r\n`, it uses the Python standard `\n` line endings). For more information see the *policy* documentation.

as_string(*unixfrom=False*, *maxheaderlen=None*, *policy=None*)

Return the entire message flattened as a string. When optional *unixfrom* is true, the envelope header is included in the returned string. *unixfrom* defaults to `False`. For backward compatibility with the base *Message* class *maxheaderlen* is accepted, but defaults to `None`, which means that by default the line length is controlled by the `max_line_length` of the policy. The *policy* argument may be used to override the default policy obtained from the message instance. This can be used to control some of the formatting produced by the method, since the specified *policy* will be passed to the *Generator*.

Flattening the message may trigger changes to the *EmailMessage* if defaults need to be filled in to complete the transformation to a string (for example, MIME boundaries may be generated or modified).

Note that this method is provided as a convenience and may not be the most useful way to serialize messages in your application, especially if you are dealing with multiple messages. See *email.generator.Generator* for a more flexible API for serializing messages. Note also that this method is restricted to producing messages serialized as "7 bit clean" when *utf8* is `False`, which is the default.

Changed in version 3.6: the default behavior when *maxheaderlen* is not specified was changed from defaulting to 0 to defaulting to the value of *max_line_length* from the policy.

__str__()

Equivalent to *as_string(policy=self.policy.clone(utf8=True)*. Allows `str(msg)` to produce a string containing the serialized message in a readable format.

Changed in version 3.4: the method was changed to use `utf8=True`, thus producing an **RFC 6531**-like message representation, instead of being a direct alias for *as_string()*.

as_bytes(*unixfrom=False*, *policy=None*)

Return the entire message flattened as a bytes object. When optional *unixfrom* is true, the envelope header is included in the returned string. *unixfrom* defaults to `False`. The *policy* argument may be used to override the default policy obtained from the message instance. This can be used to control some of the formatting produced by the method, since the specified *policy* will be passed to the *BytesGenerator*.

Flattening the message may trigger changes to the *EmailMessage* if defaults need to be filled in to complete the transformation to a string (for example, MIME boundaries may be generated or modified).

Note that this method is provided as a convenience and may not be the most useful way to serialize messages in your application, especially if you are dealing with multiple messages. See *email.generator.BytesGenerator* for a more flexible API for serializing messages.

__bytes__()

Equivalent to *as_bytes()*. Allows `bytes(msg)` to produce a bytes object containing the serialized message.

is_multipart()
Return `True` if the message's payload is a list of sub-*EmailMessage* objects, otherwise return `False`. When *is_multipart()* returns `False`, the payload should be a string object (which might be a CTE encoded binary payload). Note that *is_multipart()* returning `True` does not necessarily mean that "msg.get_content_maintype() == 'multipart'" will return the `True`. For example, `is_multipart` will return `True` when the *EmailMessage* is of type `message/rfc822`.

set_unixfrom(*unixfrom*)
Set the message's envelope header to *unixfrom*, which should be a string. (See *mboxMessage* for a brief description of this header.)

get_unixfrom()
Return the message's envelope header. Defaults to `None` if the envelope header was never set.

The following methods implement the mapping-like interface for accessing the message's headers. Note that there are some semantic differences between these methods and a normal mapping (i.e. dictionary) interface. For example, in a dictionary there are no duplicate keys, but here there may be duplicate message headers. Also, in dictionaries there is no guaranteed order to the keys returned by *keys()*, but in an *EmailMessage* object, headers are always returned in the order they appeared in the original message, or in which they were added to the message later. Any header deleted and then re-added is always appended to the end of the header list.

These semantic differences are intentional and are biased toward convenience in the most common use cases.

Note that in all cases, any envelope header present in the message is not included in the mapping interface.

__len__()
Return the total number of headers, including duplicates.

__contains__(*name*)
Return true if the message object has a field named *name*. Matching is done without regard to case and *name* does not include the trailing colon. Used for the `in` operator. For example:

```
if 'message-id' in myMessage:
   print('Message-ID:', myMessage['message-id'])
```

__getitem__(*name*)
Return the value of the named header field. *name* does not include the colon field separator. If the header is missing, `None` is returned; a *KeyError* is never raised.

Note that if the named field appears more than once in the message's headers, exactly which of those field values will be returned is undefined. Use the *get_all()* method to get the values of all the extant headers named *name*.

Using the standard (non-`compat32`) policies, the returned value is an instance of a subclass of *email.headerregistry.BaseHeader*.

__setitem__(*name*, *val*)
Add a header to the message with field name *name* and value *val*. The field is appended to the end of the message's existing headers.

Note that this does *not* overwrite or delete any existing header with the same name. If you want to ensure that the new header is the only one present in the message with field name *name*, delete the field first, e.g.:

```
del msg['subject']
msg['subject'] = 'Python roolz!'
```

If the `policy` defines certain headers to be unique (as the standard policies do), this method may raise a *ValueError* when an attempt is made to assign a value to such a header when one already exists. This behavior is intentional for consistency's sake, but do not depend on it as we may choose to make such assignments do an automatic deletion of the existing header in the future.

__delitem__(*name*)
Delete all occurrences of the field with name *name* from the message's headers. No exception is raised if the named field isn't present in the headers.

keys()
Return a list of all the message's header field names.

values()
Return a list of all the message's field values.

items()
Return a list of 2-tuples containing all the message's field headers and values.

get(*name*, *failobj=None*)
Return the value of the named header field. This is identical to *__getitem__()* except that optional *failobj* is returned if the named header is missing (*failobj* defaults to `None`).

Here are some additional useful header related methods:

get_all(*name*, *failobj=None*)
Return a list of all the values for the field named *name*. If there are no such named headers in the message, *failobj* is returned (defaults to `None`).

add_header(*_name*, *_value*, ***_params*)
Extended header setting. This method is similar to *__setitem__()* except that additional header parameters can be provided as keyword arguments. *_name* is the header field to add and *_value* is the *primary* value for the header.

For each item in the keyword argument dictionary *_params*, the key is taken as the parameter name, with underscores converted to dashes (since dashes are illegal in Python identifiers). Normally, the parameter will be added as `key="value"` unless the value is `None`, in which case only the key will be added.

If the value contains non-ASCII characters, the charset and language may be explicitly controlled by specifying the value as a three tuple in the format `(CHARSET, LANGUAGE, VALUE)`, where `CHARSET` is a string naming the charset to be used to encode the value, `LANGUAGE` can usually be set to `None` or the empty string (see **RFC 2231** for other possibilities), and `VALUE` is the string value containing non-ASCII code points. If a three tuple is not passed and the value contains non-ASCII characters, it is automatically encoded in **RFC 2231** format using a `CHARSET` of `utf-8` and a `LANGUAGE` of `None`.

Here is an example:

```
msg.add_header('Content-Disposition', 'attachment', filename='bud.gif')
```

This will add a header that looks like

```
Content-Disposition: attachment; filename="bud.gif"
```

An example of the extended interface with non-ASCII characters:

```
msg.add_header('Content-Disposition', 'attachment',
               filename=('iso-8859-1', '', 'Fußballer.ppt'))
```

replace_header(*_name*, *_value*)
Replace a header. Replace the first header found in the message that matches *_name*, retaining

header order and field name case of the original header. If no matching header is found, raise a *KeyError*.

get_content_type()
Return the message's content type, coerced to lower case of the form *maintype/subtype*. If there is no *Content-Type* header in the message return the value returned by *get_default_type()*. If the *Content-Type* header is invalid, return `text/plain`.

(According to **RFC 2045**, messages always have a default type, *get_content_type()* will always return a value. **RFC 2045** defines a message's default type to be *text/plain* unless it appears inside a *multipart/digest* container, in which case it would be *message/rfc822*. If the *Content-Type* header has an invalid type specification, **RFC 2045** mandates that the default type be *text/plain*.)

get_content_maintype()
Return the message's main content type. This is the *maintype* part of the string returned by *get_content_type()*.

get_content_subtype()
Return the message's sub-content type. This is the *subtype* part of the string returned by *get_content_type()*.

get_default_type()
Return the default content type. Most messages have a default content type of *text/plain*, except for messages that are subparts of *multipart/digest* containers. Such subparts have a default content type of *message/rfc822*.

set_default_type(*ctype*)
Set the default content type. *ctype* should either be *text/plain* or *message/rfc822*, although this is not enforced. The default content type is not stored in the *Content-Type* header, so it only affects the return value of the `get_content_type` methods when no *Content-Type* header is present in the message.

set_param(*param*, *value*, *header='Content-Type'*, *requote=True*, *charset=None*, *language=''*, *replace=False*)
Set a parameter in the *Content-Type* header. If the parameter already exists in the header, replace its value with *value*. When *header* is `Content-Type` (the default) and the header does not yet exist in the message, add it, set its value to *text/plain*, and append the new parameter value. Optional *header* specifies an alternative header to *Content-Type*.

If the value contains non-ASCII characters, the charset and language may be explicitly specified using the optional *charset* and *language* parameters. Optional *language* specifies the **RFC 2231** language, defaulting to the empty string. Both *charset* and *language* should be strings. The default is to use the `utf8` *charset* and `None` for the *language*.

If *replace* is `False` (the default) the header is moved to the end of the list of headers. If *replace* is `True`, the header will be updated in place.

Use of the *requote* parameter with *EmailMessage* objects is deprecated.

Note that existing parameter values of headers may be accessed through the `params` attribute of the header value (for example, `msg['Content-Type'].params['charset']`.

Changed in version 3.4: `replace` keyword was added.

del_param(*param*, *header='content-type'*, *requote=True*)
Remove the given parameter completely from the *Content-Type* header. The header will be rewritten in place without the parameter or its value. Optional *header* specifies an alternative to *Content-Type*.

Use of the *requote* parameter with *EmailMessage* objects is deprecated.

get_filename(*failobj=None*)
Return the value of the `filename` parameter of the *Content-Disposition* header of the message. If the header does not have a `filename` parameter, this method falls back to looking for the `name` parameter on the *Content-Type* header. If neither is found, or the header is missing, then *failobj* is returned. The returned string will always be unquoted as per *email.utils.unquote()*.

get_boundary(*failobj=None*)
Return the value of the `boundary` parameter of the *Content-Type* header of the message, or *failobj* if either the header is missing, or has no `boundary` parameter. The returned string will always be unquoted as per *email.utils.unquote()*.

set_boundary(*boundary*)
Set the `boundary` parameter of the *Content-Type* header to *boundary*. *set_boundary()* will always quote *boundary* if necessary. A *HeaderParseError* is raised if the message object has no *Content-Type* header.

Note that using this method is subtly different from deleting the old *Content-Type* header and adding a new one with the new boundary via *add_header()*, because *set_boundary()* preserves the order of the *Content-Type* header in the list of headers.

get_content_charset(*failobj=None*)
Return the `charset` parameter of the *Content-Type* header, coerced to lower case. If there is no *Content-Type* header, or if that header has no `charset` parameter, *failobj* is returned.

get_charsets(*failobj=None*)
Return a list containing the character set names in the message. If the message is a *multipart*, then the list will contain one element for each subpart in the payload, otherwise, it will be a list of length 1.

Each item in the list will be a string which is the value of the `charset` parameter in the *Content-Type* header for the represented subpart. If the subpart has no *Content-Type* header, no `charset` parameter, or is not of the *text* main MIME type, then that item in the returned list will be *failobj*.

is_attachment()
Return `True` if there is a *Content-Disposition* header and its (case insensitive) value is `attachment`, `False` otherwise.

Changed in version 3.4.2: is_attachment is now a method instead of a property, for consistency with *is_multipart()*.

get_content_disposition()
Return the lowercased value (without parameters) of the message's *Content-Disposition* header if it has one, or `None`. The possible values for this method are *inline*, *attachment* or `None` if the message follows **RFC 2183**.

New in version 3.5.

The following methods relate to interrogating and manipulating the content (payload) of the message.

walk()
The *walk()* method is an all-purpose generator which can be used to iterate over all the parts and subparts of a message object tree, in depth-first traversal order. You will typically use *walk()* as the iterator in a `for` loop; each iteration returns the next subpart.

Here's an example that prints the MIME type of every part of a multipart message structure:

```
>>> for part in msg.walk():
...     print(part.get_content_type())
multipart/report
```

(continues on next page)

(continued from previous page)

```
text/plain
message/delivery-status
text/plain
text/plain
message/rfc822
text/plain
```

`walk` iterates over the subparts of any part where *is_multipart()* returns `True`, even though `msg.get_content_maintype() == 'multipart'` may return `False`. We can see this in our example by making use of the `_structure` debug helper function:

```
>>> for part in msg.walk():
...     print(part.get_content_maintype() == 'multipart',
...           part.is_multipart())
True True
False False
False True
False False
False False
False True
False False
>>> _structure(msg)
multipart/report
    text/plain
    message/delivery-status
        text/plain
        text/plain
    message/rfc822
        text/plain
```

Here the `message` parts are not `multiparts`, but they do contain subparts. `is_multipart()` returns `True` and `walk` descends into the subparts.

`get_body`(*preferencelist=('related', 'html', 'plain')*)
Return the MIME part that is the best candidate to be the "body" of the message.

preferencelist must be a sequence of strings from the set `related`, `html`, and `plain`, and indicates the order of preference for the content type of the part returned.

Start looking for candidate matches with the object on which the `get_body` method is called.

If `related` is not included in *preferencelist*, consider the root part (or subpart of the root part) of any related encountered as a candidate if the (sub-)part matches a preference.

When encountering a `multipart/related`, check the `start` parameter and if a part with a matching *Content-ID* is found, consider only it when looking for candidate matches. Otherwise consider only the first (default root) part of the `multipart/related`.

If a part has a *Content-Disposition* header, only consider the part a candidate match if the value of the header is `inline`.

If none of the candidates matches any of the preferences in *preferencelist*, return `None`.

Notes: (1) For most applications the only *preferencelist* combinations that really make sense are `('plain',)`, `('html', 'plain')`, and the default `('related', 'html', 'plain')`. (2) Because matching starts with the object on which `get_body` is called, calling `get_body` on a `multipart/related` will return the object itself unless *preferencelist* has a non-default value. (3) Messages (or message parts) that do not specify a *Content-Type* or whose *Content-Type* header is invalid will be treated as if they are of type `text/plain`, which may occasionally cause `get_body` to return unexpected results.

iter_attachments()
Return an iterator over all of the immediate sub-parts of the message that are not candidate "body" parts. That is, skip the first occurrence of each of `text/plain`, `text/html`, `multipart/related`, or `multipart/alternative` (unless they are explicitly marked as attachments via *Content-Disposition: attachment*), and return all remaining parts. When applied directly to a `multipart/related`, return an iterator over the all the related parts except the root part (ie: the part pointed to by the `start` parameter, or the first part if there is no `start` parameter or the `start` parameter doesn't match the *Content-ID* of any of the parts). When applied directly to a `multipart/alternative` or a non-`multipart`, return an empty iterator.

iter_parts()
Return an iterator over all of the immediate sub-parts of the message, which will be empty for a non-`multipart`. (See also *walk()*.)

get_content(**args*, *content_manager=None*, ***kw*)
Call the *get_content()* method of the *content_manager*, passing self as the message object, and passing along any other arguments or keywords as additional arguments. If *content_manager* is not specified, use the `content_manager` specified by the current *policy*.

set_content(**args*, *content_manager=None*, ***kw*)
Call the *set_content()* method of the *content_manager*, passing self as the message object, and passing along any other arguments or keywords as additional arguments. If *content_manager* is not specified, use the `content_manager` specified by the current *policy*.

make_related(*boundary=None*)
Convert a non-`multipart` message into a `multipart/related` message, moving any existing *Content-* headers and payload into a (new) first part of the `multipart`. If *boundary* is specified, use it as the boundary string in the multipart, otherwise leave the boundary to be automatically created when it is needed (for example, when the message is serialized).

make_alternative(*boundary=None*)
Convert a non-`multipart` or a `multipart/related` into a `multipart/alternative`, moving any existing *Content-* headers and payload into a (new) first part of the `multipart`. If *boundary* is specified, use it as the boundary string in the multipart, otherwise leave the boundary to be automatically created when it is needed (for example, when the message is serialized).

make_mixed(*boundary=None*)
Convert a non-`multipart`, a `multipart/related`, or a `multipart-alternative` into a `multipart/mixed`, moving any existing *Content-* headers and payload into a (new) first part of the `multipart`. If *boundary* is specified, use it as the boundary string in the multipart, otherwise leave the boundary to be automatically created when it is needed (for example, when the message is serialized).

add_related(**args*, *content_manager=None*, ***kw*)
If the message is a `multipart/related`, create a new message object, pass all of the arguments to its *set_content()* method, and *attach()* it to the `multipart`. If the message is a non-`multipart`, call *make_related()* and then proceed as above. If the message is any other type of `multipart`, raise a *TypeError*. If *content_manager* is not specified, use the `content_manager` specified by the current *policy*. If the added part has no *Content-Disposition* header, add one with the value `inline`.

add_alternative(**args*, *content_manager=None*, ***kw*)
If the message is a `multipart/alternative`, create a new message object, pass all of the arguments to its *set_content()* method, and *attach()* it to the `multipart`. If the message is a non-`multipart` or `multipart/related`, call *make_alternative()* and then proceed as above. If the message is any other type of `multipart`, raise a *TypeError*. If *content_manager* is not specified, use the `content_manager` specified by the current *policy*.

add_attachment(**args*, *content_manager=None*, ***kw*)

If the message is a `multipart/mixed`, create a new message object, pass all of the arguments to its *set_content()* method, and *attach()* it to the `multipart`. If the message is a non-`multipart`, `multipart/related`, or `multipart/alternative`, call *make_mixed()* and then proceed as above. If *content_manager* is not specified, use the `content_manager` specified by the current *policy*. If the added part has no *Content-Disposition* header, add one with the value `attachment`. This method can be used both for explicit attachments (*Content-Disposition: attachment* and `inline` attachments (*Content-Disposition: inline*), by passing appropriate options to the `content_manager`.

`clear()`
Remove the payload and all of the headers.

`clear_content()`
Remove the payload and all of the `Content-` headers, leaving all other headers intact and in their original order.

EmailMessage objects have the following instance attributes:

`preamble`
The format of a MIME document allows for some text between the blank line following the headers, and the first multipart boundary string. Normally, this text is never visible in a MIME-aware mail reader because it falls outside the standard MIME armor. However, when viewing the raw text of the message, or when viewing the message in a non-MIME aware reader, this text can become visible.

The *preamble* attribute contains this leading extra-armor text for MIME documents. When the *Parser* discovers some text after the headers but before the first boundary string, it assigns this text to the message's *preamble* attribute. When the *Generator* is writing out the plain text representation of a MIME message, and it finds the message has a *preamble* attribute, it will write this text in the area between the headers and the first boundary. See *email.parser* and *email.generator* for details.

Note that if the message object has no preamble, the *preamble* attribute will be `None`.

`epilogue`
The *epilogue* attribute acts the same way as the *preamble* attribute, except that it contains text that appears between the last boundary and the end of the message. As with the *preamble*, if there is no epilog text this attribute will be `None`.

`defects`
The *defects* attribute contains a list of all the problems found when parsing this message. See *email.errors* for a detailed description of the possible parsing defects.

`class email.message.MIMEPart(`*policy=default*`)`
This class represents a subpart of a MIME message. It is identical to *EmailMessage*, except that no *MIME-Version* headers are added when *set_content()* is called, since sub-parts do not need their own *MIME-Version* headers.

20.1.2 `email.parser`: Parsing email messages

Source code: Lib/email/parser.py

Message object structures can be created in one of two ways: they can be created from whole cloth by creating an *EmailMessage* object, adding headers using the dictionary interface, and adding payload(s) using *set_content()* and related methods, or they can be created by parsing a serialized representation of the email message.

The *email* package provides a standard parser that understands most email document structures, including MIME documents. You can pass the parser a bytes, string or file object, and the parser will return to you the root *EmailMessage* instance of the object structure. For simple, non-MIME messages the payload of this root object will likely be a string containing the text of the message. For MIME messages, the root object will return `True` from its *is_multipart()* method, and the subparts can be accessed via the payload manipulation methods, such as *get_body()*, *iter_parts()*, and *walk()*.

There are actually two parser interfaces available for use, the *Parser* API and the incremental *FeedParser* API. The *Parser* API is most useful if you have the entire text of the message in memory, or if the entire message lives in a file on the file system. *FeedParser* is more appropriate when you are reading the message from a stream which might block waiting for more input (such as reading an email message from a socket). The *FeedParser* can consume and parse the message incrementally, and only returns the root object when you close the parser.

Note that the parser can be extended in limited ways, and of course you can implement your own parser completely from scratch. All of the logic that connects the *email* package's bundled parser and the *EmailMessage* class is embodied in the `policy` class, so a custom parser can create message object trees any way it finds necessary by implementing custom versions of the appropriate `policy` methods.

FeedParser API

The *BytesFeedParser*, imported from the `email.feedparser` module, provides an API that is conducive to incremental parsing of email messages, such as would be necessary when reading the text of an email message from a source that can block (such as a socket). The *BytesFeedParser* can of course be used to parse an email message fully contained in a *bytes-like object*, string, or file, but the *BytesParser* API may be more convenient for such use cases. The semantics and results of the two parser APIs are identical.

The *BytesFeedParser*'s API is simple; you create an instance, feed it a bunch of bytes until there's no more to feed it, then close the parser to retrieve the root message object. The *BytesFeedParser* is extremely accurate when parsing standards-compliant messages, and it does a very good job of parsing non-compliant messages, providing information about how a message was deemed broken. It will populate a message object's *defects* attribute with a list of any problems it found in a message. See the *email.errors* module for the list of defects that it can find.

Here is the API for the *BytesFeedParser*:

class email.parser.BytesFeedParser(*_factory=None*, ***, *policy=policy.compat32*)

Create a *BytesFeedParser* instance. Optional *_factory* is a no-argument callable; if not specified use the *message_factory* from the *policy*. Call *_factory* whenever a new message object is needed.

If *policy* is specified use the rules it specifies to update the representation of the message. If *policy* is not set, use the *compat32* policy, which maintains backward compatibility with the Python 3.2 version of the email package and provides *Message* as the default factory. All other policies provide *EmailMessage* as the default *_factory*. For more information on what else *policy* controls, see the *policy* documentation.

Note: **The policy keyword should always be specified**; The default will change to *email.policy.default* in a future version of Python.

New in version 3.2.

Changed in version 3.3: Added the *policy* keyword.

Changed in version 3.6: *_factory* defaults to the policy `message_factory`.

feed(*data*)

Feed the parser some more data. *data* should be a *bytes-like object* containing one or more lines. The lines can be partial and the parser will stitch such partial lines together properly. The lines can have any of the three common line endings: carriage return, newline, or carriage return and newline (they can even be mixed).

`close()`
Complete the parsing of all previously fed data and return the root message object. It is undefined what happens if *feed()* is called after this method has been called.

`class email.parser.FeedParser(_factory=None, *, policy=policy.compat32)`
Works like *BytesFeedParser* except that the input to the *feed()* method must be a string. This is of limited utility, since the only way for such a message to be valid is for it to contain only ASCII text or, if `utf8` is `True`, no binary attachments.

Changed in version 3.3: Added the *policy* keyword.

Parser API

The *BytesParser* class, imported from the *email.parser* module, provides an API that can be used to parse a message when the complete contents of the message are available in a *bytes-like object* or file. The *email.parser* module also provides *Parser* for parsing strings, and header-only parsers, *BytesHeaderParser* and *HeaderParser*, which can be used if you're only interested in the headers of the message. *BytesHeaderParser* and *HeaderParser* can be much faster in these situations, since they do not attempt to parse the message body, instead setting the payload to the raw body.

`class email.parser.BytesParser(_class=None, *, policy=policy.compat32)`
Create a *BytesParser* instance. The *_class* and *policy* arguments have the same meaning and semantics as the *_factory* and *policy* arguments of *BytesFeedParser*.

Note: **The policy keyword should always be specified**; The default will change to *email.policy.default* in a future version of Python.

Changed in version 3.3: Removed the *strict* argument that was deprecated in 2.4. Added the *policy* keyword.

Changed in version 3.6: *_class* defaults to the policy `message_factory`.

`parse(fp, headersonly=False)`
Read all the data from the binary file-like object *fp*, parse the resulting bytes, and return the message object. *fp* must support both the *readline()* and the `read()` methods.

The bytes contained in *fp* must be formatted as a block of **RFC 5322** (or, if `utf8` is `True`, **RFC 6532**) style headers and header continuation lines, optionally preceded by an envelope header. The header block is terminated either by the end of the data or by a blank line. Following the header block is the body of the message (which may contain MIME-encoded subparts, including subparts with a *Content-Transfer-Encoding* of `8bit`.

Optional *headersonly* is a flag specifying whether to stop parsing after reading the headers or not. The default is `False`, meaning it parses the entire contents of the file.

`parsebytes(bytes, headersonly=False)`
Similar to the *parse()* method, except it takes a *bytes-like object* instead of a file-like object. Calling this method on a *bytes-like object* is equivalent to wrapping *bytes* in a *BytesIO* instance first and calling *parse()*.

Optional *headersonly* is as with the *parse()* method.

New in version 3.2.

`class email.parser.BytesHeaderParser(_class=None, *, policy=policy.compat32)`
Exactly like *BytesParser*, except that *headersonly* defaults to `True`.

New in version 3.3.

`class email.parser.Parser(_class=None, *, policy=policy.compat32)`
This class is parallel to *BytesParser*, but handles string input.

Changed in version 3.3: Removed the *strict* argument. Added the *policy* keyword.

Changed in version 3.6: *_class* defaults to the policy `message_factory`.

parse(*fp*, *headersonly=False*)
Read all the data from the text-mode file-like object *fp*, parse the resulting text, and return the root message object. *fp* must support both the *readline()* and the *read()* methods on file-like objects.

Other than the text mode requirement, this method operates like *BytesParser.parse()*.

parsestr(*text*, *headersonly=False*)
Similar to the *parse()* method, except it takes a string object instead of a file-like object. Calling this method on a string is equivalent to wrapping *text* in a *StringIO* instance first and calling *parse()*.

Optional *headersonly* is as with the *parse()* method.

class email.parser.HeaderParser(*_class=None*, ***, *policy=policy.compat32*)
Exactly like *Parser*, except that *headersonly* defaults to `True`.

Since creating a message object structure from a string or a file object is such a common task, four functions are provided as a convenience. They are available in the top-level *email* package namespace.

email.message_from_bytes(*s*, *_class=None*, ***, *policy=policy.compat32*)
Return a message object structure from a *bytes-like object*. This is equivalent to `BytesParser().parsebytes(s)`. Optional *_class* and *strict* are interpreted as with the *BytesParser* class constructor.

New in version 3.2.

Changed in version 3.3: Removed the *strict* argument. Added the *policy* keyword.

message_from_binary_file(fp, _class=None, *, policy=policy.compat32)
Return a message object structure tree from an open binary *file object*. This is equivalent to `BytesParser().parse(fp)`. *_class* and *policy* are interpreted as with the *BytesParser* class constructor.

New in version 3.2.

Changed in version 3.3: Removed the *strict* argument. Added the *policy* keyword.

email.message_from_string(*s*, *_class=None*, ***, *policy=policy.compat32*)
Return a message object structure from a string. This is equivalent to `Parser().parsestr(s)`. *_class* and *policy* are interpreted as with the *Parser* class constructor.

Changed in version 3.3: Removed the *strict* argument. Added the *policy* keyword.

email.message_from_file(*fp*, *_class=None*, ***, *policy=policy.compat32*)
Return a message object structure tree from an open *file object*. This is equivalent to `Parser().parse(fp)`. *_class* and *policy* are interpreted as with the *Parser* class constructor.

Changed in version 3.3: Removed the *strict* argument. Added the *policy* keyword.

Changed in version 3.6: *_class* defaults to the policy `message_factory`.

Here's an example of how you might use *message_from_bytes()* at an interactive Python prompt:

```
>>> import email
>>> msg = email.message_from_bytes(myBytes)
```

Additional notes

Here are some notes on the parsing semantics:

- Most non-*multipart* type messages are parsed as a single message object with a string payload. These objects will return `False` for *is_multipart()*, and *iter_parts()* will yield an empty list.
- All *multipart* type messages will be parsed as a container message object with a list of sub-message objects for their payload. The outer container message will return `True` for *is_multipart()*, and *iter_parts()* will yield a list of subparts.
- Most messages with a content type of *message/** (such as *message/delivery-status* and *message/rfc822*) will also be parsed as container object containing a list payload of length 1. Their *is_multipart()* method will return `True`. The single element yielded by *iter_parts()* will be a sub-message object.
- Some non-standards-compliant messages may not be internally consistent about their *multipart*-edness. Such messages may have a *Content-Type* header of type *multipart*, but their *is_multipart()* method may return `False`. If such messages were parsed with the *FeedParser*, they will have an instance of the `MultipartInvariantViolationDefect` class in their *defects* attribute list. See *email.errors* for details.

20.1.3 `email.generator`: Generating MIME documents

Source code: Lib/email/generator.py

One of the most common tasks is to generate the flat (serialized) version of the email message represented by a message object structure. You will need to do this if you want to send your message via *smtplib.SMTP.sendmail()* or the *nntplib* module, or print the message on the console. Taking a message object structure and producing a serialized representation is the job of the generator classes.

As with the *email.parser* module, you aren't limited to the functionality of the bundled generator; you could write one from scratch yourself. However the bundled generator knows how to generate most email in a standards-compliant way, should handle MIME and non-MIME email messages just fine, and is designed so that the bytes-oriented parsing and generation operations are inverses, assuming the same non-transforming *policy* is used for both. That is, parsing the serialized byte stream via the *BytesParser* class and then regenerating the serialized byte stream using *BytesGenerator* should produce output identical to the input[1]. (On the other hand, using the generator on an *EmailMessage* constructed by program may result in changes to the *EmailMessage* object as defaults are filled in.)

The *Generator* class can be used to flatten a message into a text (as opposed to binary) serialized representation, but since Unicode cannot represent binary data directly, the message is of necessity transformed into something that contains only ASCII characters, using the standard email RFC Content Transfer Encoding techniques for encoding email messages for transport over channels that are not "8 bit clean".

`class email.generator.BytesGenerator(`*outfp*, *mangle_from_=None*, *maxheaderlen=None*, ***, *policy=None*`)`

Return a *BytesGenerator* object that will write any message provided to the *flatten()* method, or any surrogateescape encoded text provided to the *write()* method, to the *file-like object* *outfp*. *outfp* must support a `write` method that accepts binary data.

If optional *mangle_from_* is `True`, put a `>` character in front of any line in the body that starts with the exact string `"From "`, that is `From` followed by a space at the beginning of a line. *mangle_from_* defaults to the value of the *mangle_from_* setting of the *policy* (which is `True` for the *compat32* policy and `False` for all others). *mangle_from_* is intended for use when messages are stored in unix mbox format (see *mailbox* and WHY THE CONTENT-LENGTH FORMAT IS BAD).

[1] This statement assumes that you use the appropriate setting for `unixfrom`, and that there are no `policy` settings calling for automatic adjustments (for example, `refold_source` must be `none`, which is *not* the default). It is also not 100% true, since if the message does not conform to the RFC standards occasionally information about the exact original text is lost during parsing error recovery. It is a goal to fix these latter edge cases when possible.

If *maxheaderlen* is not `None`, refold any header lines that are longer than *maxheaderlen*, or if `0`, do not rewrap any headers. If *manheaderlen* is `None` (the default), wrap headers and other message lines according to the *policy* settings.

If *policy* is specified, use that policy to control message generation. If *policy* is `None` (the default), use the policy associated with the *Message* or *EmailMessage* object passed to `flatten` to control the message generation. See *email.policy* for details on what *policy* controls.

New in version 3.2.

Changed in version 3.3: Added the *policy* keyword.

Changed in version 3.6: The default behavior of the *mangle_from_* and *maxheaderlen* parameters is to follow the policy.

`flatten`(*msg*, *unixfrom=False*, *linesep=None*)

Print the textual representation of the message object structure rooted at *msg* to the output file specified when the *BytesGenerator* instance was created.

If the *policy* option *cte_type* is `8bit` (the default), copy any headers in the original parsed message that have not been modified to the output with any bytes with the high bit set reproduced as in the original, and preserve the non-ASCII *Content-Transfer-Encoding* of any body parts that have them. If `cte_type` is `7bit`, convert the bytes with the high bit set as needed using an ASCII-compatible *Content-Transfer-Encoding*. That is, transform parts with non-ASCII *Content-Transfer-Encoding* (*Content-Transfer-Encoding: 8bit*) to an ASCII compatible *Content-Transfer-Encoding*, and encode RFC-invalid non-ASCII bytes in headers using the MIME `unknown-8bit` character set, thus rendering them RFC-compliant.

If *unixfrom* is `True`, print the envelope header delimiter used by the Unix mailbox format (see *mailbox*) before the first of the **RFC 5322** headers of the root message object. If the root object has no envelope header, craft a standard one. The default is `False`. Note that for subparts, no envelope header is ever printed.

If *linesep* is not `None`, use it as the separator character between all the lines of the flattened message. If *linesep* is `None` (the default), use the value specified in the *policy*.

`clone`(*fp*)

Return an independent clone of this *BytesGenerator* instance with the exact same option settings, and *fp* as the new *outfp*.

`write`(*s*)

Encode *s* using the `ASCII` codec and the `surrogateescape` error handler, and pass it to the *write* method of the *outfp* passed to the *BytesGenerator*'s constructor.

As a convenience, *EmailMessage* provides the methods *as_bytes()* and `bytes(aMessage)` (a.k.a. *__bytes__()*), which simplify the generation of a serialized binary representation of a message object. For more detail, see *email.message*.

Because strings cannot represent binary data, the *Generator* class must convert any binary data in any message it flattens to an ASCII compatible format, by converting them to an ASCII compatible *Content-Transfer_Encoding*. Using the terminology of the email RFCs, you can think of this as *Generator* serializing to an I/O stream that is not "8 bit clean". In other words, most applications will want to be using *BytesGenerator*, and not *Generator*.

`class email.generator.Generator`(*outfp*, *mangle_from_=None*, *maxheaderlen=None*, ***, *policy=None*)

Return a *Generator* object that will write any message provided to the *flatten()* method, or any text provided to the *write()* method, to the *file-like object* *outfp*. *outfp* must support a `write` method that accepts string data.

If optional *mangle_from_* is `True`, put a `>` character in front of any line in the body that starts with the exact string `"From "`, that is `From` followed by a space at the beginning of a line. *mangle_from_*

defaults to the value of the *mangle_from_* setting of the *policy* (which is `True` for the *compat32* policy and `False` for all others). *mangle_from_* is intended for use when messages are stored in unix mbox format (see *mailbox* and WHY THE CONTENT-LENGTH FORMAT IS BAD).

If *maxheaderlen* is not `None`, refold any header lines that are longer than *maxheaderlen*, or if `0`, do not rewrap any headers. If *manheaderlen* is `None` (the default), wrap headers and other message lines according to the *policy* settings.

If *policy* is specified, use that policy to control message generation. If *policy* is `None` (the default), use the policy associated with the *Message* or *EmailMessage* object passed to `flatten` to control the message generation. See *email.policy* for details on what *policy* controls.

Changed in version 3.3: Added the *policy* keyword.

Changed in version 3.6: The default behavior of the *mangle_from_* and *maxheaderlen* parameters is to follow the policy.

`flatten`(*msg*, *unixfrom=False*, *linesep=None*)

Print the textual representation of the message object structure rooted at *msg* to the output file specified when the *Generator* instance was created.

If the *policy* option *cte_type* is `8bit`, generate the message as if the option were set to `7bit`. (This is required because strings cannot represent non-ASCII bytes.) Convert any bytes with the high bit set as needed using an ASCII-compatible *Content-Transfer-Encoding*. That is, transform parts with non-ASCII *Cotnent-Transfer-Encoding* (*Content-Transfer-Encoding: 8bit*) to an ASCII compatible *Content-Transfer-Encoding*, and encode RFC-invalid non-ASCII bytes in headers using the MIME `unknown-8bit` character set, thus rendering them RFC-compliant.

If *unixfrom* is `True`, print the envelope header delimiter used by the Unix mailbox format (see *mailbox*) before the first of the **RFC 5322** headers of the root message object. If the root object has no envelope header, craft a standard one. The default is `False`. Note that for subparts, no envelope header is ever printed.

If *linesep* is not `None`, use it as the separator character between all the lines of the flattened message. If *linesep* is `None` (the default), use the value specified in the *policy*.

Changed in version 3.2: Added support for re-encoding `8bit` message bodies, and the *linesep* argument.

`clone`(*fp*)

Return an independent clone of this *Generator* instance with the exact same options, and *fp* as the new *outfp*.

`write`(*s*)

Write *s* to the *write* method of the *outfp* passed to the *Generator*'s constructor. This provides just enough file-like API for *Generator* instances to be used in the *print()* function.

As a convenience, *EmailMessage* provides the methods *as_string()* and `str(aMessage)` (a.k.a. *__str__()*), which simplify the generation of a formatted string representation of a message object. For more detail, see *email.message*.

The *email.generator* module also provides a derived class, *DecodedGenerator*, which is like the *Generator* base class, except that non-*text* parts are not serialized, but are instead represented in the output stream by a string derived from a template filled in with information about the part.

`class email.generator.DecodedGenerator`(*outfp*, *mangle_from_=None*, *maxheaderlen=None*, *fmt=None*, ***, *policy=None*)

Act like *Generator*, except that for any subpart of the message passed to *Generator.flatten()*, if the subpart is of main type *text*, print the decoded payload of the subpart, and if the main type is not *text*, instead of printing it fill in the string *fmt* using information from the part and print the resulting filled-in string.

To fill in *fmt*, execute `fmt % part_info`, where `part_info` is a dictionary composed of the following keys and values:

- `type` – Full MIME type of the non-*text* part
- `maintype` – Main MIME type of the non-*text* part
- `subtype` – Sub-MIME type of the non-*text* part
- `filename` – Filename of the non-*text* part
- `description` – Description associated with the non-*text* part
- `encoding` – Content transfer encoding of the non-*text* part

If *fmt* is `None`, use the following default *fmt*:

"[Non-text (%(type)s) part of message omitted, filename %(filename)s]"

Optional *_mangle_from_* and *maxheaderlen* are as with the *Generator* base class.

20.1.4 `email.policy`: Policy Objects

New in version 3.3.

Source code: Lib/email/policy.py

The *email* package's prime focus is the handling of email messages as described by the various email and MIME RFCs. However, the general format of email messages (a block of header fields each consisting of a name followed by a colon followed by a value, the whole block followed by a blank line and an arbitrary 'body'), is a format that has found utility outside of the realm of email. Some of these uses conform fairly closely to the main email RFCs, some do not. Even when working with email, there are times when it is desirable to break strict compliance with the RFCs, such as generating emails that interoperate with email servers that do not themselves follow the standards, or that implement extensions you want to use in ways that violate the standards.

Policy objects give the email package the flexibility to handle all these disparate use cases.

A *Policy* object encapsulates a set of attributes and methods that control the behavior of various components of the email package during use. *Policy* instances can be passed to various classes and methods in the email package to alter the default behavior. The settable values and their defaults are described below.

There is a default policy used by all classes in the email package. For all of the *parser* classes and the related convenience functions, and for the *Message* class, this is the *Compat32* policy, via its corresponding pre-defined instance *compat32*. This policy provides for complete backward compatibility (in some cases, including bug compatibility) with the pre-Python3.3 version of the email package.

This default value for the *policy* keyword to *EmailMessage* is the *EmailPolicy* policy, via its pre-defined instance *default*.

When a *Message* or *EmailMessage* object is created, it acquires a policy. If the message is created by a *parser*, a policy passed to the parser will be the policy used by the message it creates. If the message is created by the program, then the policy can be specified when it is created. When a message is passed to a *generator*, the generator uses the policy from the message by default, but you can also pass a specific policy to the generator that will override the one stored on the message object.

The default value for the *policy* keyword for the *email.parser* classes and the parser convenience functions **will be changing** in a future version of Python. Therefore you should **always specify explicitly which policy you want to use** when calling any of the classes and functions described in the *parser* module.

The first part of this documentation covers the features of *Policy*, an *abstract base class* that defines the features that are common to all policy objects, including *compat32*. This includes certain hook methods

that are called internally by the email package, which a custom policy could override to obtain different behavior. The second part describes the concrete classes *EmailPolicy* and *Compat32*, which implement the hooks that provide the standard behavior and the backward compatible behavior and features, respectively.

Policy instances are immutable, but they can be cloned, accepting the same keyword arguments as the class constructor and returning a new *Policy* instance that is a copy of the original but with the specified attributes values changed.

As an example, the following code could be used to read an email message from a file on disk and pass it to the system `sendmail` program on a Unix system:

```
>>> from email import message_from_binary_file
>>> from email.generator import BytesGenerator
>>> from email import policy
>>> from subprocess import Popen, PIPE
>>> with open('mymsg.txt', 'rb') as f:
...     msg = message_from_binary_file(f, policy=policy.default)
>>> p = Popen(['sendmail', msg['To'].addresses[0]], stdin=PIPE)
>>> g = BytesGenerator(p.stdin, policy=msg.policy.clone(linesep='\r\n'))
>>> g.flatten(msg)
>>> p.stdin.close()
>>> rc = p.wait()
```

Here we are telling *BytesGenerator* to use the RFC correct line separator characters when creating the binary string to feed into `sendmail's stdin`, where the default policy would use `\n` line separators.

Some email package methods accept a *policy* keyword argument, allowing the policy to be overridden for that method. For example, the following code uses the *as_bytes()* method of the *msg* object from the previous example and writes the message to a file using the native line separators for the platform on which it is running:

```
>>> import os
>>> with open('converted.txt', 'wb') as f:
...     f.write(msg.as_bytes(policy=msg.policy.clone(linesep=os.linesep)))
17
```

Policy objects can also be combined using the addition operator, producing a policy object whose settings are a combination of the non-default values of the summed objects:

```
>>> compat_SMTP = policy.compat32.clone(linesep='\r\n')
>>> compat_strict = policy.compat32.clone(raise_on_defect=True)
>>> compat_strict_SMTP = compat_SMTP + compat_strict
```

This operation is not commutative; that is, the order in which the objects are added matters. To illustrate:

```
>>> policy100 = policy.compat32.clone(max_line_length=100)
>>> policy80 = policy.compat32.clone(max_line_length=80)
>>> apolicy = policy100 + policy80
>>> apolicy.max_line_length
80
>>> apolicy = policy80 + policy100
>>> apolicy.max_line_length
100
```

class email.policy.**Policy**(***kw*)

This is the *abstract base class* for all policy classes. It provides default implementations for a couple of trivial methods, as well as the implementation of the immutability property, the *clone()* method, and the constructor semantics.

The constructor of a policy class can be passed various keyword arguments. The arguments that may be specified are any non-method properties on this class, plus any additional non-method properties on the concrete class. A value specified in the constructor will override the default value for the corresponding attribute.

This class defines the following properties, and thus values for the following may be passed in the constructor of any policy class:

max_line_length
The maximum length of any line in the serialized output, not counting the end of line character(s). Default is 78, per **RFC 5322**. A value of `0` or *None* indicates that no line wrapping should be done at all.

linesep
The string to be used to terminate lines in serialized output. The default is `\n` because that's the internal end-of-line discipline used by Python, though `\r\n` is required by the RFCs.

cte_type
Controls the type of Content Transfer Encodings that may be or are required to be used. The possible values are:

`7bit`	all data must be "7 bit clean" (ASCII-only). This means that where necessary data will be encoded using either quoted-printable or base64 encoding.
`8bit`	data is not constrained to be 7 bit clean. Data in headers is still required to be ASCII-only and so will be encoded (see *fold_binary()* and *utf8* below for exceptions), but body parts may use the `8bit` CTE.

A `cte_type` value of `8bit` only works with `BytesGenerator`, not `Generator`, because strings cannot contain binary data. If a `Generator` is operating under a policy that specifies `cte_type=8bit`, it will act as if `cte_type` is `7bit`.

raise_on_defect
If *True*, any defects encountered will be raised as errors. If *False* (the default), defects will be passed to the *register_defect()* method.

mangle_from_
If *True*, lines starting with *"From "* in the body are escaped by putting a `>` in front of them. This parameter is used when the message is being serialized by a generator. Default: *False*.

New in version 3.5: The *mangle_from_* parameter.

message_factory
A factory function for constructing a new empty message object. Used by the parser when building messages. Defaults to `None`, in which case *Message* is used.

New in version 3.6.

The following *Policy* method is intended to be called by code using the email library to create policy instances with custom settings:

clone(***kw*)
Return a new *Policy* instance whose attributes have the same values as the current instance, except where those attributes are given new values by the keyword arguments.

The remaining *Policy* methods are called by the email package code, and are not intended to be called by an application using the email package. A custom policy must implement all of these methods.

handle_defect(*obj*, *defect*)
Handle a *defect* found on *obj*. When the email package calls this method, *defect* will always be a subclass of `Defect`.

The default implementation checks the *raise_on_defect* flag. If it is `True`, *defect* is raised as an exception. If it is `False` (the default), *obj* and *defect* are passed to *register_defect()*.

register_defect(*obj*, *defect*)
Register a *defect* on *obj*. In the email package, *defect* will always be a subclass of `Defect`.

The default implementation calls the `append` method of the `defects` attribute of *obj*. When the email package calls *handle_defect*, *obj* will normally have a `defects` attribute that has an `append` method. Custom object types used with the email package (for example, custom `Message` objects) should also provide such an attribute, otherwise defects in parsed messages will raise unexpected errors.

header_max_count(*name*)
Return the maximum allowed number of headers named *name*.

Called when a header is added to an *EmailMessage* or *Message* object. If the returned value is not `0` or `None`, and there are already a number of headers with the name *name* greater than or equal to the value returned, a *ValueError* is raised.

Because the default behavior of `Message.__setitem__` is to append the value to the list of headers, it is easy to create duplicate headers without realizing it. This method allows certain headers to be limited in the number of instances of that header that may be added to a `Message` programmatically. (The limit is not observed by the parser, which will faithfully produce as many headers as exist in the message being parsed.)

The default implementation returns `None` for all header names.

header_source_parse(*sourcelines*)
The email package calls this method with a list of strings, each string ending with the line separation characters found in the source being parsed. The first line includes the field header name and separator. All whitespace in the source is preserved. The method should return the `(name, value)` tuple that is to be stored in the `Message` to represent the parsed header.

If an implementation wishes to retain compatibility with the existing email package policies, *name* should be the case preserved name (all characters up to the '`:`' separator), while *value* should be the unfolded value (all line separator characters removed, but whitespace kept intact), stripped of leading whitespace.

sourcelines may contain surrogateescaped binary data.

There is no default implementation

header_store_parse(*name*, *value*)
The email package calls this method with the name and value provided by the application program when the application program is modifying a `Message` programmatically (as opposed to a `Message` created by a parser). The method should return the `(name, value)` tuple that is to be stored in the `Message` to represent the header.

If an implementation wishes to retain compatibility with the existing email package policies, the *name* and *value* should be strings or string subclasses that do not change the content of the passed in arguments.

There is no default implementation

header_fetch_parse(*name*, *value*)
The email package calls this method with the *name* and *value* currently stored in the `Message` when that header is requested by the application program, and whatever the method returns is what is passed back to the application as the value of the header being retrieved. Note that there may be more than one header with the same name stored in the `Message`; the method is passed the specific name and value of the header destined to be returned to the application.

value may contain surrogateescaped binary data. There should be no surrogateescaped binary data in the value returned by the method.

There is no default implementation

fold(*name*, *value*)
The email package calls this method with the *name* and *value* currently stored in the `Message` for a given header. The method should return a string that represents that header "folded" correctly (according to the policy settings) by composing the *name* with the *value* and inserting *linesep* characters at the appropriate places. See **RFC 5322** for a discussion of the rules for folding email headers.

value may contain surrogateescaped binary data. There should be no surrogateescaped binary data in the string returned by the method.

fold_binary(*name*, *value*)
The same as *fold()*, except that the returned value should be a bytes object rather than a string.

value may contain surrogateescaped binary data. These could be converted back into binary data in the returned bytes object.

class email.policy.EmailPolicy(***kw*)
This concrete *Policy* provides behavior that is intended to be fully compliant with the current email RFCs. These include (but are not limited to) **RFC 5322**, **RFC 2047**, and the current MIME RFCs.

This policy adds new header parsing and folding algorithms. Instead of simple strings, headers are `str` subclasses with attributes that depend on the type of the field. The parsing and folding algorithm fully implement **RFC 2047** and **RFC 5322**.

The default value for the *message_factory* attribute is *EmailMessage*.

In addition to the settable attributes listed above that apply to all policies, this policy adds the following additional attributes:

New in version 3.6:[1]

utf8
If `False`, follow **RFC 5322**, supporting non-ASCII characters in headers by encoding them as "encoded words". If `True`, follow **RFC 6532** and use `utf-8` encoding for headers. Messages formatted in this way may be passed to SMTP servers that support the `SMTPUTF8` extension (**RFC 6531**).

refold_source
If the value for a header in the `Message` object originated from a *parser* (as opposed to being set by a program), this attribute indicates whether or not a generator should refold that value when transforming the message back into serialized form. The possible values are:

`none`	all source values use original folding
`long`	source values that have any line that is longer than `max_line_length` will be refolded
`all`	all values are refolded.

The default is `long`.

header_factory
A callable that takes two arguments, `name` and `value`, where `name` is a header field name and `value` is an unfolded header field value, and returns a string subclass that represents that header. A default `header_factory` (see *headerregistry*) is provided that supports custom parsing for the various address and date **RFC 5322** header field types, and the major MIME header field stypes. Support for additional custom parsing will be added in the future.

content_manager
An object with at least two methods: get_content and set_content. When the *get_content()* or *set_content()* method of an *EmailMessage* object is called, it calls the corresponding method

[1] Originally added in 3.3 as a *provisional feature*.

of this object, passing it the message object as its first argument, and any arguments or keywords that were passed to it as additional arguments. By default `content_manager` is set to *raw_data_manager*.

New in version 3.4.

The class provides the following concrete implementations of the abstract methods of *Policy*:

header_max_count(*name*)
Returns the value of the *max_count* attribute of the specialized class used to represent the header with the given name.

header_source_parse(*sourcelines*)
The name is parsed as everything up to the ':' and returned unmodified. The value is determined by stripping leading whitespace off the remainder of the first line, joining all subsequent lines together, and stripping any trailing carriage return or linefeed characters.

header_store_parse(*name*, *value*)
The name is returned unchanged. If the input value has a `name` attribute and it matches *name* ignoring case, the value is returned unchanged. Otherwise the *name* and *value* are passed to `header_factory`, and the resulting header object is returned as the value. In this case a `ValueError` is raised if the input value contains CR or LF characters.

header_fetch_parse(*name*, *value*)
If the value has a `name` attribute, it is returned to unmodified. Otherwise the *name*, and the *value* with any CR or LF characters removed, are passed to the `header_factory`, and the resulting header object is returned. Any surrogateescaped bytes get turned into the unicode unknown-character glyph.

fold(*name*, *value*)
Header folding is controlled by the *refold_source* policy setting. A value is considered to be a 'source value' if and only if it does not have a `name` attribute (having a `name` attribute means it is a header object of some sort). If a source value needs to be refolded according to the policy, it is converted into a header object by passing the *name* and the *value* with any CR and LF characters removed to the `header_factory`. Folding of a header object is done by calling its `fold` method with the current policy.

Source values are split into lines using *splitlines()*. If the value is not to be refolded, the lines are rejoined using the `linesep` from the policy and returned. The exception is lines containing non-ascii binary data. In that case the value is refolded regardless of the `refold_source` setting, which causes the binary data to be CTE encoded using the `unknown-8bit` charset.

fold_binary(*name*, *value*)
The same as *fold()* if *cte_type* is `7bit`, except that the returned value is bytes.

If *cte_type* is `8bit`, non-ASCII binary data is converted back into bytes. Headers with binary data are not refolded, regardless of the `refold_header` setting, since there is no way to know whether the binary data consists of single byte characters or multibyte characters.

The following instances of *EmailPolicy* provide defaults suitable for specific application domains. Note that in the future the behavior of these instances (in particular the `HTTP` instance) may be adjusted to conform even more closely to the RFCs relevant to their domains.

email.policy.default
An instance of `EmailPolicy` with all defaults unchanged. This policy uses the standard Python `\n` line endings rather than the RFC-correct `\r\n`.

email.policy.SMTP
Suitable for serializing messages in conformance with the email RFCs. Like `default`, but with `linesep` set to `\r\n`, which is RFC compliant.

email.policy.SMTPUTF8
: The same as SMTP except that *utf8* is True. Useful for serializing messages to a message store without using encoded words in the headers. Should only be used for SMTP transmission if the sender or recipient addresses have non-ASCII characters (the *smtplib.SMTP.send_message()* method handles this automatically).

email.policy.HTTP
: Suitable for serializing headers with for use in HTTP traffic. Like SMTP except that max_line_length is set to None (unlimited).

email.policy.strict
: Convenience instance. The same as default except that raise_on_defect is set to True. This allows any policy to be made strict by writing:

```
somepolicy + policy.strict
```

With all of these *EmailPolicies*, the effective API of the email package is changed from the Python 3.2 API in the following ways:

- Setting a header on a *Message* results in that header being parsed and a header object created.
- Fetching a header value from a *Message* results in that header being parsed and a header object created and returned.
- Any header object, or any header that is refolded due to the policy settings, is folded using an algorithm that fully implements the RFC folding algorithms, including knowing where encoded words are required and allowed.

From the application view, this means that any header obtained through the *EmailMessage* is a header object with extra attributes, whose string value is the fully decoded unicode value of the header. Likewise, a header may be assigned a new value, or a new header created, using a unicode string, and the policy will take care of converting the unicode string into the correct RFC encoded form.

The header objects and their attributes are described in *headerregistry*.

class email.policy.Compat32(***kw*)
: This concrete *Policy* is the backward compatibility policy. It replicates the behavior of the email package in Python 3.2. The *policy* module also defines an instance of this class, *compat32*, that is used as the default policy. Thus the default behavior of the email package is to maintain compatibility with Python 3.2.

  The following attributes have values that are different from the *Policy* default:

  mangle_from_
  : The default is True.

  The class provides the following concrete implementations of the abstract methods of *Policy*:

  header_source_parse(*sourcelines*)
  : The name is parsed as everything up to the ':' and returned unmodified. The value is determined by stripping leading whitespace off the remainder of the first line, joining all subsequent lines together, and stripping any trailing carriage return or linefeed characters.

  header_store_parse(*name*, *value*)
  : The name and value are returned unmodified.

  header_fetch_parse(*name*, *value*)
  : If the value contains binary data, it is converted into a *Header* object using the unknown-8bit charset. Otherwise it is returned unmodified.

  fold(*name*, *value*)
  : Headers are folded using the *Header* folding algorithm, which preserves existing line breaks in the

value, and wraps each resulting line to the `max_line_length`. Non-ASCII binary data are CTE encoded using the `unknown-8bit` charset.

`fold_binary`(*name*, *value*)
Headers are folded using the *Header* folding algorithm, which preserves existing line breaks in the value, and wraps each resulting line to the `max_line_length`. If `cte_type` is `7bit`, non-ascii binary data is CTE encoded using the `unknown-8bit` charset. Otherwise the original source header is used, with its existing line breaks and any (RFC invalid) binary data it may contain.

`email.policy.compat32`
An instance of *Compat32*, providing backward compatibility with the behavior of the email package in Python 3.2.

20.1.5 `email.errors`: Exception and Defect classes

Source code: Lib/email/errors.py

The following exception classes are defined in the *email.errors* module:

exception `email.errors.MessageError`
This is the base class for all exceptions that the *email* package can raise. It is derived from the standard *Exception* class and defines no additional methods.

exception `email.errors.MessageParseError`
This is the base class for exceptions raised by the *Parser* class. It is derived from *MessageError*. This class is also used internally by the parser used by *headerregistry*.

exception `email.errors.HeaderParseError`
Raised under some error conditions when parsing the **RFC 5322** headers of a message, this class is derived from *MessageParseError*. The *set_boundary()* method will raise this error if the content type is unknown when the method is called. *Header* may raise this error for certain base64 decoding errors, and when an attempt is made to create a header that appears to contain an embedded header (that is, there is what is supposed to be a continuation line that has no leading whitespace and looks like a header).

exception `email.errors.BoundaryError`
Deprecated and no longer used.

exception `email.errors.MultipartConversionError`
Raised when a payload is added to a *Message* object using `add_payload()`, but the payload is already a scalar and the message's *Content-Type* main type is not either *multipart* or missing. *MultipartConversionError* multiply inherits from *MessageError* and the built-in *TypeError*.

Since `Message.add_payload()` is deprecated, this exception is rarely raised in practice. However the exception may also be raised if the *attach()* method is called on an instance of a class derived from *MIMENonMultipart* (e.g. *MIMEImage*).

Here is the list of the defects that the *FeedParser* can find while parsing messages. Note that the defects are added to the message where the problem was found, so for example, if a message nested inside a *multipart/alternative* had a malformed header, that nested message object would have a defect, but the containing messages would not.

All defect classes are subclassed from `email.errors.MessageDefect`.

- `NoBoundaryInMultipartDefect` – A message claimed to be a multipart, but had no *boundary* parameter.
- `StartBoundaryNotFoundDefect` – The start boundary claimed in the *Content-Type* header was never found.

- `CloseBoundaryNotFoundDefect` – A start boundary was found, but no corresponding close boundary was ever found.

  New in version 3.3.

- `FirstHeaderLineIsContinuationDefect` – The message had a continuation line as its first header line.

- `MisplacedEnvelopeHeaderDefect` - A "Unix From" header was found in the middle of a header block.

- `MissingHeaderBodySeparatorDefect` - A line was found while parsing headers that had no leading white space but contained no ':'. Parsing continues assuming that the line represents the first line of the body.

  New in version 3.3.

- `MalformedHeaderDefect` – A header was found that was missing a colon, or was otherwise malformed.

  Deprecated since version 3.3: This defect has not been used for several Python versions.

- `MultipartInvariantViolationDefect` – A message claimed to be a *multipart*, but no subparts were found. Note that when a message has this defect, its *is_multipart()* method may return false even though its content type claims to be *multipart*.

- `InvalidBase64PaddingDefect` – When decoding a block of base64 encoded bytes, the padding was not correct. Enough padding is added to perform the decode, but the resulting decoded bytes may be invalid.

- `InvalidBase64CharactersDefect` – When decoding a block of base64 encoded bytes, characters outside the base64 alphabet were encountered. The characters are ignored, but the resulting decoded bytes may be invalid.

- `InvalidBase64LengthDefect` – When decoding a block of base64 encoded bytes, the number of non-padding base64 characters was invalid (1 more than a multiple of 4). The encoded block was kept as-is.

20.1.6 `email.headerregistry`: Custom Header Objects

Source code: Lib/email/headerregistry.py

New in version 3.6:[1]

Headers are represented by customized subclasses of *str*. The particular class used to represent a given header is determined by the *header_factory* of the *policy* in effect when the headers are created. This section documents the particular `header_factory` implemented by the email package for handling **RFC 5322** compliant email messages, which not only provides customized header objects for various header types, but also provides an extension mechanism for applications to add their own custom header types.

When using any of the policy objects derived from *EmailPolicy*, all headers are produced by *HeaderRegistry* and have *BaseHeader* as their last base class. Each header class has an additional base class that is determined by the type of the header. For example, many headers have the class *UnstructuredHeader* as their other base class. The specialized second class for a header is determined by the name of the header, using a lookup table stored in the *HeaderRegistry*. All of this is managed transparently for the typical application program, but interfaces are provided for modifying the default behavior for use by more complex applications.

The sections below first document the header base classes and their attributes, followed by the API for modifying the behavior of *HeaderRegistry*, and finally the support classes used to represent the data parsed from structured headers.

[1] Originally added in 3.3 as a *provisional module*

class email.headerregistry.BaseHeader(*name*, *value*)

name and *value* are passed to BaseHeader from the *header_factory* call. The string value of any header object is the *value* fully decoded to unicode.

This base class defines the following read-only properties:

name

The name of the header (the portion of the field before the ':'). This is exactly the value passed in the *header_factory* call for *name*; that is, case is preserved.

defects

A tuple of HeaderDefect instances reporting any RFC compliance problems found during parsing. The email package tries to be complete about detecting compliance issues. See the *errors* module for a discussion of the types of defects that may be reported.

max_count

The maximum number of headers of this type that can have the same name. A value of None means unlimited. The BaseHeader value for this attribute is None; it is expected that specialized header classes will override this value as needed.

BaseHeader also provides the following method, which is called by the email library code and should not in general be called by application programs:

fold(***, *policy*)

Return a string containing *linesep* characters as required to correctly fold the header according to *policy*. A *cte_type* of 8bit will be treated as if it were 7bit, since headers may not contain arbitrary binary data. If *utf8* is False, non-ASCII data will be **RFC 2047** encoded.

BaseHeader by itself cannot be used to create a header object. It defines a protocol that each specialized header cooperates with in order to produce the header object. Specifically, BaseHeader requires that the specialized class provide a *classmethod()* named parse. This method is called as follows:

```
parse(string, kwds)
```

kwds is a dictionary containing one pre-initialized key, defects. defects is an empty list. The parse method should append any detected defects to this list. On return, the kwds dictionary *must* contain values for at least the keys decoded and defects. decoded should be the string value for the header (that is, the header value fully decoded to unicode). The parse method should assume that *string* may contain content-transfer-encoded parts, but should correctly handle all valid unicode characters as well so that it can parse un-encoded header values.

BaseHeader's __new__ then creates the header instance, and calls its init method. The specialized class only needs to provide an init method if it wishes to set additional attributes beyond those provided by BaseHeader itself. Such an init method should look like this:

```
def init(self, *args, **kw):
    self._myattr = kw.pop('myattr')
    super().init(*args, **kw)
```

That is, anything extra that the specialized class puts in to the kwds dictionary should be removed and handled, and the remaining contents of kw (and args) passed to the BaseHeader init method.

class email.headerregistry.UnstructuredHeader

An "unstructured" header is the default type of header in **RFC 5322**. Any header that does not have a specified syntax is treated as unstructured. The classic example of an unstructured header is the *Subject* header.

In **RFC 5322**, an unstructured header is a run of arbitrary text in the ASCII character set. **RFC 2047**, however, has an **RFC 5322** compatible mechanism for encoding non-ASCII text as ASCII characters within a header value. When a *value* containing encoded words is passed to the constructor, the UnstructuredHeader parser converts such encoded words into unicode, following the **RFC 2047**

rules for unstructured text. The parser uses heuristics to attempt to decode certain non-compliant encoded words. Defects are registered in such cases, as well as defects for issues such as invalid characters within the encoded words or the non-encoded text.

This header type provides no additional attributes.

class email.headerregistry.DateHeader

RFC 5322 specifies a very specific format for dates within email headers. The `DateHeader` parser recognizes that date format, as well as recognizing a number of variant forms that are sometimes found "in the wild".

This header type provides the following additional attributes:

datetime

If the header value can be recognized as a valid date of one form or another, this attribute will contain a *datetime* instance representing that date. If the timezone of the input date is specified as `-0000` (indicating it is in UTC but contains no information about the source timezone), then *datetime* will be a naive *datetime*. If a specific timezone offset is found (including *+0000*), then *datetime* will contain an aware `datetime` that uses *datetime.timezone* to record the timezone offset.

The `decoded` value of the header is determined by formatting the `datetime` according to the **RFC 5322** rules; that is, it is set to:

```
email.utils.format_datetime(self.datetime)
```

When creating a `DateHeader`, *value* may be *datetime* instance. This means, for example, that the following code is valid and does what one would expect:

```
msg['Date'] = datetime(2011, 7, 15, 21)
```

Because this is a naive `datetime` it will be interpreted as a UTC timestamp, and the resulting value will have a timezone of `-0000`. Much more useful is to use the *localtime()* function from the *utils* module:

```
msg['Date'] = utils.localtime()
```

This example sets the date header to the current time and date using the current timezone offset.

class email.headerregistry.AddressHeader

Address headers are one of the most complex structured header types. The `AddressHeader` class provides a generic interface to any address header.

This header type provides the following additional attributes:

groups

A tuple of *Group* objects encoding the addresses and groups found in the header value. Addresses that are not part of a group are represented in this list as single-address `Groups` whose *display_name* is `None`.

addresses

A tuple of *Address* objects encoding all of the individual addresses from the header value. If the header value contains any groups, the individual addresses from the group are included in the list at the point where the group occurs in the value (that is, the list of addresses is "flattened" into a one dimensional list).

The `decoded` value of the header will have all encoded words decoded to unicode. *idna* encoded domain names are also decoded to unicode. The `decoded` value is set by *join*ing the *str* value of the elements of the `groups` attribute with `', '`.

A list of *Address* and *Group* objects in any combination may be used to set the value of an address header. `Group` objects whose `display_name` is `None` will be interpreted as single addresses, which allows

an address list to be copied with groups intact by using the list obtained from the `groups` attribute of the source header.

class email.headerregistry.SingleAddressHeader
A subclass of *AddressHeader* that adds one additional attribute:

address
The single address encoded by the header value. If the header value actually contains more than one address (which would be a violation of the RFC under the default *policy*), accessing this attribute will result in a *ValueError*.

Many of the above classes also have a `Unique` variant (for example, `UniqueUnstructuredHeader`). The only difference is that in the `Unique` variant, *max_count* is set to 1.

class email.headerregistry.MIMEVersionHeader
There is really only one valid value for the *MIME-Version* header, and that is `1.0`. For future proofing, this header class supports other valid version numbers. If a version number has a valid value per **RFC 2045**, then the header object will have non-`None` values for the following attributes:

version
The version number as a string, with any whitespace and/or comments removed.

major
The major version number as an integer

minor
The minor version number as an integer

class email.headerregistry.ParameterizedMIMEHeader
MIME headers all start with the prefix 'Content-'. Each specific header has a certain value, described under the class for that header. Some can also take a list of supplemental parameters, which have a common format. This class serves as a base for all the MIME headers that take parameters.

params
A dictionary mapping parameter names to parameter values.

class email.headerregistry.ContentTypeHeader
A *ParameterizedMIMEHeader* class that handles the *Content-Type* header.

content_type
The content type string, in the form `maintype/subtype`.

maintype

subtype

class email.headerregistry.ContentDispositionHeader
A *ParameterizedMIMEHeader* class that handles the *Content-Disposition* header.

content-disposition
`inline` and `attachment` are the only valid values in common use.

class email.headerregistry.ContentTransferEncoding
Handles the *Content-Transfer-Encoding* header.

cte
Valid values are `7bit`, `8bit`, `base64`, and `quoted-printable`. See **RFC 2045** for more information.

class email.headerregistry.HeaderRegistry(*base_class=BaseHeader*, *default_class=UnstructuredHeader*, *use_default_map=True*)
This is the factory used by *EmailPolicy* by default. `HeaderRegistry` builds the class used to create a header instance dynamically, using *base_class* and a specialized class retrieved from a registry that it holds. When a given header name does not appear in the registry, the class specified by *default_class*

is used as the specialized class. When *use_default_map* is `True` (the default), the standard mapping of header names to classes is copied in to the registry during initialization. *base_class* is always the last class in the generated class's `__bases__` list.

The default mappings are:

subject UniqueUnstructuredHeader

date UniqueDateHeader

resent-date DateHeader

orig-date UniqueDateHeader

`HeaderRegistry` has the following methods:

`map_to_type`(*self*, *name*, *cls*)
: *name* is the name of the header to be mapped. It will be converted to lower case in the registry. *cls* is the specialized class to be used, along with *base_class*, to create the class used to instantiate headers that match *name*.

`__getitem__`(*name*)
: Construct and return a class to handle creating a *name* header.

`__call__`(*name*, *value*)
: Retrieves the specialized header associated with *name* from the registry (using *default_class* if *name* does not appear in the registry) and composes it with *base_class* to produce a class, calls the constructed class's constructor, passing it the same argument list, and finally returns the class instance created thereby.

The following classes are the classes used to represent data parsed from structured headers and can, in general, be used by an application program to construct structured values to assign to specific headers.

`class email.headerregistry.Address`(*display_name=''*, *username=''*, *domain=''*, *addr_spec=None*)
: The class used to represent an email address. The general form of an address is:

```
[display_name] <username@domain>
```

or:

```
username@domain
```

where each part must conform to specific syntax rules spelled out in **RFC 5322**.

As a convenience *addr_spec* can be specified instead of *username* and *domain*, in which case *username* and *domain* will be parsed from the *addr_spec*. An *addr_spec* must be a properly RFC quoted string; if it is not `Address` will raise an error. Unicode characters are allowed and will be property encoded

when serialized. However, per the RFCs, unicode is *not* allowed in the username portion of the address.

display_name
The display name portion of the address, if any, with all quoting removed. If the address does not have a display name, this attribute will be an empty string.

username
The `username` portion of the address, with all quoting removed.

domain
The `domain` portion of the address.

addr_spec
The `username@domain` portion of the address, correctly quoted for use as a bare address (the second form shown above). This attribute is not mutable.

__str__()
The `str` value of the object is the address quoted according to **RFC 5322** rules, but with no Content Transfer Encoding of any non-ASCII characters.

To support SMTP (**RFC 5321**), `Address` handles one special case: if `username` and `domain` are both the empty string (or `None`), then the string value of the `Address` is `<>`.

class email.headerregistry.Group(*display_name=None*, *addresses=None*)
The class used to represent an address group. The general form of an address group is:

```
display_name: [address-list];
```

As a convenience for processing lists of addresses that consist of a mixture of groups and single addresses, a `Group` may also be used to represent single addresses that are not part of a group by setting *display_name* to `None` and providing a list of the single address as *addresses*.

display_name
The `display_name` of the group. If it is `None` and there is exactly one `Address` in `addresses`, then the `Group` represents a single address that is not in a group.

addresses
A possibly empty tuple of *`Address`* objects representing the addresses in the group.

__str__()
The `str` value of a `Group` is formatted according to **RFC 5322**, but with no Content Transfer Encoding of any non-ASCII characters. If `display_name` is none and there is a single `Address` in the `addresses` list, the `str` value will be the same as the `str` of that single `Address`.

20.1.7 email.contentmanager: Managing MIME Content

Source code: Lib/email/contentmanager.py

New in version 3.6:[1]

class email.contentmanager.ContentManager
Base class for content managers. Provides the standard registry mechanisms to register converters between MIME content and other representations, as well as the `get_content` and `set_content` dispatch methods.

[1] Originally added in 3.4 as a *provisional module*

get_content(*msg*, **args*, ***kw*)
Look up a handler function based on the `mimetype` of *msg* (see next paragraph), call it, passing through all arguments, and return the result of the call. The expectation is that the handler will extract the payload from *msg* and return an object that encodes information about the extracted data.

To find the handler, look for the following keys in the registry, stopping with the first one found:

- the string representing the full MIME type (`maintype/subtype`)
- the string representing the `maintype`
- the empty string

If none of these keys produce a handler, raise a *KeyError* for the full MIME type.

set_content(*msg*, *obj*, **args*, ***kw*)
If the `maintype` is `multipart`, raise a *TypeError*; otherwise look up a handler function based on the type of *obj* (see next paragraph), call *clear_content()* on the *msg*, and call the handler function, passing through all arguments. The expectation is that the handler will transform and store *obj* into *msg*, possibly making other changes to *msg* as well, such as adding various MIME headers to encode information needed to interpret the stored data.

To find the handler, obtain the type of *obj* (`typ = type(obj)`), and look for the following keys in the registry, stopping with the first one found:

- the type itself (`typ`)
- the type's fully qualified name (`typ.__module__ + '.' + typ.__qualname__`).
- the type's qualname (`typ.__qualname__`)
- the type's name (`typ.__name__`).

If none of the above match, repeat all of the checks above for each of the types in the *MRO* (`typ.__mro__`). Finally, if no other key yields a handler, check for a handler for the key `None`. If there is no handler for `None`, raise a *KeyError* for the fully qualified name of the type.

Also add a ***MIME-Version*** header if one is not present (see also *MIMEPart*).

add_get_handler(*key*, *handler*)
Record the function *handler* as the handler for *key*. For the possible values of *key*, see *get_content()*.

add_set_handler(*typekey*, *handler*)
Record *handler* as the function to call when an object of a type matching *typekey* is passed to *set_content()*. For the possible values of *typekey*, see *set_content()*.

Content Manager Instances

Currently the email package provides only one concrete content manager, *raw_data_manager*, although more may be added in the future. *raw_data_manager* is the *content_manager* provided by *EmailPolicy* and its derivatives.

email.contentmanager.raw_data_manager
This content manager provides only a minimum interface beyond that provided by *Message* itself: it deals only with text, raw byte strings, and *Message* objects. Nevertheless, it provides significant advantages compared to the base API: `get_content` on a text part will return a unicode string without the application needing to manually decode it, `set_content` provides a rich set of options for controlling the headers added to a part and controlling the content transfer encoding, and it enables the use of the various `add_` methods, thereby simplifying the creation of multipart messages.

`email.contentmanager.get_content`(*msg*, *errors='replace'*)
Return the payload of the part as either a string (for `text` parts), an *EmailMessage* object (for `message/rfc822` parts), or a `bytes` object (for all other non-multipart types). Raise a *KeyError* if called on a `multipart`. If the part is a `text` part and *errors* is specified, use it as the error handler when decoding the payload to unicode. The default error handler is `replace`.

`email.contentmanager.set_content`(*msg*, *<'str'>*, *subtype="plain"*, *charset='utf-8'* *cte=None*, *disposition=None*, *filename=None*, *cid=None*, *params=None*, *headers=None*)
`email.contentmanager.set_content`(*msg*, *<'bytes'>*, *maintype*, *subtype*, *cte="base64"*, *disposition=None*, *filename=None*, *cid=None*, *params=None*, *headers=None*)
`email.contentmanager.set_content`(*msg*, *<'EmailMessage'>*, *cte=None*, *disposition=None*, *filename=None*, *cid=None*, *params=None*, *headers=None*)
Add headers and payload to *msg*:

Add a *Content-Type* header with a `maintype/subtype` value.

- For `str`, set the MIME `maintype` to `text`, and set the subtype to *subtype* if it is specified, or `plain` if it is not.
- For `bytes`, use the specified *maintype* and *subtype*, or raise a *TypeError* if they are not specified.
- For *EmailMessage* objects, set the maintype to `message`, and set the subtype to *subtype* if it is specified or `rfc822` if it is not. If *subtype* is `partial`, raise an error (`bytes` objects must be used to construct `message/partial` parts).

If *charset* is provided (which is valid only for `str`), encode the string to bytes using the specified character set. The default is `utf-8`. If the specified *charset* is a known alias for a standard MIME charset name, use the standard charset instead.

If *cte* is set, encode the payload using the specified content transfer encoding, and set the *Content-Transfer-Encoding* header to that value. Possible values for *cte* are `quoted-printable`, `base64`, `7bit`, `8bit`, and `binary`. If the input cannot be encoded in the specified encoding (for example, specifying a *cte* of `7bit` for an input that contains non-ASCII values), raise a *ValueError*.

- For `str` objects, if *cte* is not set use heuristics to determine the most compact encoding.
- For *EmailMessage*, per **RFC 2046**, raise an error if a *cte* of `quoted-printable` or `base64` is requested for *subtype* `rfc822`, and for any *cte* other than `7bit` for *subtype* `external-body`. For `message/rfc822`, use `8bit` if *cte* is not specified. For all other values of *subtype*, use `7bit`.

Note: A *cte* of `binary` does not actually work correctly yet. The `EmailMessage` object as modified by `set_content` is correct, but *BytesGenerator* does not serialize it correctly.

If *disposition* is set, use it as the value of the *Content-Disposition* header. If not specified, and *filename* is specified, add the header with the value `attachment`. If *disposition* is not specified and *filename* is also not specified, do not add the header. The only valid values for *disposition* are `attachment` and `inline`.

If *filename* is specified, use it as the value of the `filename` parameter of the *Content-Disposition* header.

If *cid* is specified, add a *Content-ID* header with *cid* as its value.

If *params* is specified, iterate its `items` method and use the resulting `(key, value)` pairs to set additional parameters on the *Content-Type* header.

If *headers* is specified and is a list of strings of the form `headername: headervalue` or a list of `header` objects (distinguished from strings by having a `name` attribute), add the headers to *msg*.

20.1.8 `email`: Examples

Here are a few examples of how to use the *email* package to read, write, and send simple email messages, as well as more complex MIME messages.

First, let's see how to create and send a simple text message (both the text content and the addresses may contain unicode characters):

```
# Import smtplib for the actual sending function
import smtplib

# Import the email modules we'll need
from email.message import EmailMessage

# Open the plain text file whose name is in textfile for reading.
with open(textfile) as fp:
    # Create a text/plain message
    msg = EmailMessage()
    msg.set_content(fp.read())

# me == the sender's email address
# you == the recipient's email address
msg['Subject'] = 'The contents of %s' % textfile
msg['From'] = me
msg['To'] = you

# Send the message via our own SMTP server.
s = smtplib.SMTP('localhost')
s.send_message(msg)
s.quit()
```

Parsing **RFC 822** headers can easily be done by the using the classes from the *parser* module:

```
# Import the email modules we'll need
from email.parser import BytesParser, Parser
from email.policy import default

# If the e-mail headers are in a file, uncomment these two lines:
# with open(messagefile, 'rb') as fp:
#     headers = BytesParser(policy=default).parse(fp)

#  Or for parsing headers in a string (this is an uncommon operation), use:
headers = Parser(policy=default).parsestr(
        'From: Foo Bar <user@example.com>\n'
        'To: <someone_else@example.com>\n'
        'Subject: Test message\n'
        '\n'
        'Body would go here\n')

#  Now the header items can be accessed as a dictionary:
print('To: {}'.format(headers['to']))
print('From: {}'.format(headers['from']))
print('Subject: {}'.format(headers['subject']))
```

(continues on next page)

(continued from previous page)

```
# You can also access the parts of the addresses:
print('Recipient username: {}'.format(headers['to'].addresses[0].username))
print('Sender name: {}'.format(headers['from'].addresses[0].display_name))
```

Here's an example of how to send a MIME message containing a bunch of family pictures that may be residing in a directory:

```
# Import smtplib for the actual sending function
import smtplib

# And imghdr to find the types of our images
import imghdr

# Here are the email package modules we'll need
from email.message import EmailMessage

# Create the container email message.
msg = EmailMessage()
msg['Subject'] = 'Our family reunion'
# me == the sender's email address
# family = the list of all recipients' email addresses
msg['From'] = me
msg['To'] = ', '.join(family)
msg.preamble = 'Our family reunion'

# Open the files in binary mode.  Use imghdr to figure out the
# MIME subtype for each specific image.
for file in pngfiles:
    with open(file, 'rb') as fp:
        img_data = fp.read()
    msg.add_attachment(img_data, maintype='image',
                                 subtype=imghdr.what(None, img_data))

# Send the email via our own SMTP server.
with smtplib.SMTP('localhost') as s:
    s.send_message(msg)
```

Here's an example of how to send the entire contents of a directory as an email message:[1]

```
#!/usr/bin/env python3

"""Send the contents of a directory as a MIME message."""

import os
import smtplib
# For guessing MIME type based on file name extension
import mimetypes

from argparse import ArgumentParser

from email.message import EmailMessage
from email.policy import SMTP

def main():
```

(continues on next page)

[1] Thanks to Matthew Dixon Cowles for the original inspiration and examples.

(continued from previous page)

```
    parser = ArgumentParser(description="""\
Send the contents of a directory as a MIME message.
Unless the -o option is given, the email is sent by forwarding to your local
SMTP server, which then does the normal delivery process.  Your local machine
must be running an SMTP server.
""")
    parser.add_argument('-d', '--directory',
                        help="""Mail the contents of the specified directory,
                        otherwise use the current directory.  Only the regular
                        files in the directory are sent, and we don't recurse to
                        subdirectories.""")
    parser.add_argument('-o', '--output',
                        metavar='FILE',
                        help="""Print the composed message to FILE instead of
                        sending the message to the SMTP server.""")
    parser.add_argument('-s', '--sender', required=True,
                        help='The value of the From: header (required)')
    parser.add_argument('-r', '--recipient', required=True,
                        action='append', metavar='RECIPIENT',
                        default=[], dest='recipients',
                        help='A To: header value (at least one required)')
    args = parser.parse_args()
    directory = args.directory
    if not directory:
        directory = '.'
    # Create the message
    msg = EmailMessage()
    msg['Subject'] = 'Contents of directory %s' % os.path.abspath(directory)
    msg['To'] = ', '.join(args.recipients)
    msg['From'] = args.sender
    msg.preamble = 'You will not see this in a MIME-aware mail reader.\n'

    for filename in os.listdir(directory):
        path = os.path.join(directory, filename)
        if not os.path.isfile(path):
            continue
        # Guess the content type based on the file's extension.  Encoding
        # will be ignored, although we should check for simple things like
        # gzip'd or compressed files.
        ctype, encoding = mimetypes.guess_type(path)
        if ctype is None or encoding is not None:
            # No guess could be made, or the file is encoded (compressed), so
            # use a generic bag-of-bits type.
            ctype = 'application/octet-stream'
        maintype, subtype = ctype.split('/', 1)
        with open(path, 'rb') as fp:
            msg.add_attachment(fp.read(),
                               maintype=maintype,
                               subtype=subtype,
                               filename=filename)
    # Now send or store the message
    if args.output:
        with open(args.output, 'wb') as fp:
            fp.write(msg.as_bytes(policy=SMTP))
    else:
        with smtplib.SMTP('localhost') as s:
```

(continues on next page)

(continued from previous page)

```
            s.send_message(msg)

if __name__ == '__main__':
    main()
```

Here's an example of how to unpack a MIME message like the one above, into a directory of files:

```
#!/usr/bin/env python3

"""Unpack a MIME message into a directory of files."""

import os
import email
import mimetypes

from email.policy import default

from argparse import ArgumentParser

def main():
    parser = ArgumentParser(description="""\
Unpack a MIME message into a directory of files.
""")
    parser.add_argument('-d', '--directory', required=True,
                        help="""Unpack the MIME message into the named
                        directory, which will be created if it doesn't already
                        exist.""")
    parser.add_argument('msgfile')
    args = parser.parse_args()

    with open(args.msgfile, 'rb') as fp:
        msg = email.message_from_binary_file(fp, policy=default)

    try:
        os.mkdir(args.directory)
    except FileExistsError:
        pass

    counter = 1
    for part in msg.walk():
        # multipart/* are just containers
        if part.get_content_maintype() == 'multipart':
            continue
        # Applications should really sanitize the given filename so that an
        # email message can't be used to overwrite important files
        filename = part.get_filename()
        if not filename:
            ext = mimetypes.guess_extension(part.get_content_type())
            if not ext:
                # Use a generic bag-of-bits extension
                ext = '.bin'
            filename = 'part-%03d%s' % (counter, ext)
        counter += 1
        with open(os.path.join(args.directory, filename), 'wb') as fp:
```

(continues on next page)

(continued from previous page)

```
            fp.write(part.get_payload(decode=True))

if __name__ == '__main__':
    main()
```

Here's an example of how to create an HTML message with an alternative plain text version. To make things a bit more interesting, we include a related image in the html part, and we save a copy of what we are going to send to disk, as well as sending it.

```
#!/usr/bin/env python3

import smtplib

from email.message import EmailMessage
from email.headerregistry import Address
from email.utils import make_msgid

# Create the base text message.
msg = EmailMessage()
msg['Subject'] = "Ayons asperges pour le déjeuner"
msg['From'] = Address("Pepé Le Pew", "pepe", "example.com")
msg['To'] = (Address("Penelope Pussycat", "penelope", "example.com"),
             Address("Fabrette Pussycat", "fabrette", "example.com"))
msg.set_content("""\
Salut!

Cela ressemble à un excellent recipie[1] déjeuner.

[1] http://www.yummly.com/recipe/Roasted-Asparagus-Epicurious-203718

--Pepé
""")

# Add the html version.  This converts the message into a multipart/alternative
# container, with the original text message as the first part and the new html
# message as the second part.
asparagus_cid = make_msgid()
msg.add_alternative("""\
<html>
  <head></head>
  <body>
    <p>Salut!</p>
    <p>Cela ressemble à un excellent
        <a href="http://www.yummly.com/recipe/Roasted-Asparagus-Epicurious-203718">
            recipie
        </a> déjeuner.
    </p>
    <img src="cid:{asparagus_cid}" />
  </body>
</html>
""".format(asparagus_cid=asparagus_cid[1:-1]), subtype='html')
# note that we needed to peel the <> off the msgid for use in the html.

# Now add the related image to the html part.
with open("roasted-asparagus.jpg", 'rb') as img:
```

(continues on next page)

(continued from previous page)

```
    msg.get_payload()[1].add_related(img.read(), 'image', 'jpeg',
                                     cid=asparagus_cid)

# Make a local copy of what we are going to send.
with open('outgoing.msg', 'wb') as f:
    f.write(bytes(msg))

# Send the message via local SMTP server.
with smtplib.SMTP('localhost') as s:
    s.send_message(msg)
```

If we were sent the message from the last example, here is one way we could process it:

```
import os
import sys
import tempfile
import mimetypes
import webbrowser

# Import the email modules we'll need
from email import policy
from email.parser import BytesParser

# An imaginary module that would make this work and be safe.
from imaginary import magic_html_parser

# In a real program you'd get the filename from the arguments.
with open('outgoing.msg', 'rb') as fp:
    msg = BytesParser(policy=policy.default).parse(fp)

# Now the header items can be accessed as a dictionary, and any non-ASCII will
# be converted to unicode:
print('To:', msg['to'])
print('From:', msg['from'])
print('Subject:', msg['subject'])

# If we want to print a preview of the message content, we can extract whatever
# the least formatted payload is and print the first three lines.  Of course,
# if the message has no plain text part printing the first three lines of html
# is probably useless, but this is just a conceptual example.
simplest = msg.get_body(preferencelist=('plain', 'html'))
print()
print(''.join(simplest.get_content().splitlines(keepends=True)[:3]))

ans = input("View full message?")
if ans.lower()[0] == 'n':
    sys.exit()

# We can extract the richest alternative in order to display it:
richest = msg.get_body()
partfiles = {}
if richest['content-type'].maintype == 'text':
    if richest['content-type'].subtype == 'plain':
        for line in richest.get_content().splitlines():
            print(line)
        sys.exit()
```

(continues on next page)

(continued from previous page)

```
    elif richest['content-type'].subtype == 'html':
        body = richest
    else:
        print("Don't know how to display {}".format(richest.get_content_type()))
        sys.exit()
elif richest['content-type'].content_type == 'multipart/related':
    body = richest.get_body(preferencelist=('html'))
    for part in richest.iter_attachments():
        fn = part.get_filename()
        if fn:
            extension = os.path.splitext(part.get_filename())[1]
        else:
            extension = mimetypes.guess_extension(part.get_content_type())
        with tempfile.NamedTemporaryFile(suffix=extension, delete=False) as f:
            f.write(part.get_content())
            # again strip the <> to go from email form of cid to html form.
            partfiles[part['content-id'][1:-1]] = f.name
else:
    print("Don't know how to display {}".format(richest.get_content_type()))
    sys.exit()
with tempfile.NamedTemporaryFile(mode='w', delete=False) as f:
    # The magic_html_parser has to rewrite the href="cid:...." attributes to
    # point to the filenames in partfiles.  It also has to do a safety-sanitize
    # of the html.  It could be written using html.parser.
    f.write(magic_html_parser(body.get_content(), partfiles))
webbrowser.open(f.name)
os.remove(f.name)
for fn in partfiles.values():
    os.remove(fn)

# Of course, there are lots of email messages that could break this simple
# minded program, but it will handle the most common ones.
```

Up to the prompt, the output from the above is:

```
To: Penelope Pussycat <penelope@example.com>, Fabrette Pussycat <fabrette@example.com>
From: Pepé Le Pew <pepe@example.com>
Subject: Ayons asperges pour le déjeuner

Salut!

Cela ressemble à un excellent recipie[1] déjeuner.
```

Legacy API:

20.1.9 email.message.Message: Representing an email message using the compat32 API

The *Message* class is very similar to the *EmailMessage* class, without the methods added by that class, and with the default behavior of certain other methods being slightly different. We also document here some methods that, while supported by the *EmailMessage* class, are not recommended unless you are dealing with legacy code.

The philosophy and structure of the two classes is otherwise the same.

This document describes the behavior under the default (for *Message*) policy *Compat32*. If you are going to use another policy, you should be using the *EmailMessage* class instead.

An email message consists of *headers* and a *payload*. Headers must be **RFC 5233** style names and values, where the field name and value are separated by a colon. The colon is not part of either the field name or the field value. The payload may be a simple text message, or a binary object, or a structured sequence of sub-messages each with their own set of headers and their own payload. The latter type of payload is indicated by the message having a MIME type such as *multipart/** or *message/rfc822*.

The conceptual model provided by a *Message* object is that of an ordered dictionary of headers with additional methods for accessing both specialized information from the headers, for accessing the payload, for generating a serialized version of the message, and for recursively walking over the object tree. Note that duplicate headers are supported but special methods must be used to access them.

The *Message* pseudo-dictionary is indexed by the header names, which must be ASCII values. The values of the dictionary are strings that are supposed to contain only ASCII characters; there is some special handling for non-ASCII input, but it doesn't always produce the correct results. Headers are stored and returned in case-preserving form, but field names are matched case-insensitively. There may also be a single envelope header, also known as the *Unix-From* header or the `From_` header. The *payload* is either a string or bytes, in the case of simple message objects, or a list of *Message* objects, for MIME container documents (e.g. *multipart/** and *message/rfc822*).

Here are the methods of the *Message* class:

class email.message.Message(*policy=compat32*)

If *policy* is specified (it must be an instance of a *policy* class) use the rules it specifies to update and serialize the representation of the message. If *policy* is not set, use the *compat32* policy, which maintains backward compatibility with the Python 3.2 version of the email package. For more information see the *policy* documentation.

Changed in version 3.3: The *policy* keyword argument was added.

as_string(*unixfrom=False*, *maxheaderlen=0*, *policy=None*)

Return the entire message flattened as a string. When optional *unixfrom* is true, the envelope header is included in the returned string. *unixfrom* defaults to `False`. For backward compatibility reasons, *maxheaderlen* defaults to `0`, so if you want a different value you must override it explicitly (the value specified for *max_line_length* in the policy will be ignored by this method). The *policy* argument may be used to override the default policy obtained from the message instance. This can be used to control some of the formatting produced by the method, since the specified *policy* will be passed to the `Generator`.

Flattening the message may trigger changes to the *Message* if defaults need to be filled in to complete the transformation to a string (for example, MIME boundaries may be generated or modified).

Note that this method is provided as a convenience and may not always format the message the way you want. For example, by default it does not do the mangling of lines that begin with `From` that is required by the unix mbox format. For more flexibility, instantiate a *Generator* instance and use its *flatten()* method directly. For example:

```
from io import StringIO
from email.generator import Generator
fp = StringIO()
g = Generator(fp, mangle_from_=True, maxheaderlen=60)
g.flatten(msg)
text = fp.getvalue()
```

If the message object contains binary data that is not encoded according to RFC standards, the non-compliant data will be replaced by unicode "unknown character" code points. (See also *as_bytes()* and *BytesGenerator*.)

Changed in version 3.4: the *policy* keyword argument was added.

__str__()
Equivalent to *as_string()*. Allows `str(msg)` to produce a string containing the formatted message.

as_bytes(*unixfrom=False*, *policy=None*)
Return the entire message flattened as a bytes object. When optional *unixfrom* is true, the envelope header is included in the returned string. *unixfrom* defaults to `False`. The *policy* argument may be used to override the default policy obtained from the message instance. This can be used to control some of the formatting produced by the method, since the specified *policy* will be passed to the `BytesGenerator`.

Flattening the message may trigger changes to the *Message* if defaults need to be filled in to complete the transformation to a string (for example, MIME boundaries may be generated or modified).

Note that this method is provided as a convenience and may not always format the message the way you want. For example, by default it does not do the mangling of lines that begin with `From` that is required by the unix mbox format. For more flexibility, instantiate a *BytesGenerator* instance and use its *flatten()* method directly. For example:

```
from io import BytesIO
from email.generator import BytesGenerator
fp = BytesIO()
g = BytesGenerator(fp, mangle_from_=True, maxheaderlen=60)
g.flatten(msg)
text = fp.getvalue()
```

New in version 3.4.

__bytes__()
Equivalent to *as_bytes()*. Allows `bytes(msg)` to produce a bytes object containing the formatted message.

New in version 3.4.

is_multipart()
Return `True` if the message's payload is a list of sub-*Message* objects, otherwise return `False`. When *is_multipart()* returns `False`, the payload should be a string object (which might be a CTE encoded binary payload. (Note that *is_multipart()* returning `True` does not necessarily mean that "msg.get_content_maintype() == 'multipart'" will return the `True`. For example, `is_multipart` will return `True` when the *Message* is of type `message/rfc822`.)

set_unixfrom(*unixfrom*)
Set the message's envelope header to *unixfrom*, which should be a string.

get_unixfrom()
Return the message's envelope header. Defaults to `None` if the envelope header was never set.

attach(*payload*)
Add the given *payload* to the current payload, which must be `None` or a list of *Message* objects before the call. After the call, the payload will always be a list of *Message* objects. If you want to set the payload to a scalar object (e.g. a string), use *set_payload()* instead.

This is a legacy method. On the `EmailMessage` class its functionality is replaced by *set_content()* and the related `make` and `add` methods.

get_payload(*i=None*, *decode=False*)
Return the current payload, which will be a list of *Message* objects when *is_multipart()* is `True`, or a string when *is_multipart()* is `False`. If the payload is a list and you mutate the list object, you modify the message's payload in place.

With optional argument *i*, *get_payload()* will return the *i*-th element of the payload, counting from zero, if *is_multipart()* is `True`. An *IndexError* will be raised if *i* is less than 0 or greater than or equal to the number of items in the payload. If the payload is a string (i.e. *is_multipart()* is `False`) and *i* is given, a *TypeError* is raised.

Optional *decode* is a flag indicating whether the payload should be decoded or not, according to the *Content-Transfer-Encoding* header. When `True` and the message is not a multipart, the payload will be decoded if this header's value is `quoted-printable` or `base64`. If some other encoding is used, or *Content-Transfer-Encoding* header is missing, the payload is returned as-is (undecoded). In all cases the returned value is binary data. If the message is a multipart and the *decode* flag is `True`, then `None` is returned. If the payload is base64 and it was not perfectly formed (missing padding, characters outside the base64 alphabet), then an appropriate defect will be added to the message's defect property (`InvalidBase64PaddingDefect` or `InvalidBase64CharactersDefect`, respectively).

When *decode* is `False` (the default) the body is returned as a string without decoding the *Content-Transfer-Encoding*. However, for a *Content-Transfer-Encoding* of 8bit, an attempt is made to decode the original bytes using the `charset` specified by the *Content-Type* header, using the `replace` error handler. If no `charset` is specified, or if the `charset` given is not recognized by the email package, the body is decoded using the default ASCII charset.

This is a legacy method. On the `EmailMessage` class its functionality is replaced by *get_content()* and *iter_parts()*.

set_payload(*payload*, *charset=None*)
Set the entire message object's payload to *payload*. It is the client's responsibility to ensure the payload invariants. Optional *charset* sets the message's default character set; see *set_charset()* for details.

This is a legacy method. On the `EmailMessage` class its functionality is replaced by *set_content()*.

set_charset(*charset*)
Set the character set of the payload to *charset*, which can either be a *Charset* instance (see *email.charset*), a string naming a character set, or `None`. If it is a string, it will be converted to a *Charset* instance. If *charset* is `None`, the `charset` parameter will be removed from the *Content-Type* header (the message will not be otherwise modified). Anything else will generate a *TypeError*.

If there is no existing *MIME-Version* header one will be added. If there is no existing *Content-Type* header, one will be added with a value of *text/plain*. Whether the *Content-Type* header already exists or not, its `charset` parameter will be set to *charset.output_charset*. If *charset.input_charset* and *charset.output_charset* differ, the payload will be re-encoded to the *output_charset*. If there is no existing *Content-Transfer-Encoding* header, then the payload will be transfer-encoded, if needed, using the specified *Charset*, and a header with the appropriate value will be added. If a *Content-Transfer-Encoding* header already exists, the payload is assumed to already be correctly encoded using that *Content-Transfer-Encoding* and is not modified.

This is a legacy method. On the `EmailMessage` class its functionality is replaced by the *charset* parameter of the `email.emailmessage.EmailMessage.set_content()` method.

get_charset()
Return the *Charset* instance associated with the message's payload.

This is a legacy method. On the `EmailMessage` class it always returns `None`.

The following methods implement a mapping-like interface for accessing the message's **RFC 2822** headers. Note that there are some semantic differences between these methods and a normal mapping (i.e. dictionary) interface. For example, in a dictionary there are no duplicate keys, but here there may be duplicate message headers. Also, in dictionaries there is no guaranteed order to the keys returned

by *keys()*, but in a *Message* object, headers are always returned in the order they appeared in the original message, or were added to the message later. Any header deleted and then re-added are always appended to the end of the header list.

These semantic differences are intentional and are biased toward maximal convenience.

Note that in all cases, any envelope header present in the message is not included in the mapping interface.

In a model generated from bytes, any header values that (in contravention of the RFCs) contain non-ASCII bytes will, when retrieved through this interface, be represented as *Header* objects with a charset of *unknown-8bit*.

__len__()
Return the total number of headers, including duplicates.

__contains__(*name*)
Return true if the message object has a field named *name*. Matching is done case-insensitively and *name* should not include the trailing colon. Used for the `in` operator, e.g.:

```
if 'message-id' in myMessage:
   print('Message-ID:', myMessage['message-id'])
```

__getitem__(*name*)
Return the value of the named header field. *name* should not include the colon field separator. If the header is missing, `None` is returned; a *KeyError* is never raised.

Note that if the named field appears more than once in the message's headers, exactly which of those field values will be returned is undefined. Use the *get_all()* method to get the values of all the extant named headers.

__setitem__(*name*, *val*)
Add a header to the message with field name *name* and value *val*. The field is appended to the end of the message's existing fields.

Note that this does *not* overwrite or delete any existing header with the same name. If you want to ensure that the new header is the only one present in the message with field name *name*, delete the field first, e.g.:

```
del msg['subject']
msg['subject'] = 'Python roolz!'
```

__delitem__(*name*)
Delete all occurrences of the field with name *name* from the message's headers. No exception is raised if the named field isn't present in the headers.

keys()
Return a list of all the message's header field names.

values()
Return a list of all the message's field values.

items()
Return a list of 2-tuples containing all the message's field headers and values.

get(*name*, *failobj=None*)
Return the value of the named header field. This is identical to *__getitem__()* except that optional *failobj* is returned if the named header is missing (defaults to `None`).

Here are some additional useful methods:

get_all(*name*, *failobj=None*)
Return a list of all the values for the field named *name*. If there are no such named headers in the message, *failobj* is returned (defaults to `None`).

add_header(*_name*, *_value*, ***_params*)
Extended header setting. This method is similar to *__setitem__()* except that additional header parameters can be provided as keyword arguments. *_name* is the header field to add and *_value* is the *primary* value for the header.

For each item in the keyword argument dictionary *_params*, the key is taken as the parameter name, with underscores converted to dashes (since dashes are illegal in Python identifiers). Normally, the parameter will be added as `key="value"` unless the value is `None`, in which case only the key will be added. If the value contains non-ASCII characters, it can be specified as a three tuple in the format `(CHARSET, LANGUAGE, VALUE)`, where `CHARSET` is a string naming the charset to be used to encode the value, `LANGUAGE` can usually be set to `None` or the empty string (see **RFC 2231** for other possibilities), and `VALUE` is the string value containing non-ASCII code points. If a three tuple is not passed and the value contains non-ASCII characters, it is automatically encoded in **RFC 2231** format using a `CHARSET` of `utf-8` and a `LANGUAGE` of `None`.

Here's an example:

```
msg.add_header('Content-Disposition', 'attachment', filename='bud.gif')
```

This will add a header that looks like

```
Content-Disposition: attachment; filename="bud.gif"
```

An example with non-ASCII characters:

```
msg.add_header('Content-Disposition', 'attachment',
               filename=('iso-8859-1', '', 'Fußballer.ppt'))
```

Which produces

```
Content-Disposition: attachment; filename*="iso-8859-1''Fu%DFballer.ppt"
```

replace_header(*_name*, *_value*)
Replace a header. Replace the first header found in the message that matches *_name*, retaining header order and field name case. If no matching header was found, a *KeyError* is raised.

get_content_type()
Return the message's content type. The returned string is coerced to lower case of the form *maintype/subtype*. If there was no *Content-Type* header in the message the default type as given by *get_default_type()* will be returned. Since according to **RFC 2045**, messages always have a default type, *get_content_type()* will always return a value.

RFC 2045 defines a message's default type to be *text/plain* unless it appears inside a *multipart/digest* container, in which case it would be *message/rfc822*. If the *Content-Type* header has an invalid type specification, **RFC 2045** mandates that the default type be *text/plain*.

get_content_maintype()
Return the message's main content type. This is the *maintype* part of the string returned by *get_content_type()*.

get_content_subtype()
Return the message's sub-content type. This is the *subtype* part of the string returned by *get_content_type()*.

get_default_type()
Return the default content type. Most messages have a default content type of *text/plain*, except for messages that are subparts of *multipart/digest* containers. Such subparts have a default content type of *message/rfc822*.

set_default_type(*ctype*)
Set the default content type. *ctype* should either be *text/plain* or *message/rfc822*, although this is not enforced. The default content type is not stored in the *Content-Type* header.

get_params(*failobj=None*, *header='content-type'*, *unquote=True*)
Return the message's *Content-Type* parameters, as a list. The elements of the returned list are 2-tuples of key/value pairs, as split on the `'='` sign. The left hand side of the `'='` is the key, while the right hand side is the value. If there is no `'='` sign in the parameter the value is the empty string, otherwise the value is as described in *get_param()* and is unquoted if optional *unquote* is `True` (the default).

Optional *failobj* is the object to return if there is no *Content-Type* header. Optional *header* is the header to search instead of *Content-Type*.

This is a legacy method. On the `EmailMessage` class its functionality is replaced by the *params* property of the individual header objects returned by the header access methods.

get_param(*param*, *failobj=None*, *header='content-type'*, *unquote=True*)
Return the value of the *Content-Type* header's parameter *param* as a string. If the message has no *Content-Type* header or if there is no such parameter, then *failobj* is returned (defaults to `None`).

Optional *header* if given, specifies the message header to use instead of *Content-Type*.

Parameter keys are always compared case insensitively. The return value can either be a string, or a 3-tuple if the parameter was **RFC 2231** encoded. When it's a 3-tuple, the elements of the value are of the form `(CHARSET, LANGUAGE, VALUE)`. Note that both `CHARSET` and `LANGUAGE` can be `None`, in which case you should consider `VALUE` to be encoded in the `us-ascii` charset. You can usually ignore `LANGUAGE`.

If your application doesn't care whether the parameter was encoded as in **RFC 2231**, you can collapse the parameter value by calling *email.utils.collapse_rfc2231_value()*, passing in the return value from *get_param()*. This will return a suitably decoded Unicode string when the value is a tuple, or the original string unquoted if it isn't. For example:

```
rawparam = msg.get_param('foo')
param = email.utils.collapse_rfc2231_value(rawparam)
```

In any case, the parameter value (either the returned string, or the `VALUE` item in the 3-tuple) is always unquoted, unless *unquote* is set to `False`.

This is a legacy method. On the `EmailMessage` class its functionality is replaced by the *params* property of the individual header objects returned by the header access methods.

set_param(*param*, *value*, *header='Content-Type'*, *requote=True*, *charset=None*, *language=''*, *replace=False*)
Set a parameter in the *Content-Type* header. If the parameter already exists in the header, its value will be replaced with *value*. If the *Content-Type* header as not yet been defined for this message, it will be set to *text/plain* and the new parameter value will be appended as per **RFC 2045**.

Optional *header* specifies an alternative header to *Content-Type*, and all parameters will be quoted as necessary unless optional *requote* is `False` (the default is `True`).

If optional *charset* is specified, the parameter will be encoded according to **RFC 2231**. Optional *language* specifies the RFC 2231 language, defaulting to the empty string. Both *charset* and *language* should be strings.

If *replace* is `False` (the default) the header is moved to the end of the list of headers. If *replace* is `True`, the header will be updated in place.

Changed in version 3.4: `replace` keyword was added.

del_param(*param*, *header='content-type'*, *requote=True*)
Remove the given parameter completely from the *Content-Type* header. The header will be rewritten in place without the parameter or its value. All values will be quoted as necessary unless *requote* is `False` (the default is `True`). Optional *header* specifies an alternative to *Content-Type*.

set_type(*type*, *header='Content-Type'*, *requote=True*)
Set the main type and subtype for the *Content-Type* header. *type* must be a string in the form *maintype/subtype*, otherwise a *ValueError* is raised.

This method replaces the *Content-Type* header, keeping all the parameters in place. If *requote* is `False`, this leaves the existing header's quoting as is, otherwise the parameters will be quoted (the default).

An alternative header can be specified in the *header* argument. When the *Content-Type* header is set a *MIME-Version* header is also added.

This is a legacy method. On the `EmailMessage` class its functionality is replaced by the `make_` and `add_` methods.

get_filename(*failobj=None*)
Return the value of the `filename` parameter of the *Content-Disposition* header of the message. If the header does not have a `filename` parameter, this method falls back to looking for the `name` parameter on the *Content-Type* header. If neither is found, or the header is missing, then *failobj* is returned. The returned string will always be unquoted as per *email.utils.unquote()*.

get_boundary(*failobj=None*)
Return the value of the `boundary` parameter of the *Content-Type* header of the message, or *failobj* if either the header is missing, or has no `boundary` parameter. The returned string will always be unquoted as per *email.utils.unquote()*.

set_boundary(*boundary*)
Set the `boundary` parameter of the *Content-Type* header to *boundary*. *set_boundary()* will always quote *boundary* if necessary. A *HeaderParseError* is raised if the message object has no *Content-Type* header.

Note that using this method is subtly different than deleting the old *Content-Type* header and adding a new one with the new boundary via *add_header()*, because *set_boundary()* preserves the order of the *Content-Type* header in the list of headers. However, it does *not* preserve any continuation lines which may have been present in the original *Content-Type* header.

get_content_charset(*failobj=None*)
Return the `charset` parameter of the *Content-Type* header, coerced to lower case. If there is no *Content-Type* header, or if that header has no `charset` parameter, *failobj* is returned.

Note that this method differs from *get_charset()* which returns the *Charset* instance for the default encoding of the message body.

get_charsets(*failobj=None*)
Return a list containing the character set names in the message. If the message is a *multipart*, then the list will contain one element for each subpart in the payload, otherwise, it will be a list of length 1.

Each item in the list will be a string which is the value of the `charset` parameter in the *Content-Type* header for the represented subpart. However, if the subpart has no *Content-Type* header, no `charset` parameter, or is not of the *text* main MIME type, then that item in the returned list will be *failobj*.

get_content_disposition()
Return the lowercased value (without parameters) of the message's *Content-Disposition* header if it has one, or `None`. The possible values for this method are *inline*, *attachment* or `None` if the message follows **RFC 2183**.

New in version 3.5.

walk()
The *walk()* method is an all-purpose generator which can be used to iterate over all the parts and subparts of a message object tree, in depth-first traversal order. You will typically use *walk()* as the iterator in a `for` loop; each iteration returns the next subpart.

Here's an example that prints the MIME type of every part of a multipart message structure:

```
>>> for part in msg.walk():
...     print(part.get_content_type())
multipart/report
text/plain
message/delivery-status
text/plain
text/plain
message/rfc822
text/plain
```

`walk` iterates over the subparts of any part where *is_multipart()* returns `True`, even though `msg.get_content_maintype() == 'multipart'` may return `False`. We can see this in our example by making use of the `_structure` debug helper function:

```
>>> for part in msg.walk():
...     print(part.get_content_maintype() == 'multipart',
...           part.is_multipart())
True True
False False
False True
False False
False False
False True
False False
>>> _structure(msg)
multipart/report
    text/plain
    message/delivery-status
        text/plain
        text/plain
    message/rfc822
        text/plain
```

Here the `message` parts are not `multiparts`, but they do contain subparts. `is_multipart()` returns `True` and `walk` descends into the subparts.

Message objects can also optionally contain two instance attributes, which can be used when generating the plain text of a MIME message.

preamble
The format of a MIME document allows for some text between the blank line following the headers, and the first multipart boundary string. Normally, this text is never visible in a MIME-aware mail reader because it falls outside the standard MIME armor. However, when viewing the raw text of the message, or when viewing the message in a non-MIME aware reader, this text can become visible.

The *preamble* attribute contains this leading extra-armor text for MIME documents. When the *Parser* discovers some text after the headers but before the first boundary string, it assigns this text to the message's *preamble* attribute. When the *Generator* is writing out the plain text representation of a MIME message, and it finds the message has a *preamble* attribute, it will write this text in the area between the headers and the first boundary. See *email.parser* and *email.generator* for details.

Note that if the message object has no preamble, the *preamble* attribute will be `None`.

epilogue
The *epilogue* attribute acts the same way as the *preamble* attribute, except that it contains text that appears between the last boundary and the end of the message.

You do not need to set the epilogue to the empty string in order for the *Generator* to print a newline at the end of the file.

defects
The *defects* attribute contains a list of all the problems found when parsing this message. See *email.errors* for a detailed description of the possible parsing defects.

20.1.10 email.mime: Creating email and MIME objects from scratch

Source code: Lib/email/mime/

This module is part of the legacy (`Compat32`) email API. Its functionality is partially replaced by the *contentmanager* in the new API, but in certain applications these classes may still be useful, even in non-legacy code.

Ordinarily, you get a message object structure by passing a file or some text to a parser, which parses the text and returns the root message object. However you can also build a complete message structure from scratch, or even individual *Message* objects by hand. In fact, you can also take an existing structure and add new *Message* objects, move them around, etc. This makes a very convenient interface for slicing-and-dicing MIME messages.

You can create a new object structure by creating *Message* instances, adding attachments and all the appropriate headers manually. For MIME messages though, the *email* package provides some convenient subclasses to make things easier.

Here are the classes:

class email.mime.base.MIMEBase(*_maintype*, *_subtype*, ***, *policy=compat32*, ***_params*)
Module: `email.mime.base`

This is the base class for all the MIME-specific subclasses of *Message*. Ordinarily you won't create instances specifically of *MIMEBase*, although you could. *MIMEBase* is provided primarily as a convenient base class for more specific MIME-aware subclasses.

_maintype is the *Content-Type* major type (e.g. *text* or *image*), and *_subtype* is the *Content-Type* minor type (e.g. *plain* or *gif*). *_params* is a parameter key/value dictionary and is passed directly to *Message.add_header*.

If *policy* is specified, (defaults to the *compat32* policy) it will be passed to *Message*.

The *MIMEBase* class always adds a *Content-Type* header (based on *_maintype*, *_subtype*, and *_params*), and a *MIME-Version* header (always set to `1.0`).

Changed in version 3.6: Added *policy* keyword-only parameter.

class email.mime.nonmultipart.MIMENonMultipart

Module: email.mime.nonmultipart

A subclass of *MIMEBase*, this is an intermediate base class for MIME messages that are not *multipart*. The primary purpose of this class is to prevent the use of the *attach()* method, which only makes sense for *multipart* messages. If *attach()* is called, a *MultipartConversionError* exception is raised.

class email.mime.multipart.MIMEMultipart(*_subtype='mixed'*, *boundary=None*, *_subparts=None*, ***, *policy=compat32*, ***_params*)

Module: email.mime.multipart

A subclass of *MIMEBase*, this is an intermediate base class for MIME messages that are *multipart*. Optional *_subtype* defaults to *mixed*, but can be used to specify the subtype of the message. A *Content-Type* header of *multipart/_subtype* will be added to the message object. A *MIME-Version* header will also be added.

Optional *boundary* is the multipart boundary string. When None (the default), the boundary is calculated when needed (for example, when the message is serialized).

_subparts is a sequence of initial subparts for the payload. It must be possible to convert this sequence to a list. You can always attach new subparts to the message by using the *Message.attach* method.

Optional *policy* argument defaults to *compat32*.

Additional parameters for the *Content-Type* header are taken from the keyword arguments, or passed into the *_params* argument, which is a keyword dictionary.

Changed in version 3.6: Added *policy* keyword-only parameter.

class email.mime.application.MIMEApplication(*_data*, *_subtype='octet-stream'*, *_encoder=email.encoders.encode_base64*, ***, *policy=compat32*, ***_params*)

Module: email.mime.application

A subclass of *MIMENonMultipart*, the *MIMEApplication* class is used to represent MIME message objects of major type *application*. *_data* is a string containing the raw byte data. Optional *_subtype* specifies the MIME subtype and defaults to *octet-stream*.

Optional *_encoder* is a callable (i.e. function) which will perform the actual encoding of the data for transport. This callable takes one argument, which is the *MIMEApplication* instance. It should use *get_payload()* and *set_payload()* to change the payload to encoded form. It should also add any *Content-Transfer-Encoding* or other headers to the message object as necessary. The default encoding is base64. See the *email.encoders* module for a list of the built-in encoders.

Optional *policy* argument defaults to *compat32*.

_params are passed straight through to the base class constructor.

Changed in version 3.6: Added *policy* keyword-only parameter.

class email.mime.audio.MIMEAudio(*_audiodata*, *_subtype=None*, *_encoder=email.encoders.encode_base64*, ***, *policy=compat32*, ***_params*)

Module: email.mime.audio

A subclass of *MIMENonMultipart*, the *MIMEAudio* class is used to create MIME message objects of major type *audio*. *_audiodata* is a string containing the raw audio data. If this data can be decoded by the standard Python module *sndhdr*, then the subtype will be automatically included in the *Content-Type* header. Otherwise you can explicitly specify the audio subtype via the *_subtype* argument. If the minor type could not be guessed and *_subtype* was not given, then *TypeError* is raised.

Optional *_encoder* is a callable (i.e. function) which will perform the actual encoding of the audio data for transport. This callable takes one argument, which is the *MIMEAudio* instance. It should use *get_payload()* and *set_payload()* to change the payload to encoded form. It should also add

any *Content-Transfer-Encoding* or other headers to the message object as necessary. The default encoding is base64. See the *email.encoders* module for a list of the built-in encoders.

Optional *policy* argument defaults to *compat32*.

_params are passed straight through to the base class constructor.

Changed in version 3.6: Added *policy* keyword-only parameter.

class email.mime.image.MIMEImage(*_imagedata*, *_subtype=None*, *_encoder=email.encoders.encode_base64*, ***, *policy=compat32*, ***_params*)

Module: email.mime.image

A subclass of *MIMENonMultipart*, the *MIMEImage* class is used to create MIME message objects of major type *image*. *_imagedata* is a string containing the raw image data. If this data can be decoded by the standard Python module *imghdr*, then the subtype will be automatically included in the *Content-Type* header. Otherwise you can explicitly specify the image subtype via the *_subtype* argument. If the minor type could not be guessed and *_subtype* was not given, then *TypeError* is raised.

Optional *_encoder* is a callable (i.e. function) which will perform the actual encoding of the image data for transport. This callable takes one argument, which is the *MIMEImage* instance. It should use *get_payload()* and *set_payload()* to change the payload to encoded form. It should also add any *Content-Transfer-Encoding* or other headers to the message object as necessary. The default encoding is base64. See the *email.encoders* module for a list of the built-in encoders.

Optional *policy* argument defaults to *compat32*.

_params are passed straight through to the *MIMEBase* constructor.

Changed in version 3.6: Added *policy* keyword-only parameter.

class email.mime.message.MIMEMessage(*_msg*, *_subtype='rfc822'*, ***, *policy=compat32*)

Module: email.mime.message

A subclass of *MIMENonMultipart*, the *MIMEMessage* class is used to create MIME objects of main type *message*. *_msg* is used as the payload, and must be an instance of class *Message* (or a subclass thereof), otherwise a *TypeError* is raised.

Optional *_subtype* sets the subtype of the message; it defaults to *rfc822*.

Optional *policy* argument defaults to *compat32*.

Changed in version 3.6: Added *policy* keyword-only parameter.

class email.mime.text.MIMEText(*_text*, *_subtype='plain'*, *_charset=None*, ***, *policy=compat32*)

Module: email.mime.text

A subclass of *MIMENonMultipart*, the *MIMEText* class is used to create MIME objects of major type *text*. *_text* is the string for the payload. *_subtype* is the minor type and defaults to *plain*. *_charset* is the character set of the text and is passed as an argument to the *MIMENonMultipart* constructor; it defaults to `us-ascii` if the string contains only `ascii` code points, and `utf-8` otherwise. The *_charset* parameter accepts either a string or a *Charset* instance.

Unless the *_charset* argument is explicitly set to `None`, the MIMEText object created will have both a *Content-Type* header with a `charset` parameter, and a *Content-Transfer-Encoding* header. This means that a subsequent `set_payload` call will not result in an encoded payload, even if a charset is passed in the `set_payload` command. You can "reset" this behavior by deleting the `Content-Transfer-Encoding` header, after which a `set_payload` call will automatically encode the new payload (and add a new *Content-Transfer-Encoding* header).

Optional *policy* argument defaults to *compat32*.

Changed in version 3.5: *_charset* also accepts *Charset* instances.

Changed in version 3.6: Added *policy* keyword-only parameter.

20.1.11 email.header: Internationalized headers

Source code: Lib/email/header.py

This module is part of the legacy (Compat32) email API. In the current API encoding and decoding of headers is handled transparently by the dictionary-like API of the *EmailMessage* class. In addition to uses in legacy code, this module can be useful in applications that need to completely control the character sets used when encoding headers.

The remaining text in this section is the original documentation of the module.

RFC 2822 is the base standard that describes the format of email messages. It derives from the older **RFC 822** standard which came into widespread use at a time when most email was composed of ASCII characters only. **RFC 2822** is a specification written assuming email contains only 7-bit ASCII characters.

Of course, as email has been deployed worldwide, it has become internationalized, such that language specific character sets can now be used in email messages. The base standard still requires email messages to be transferred using only 7-bit ASCII characters, so a slew of RFCs have been written describing how to encode email containing non-ASCII characters into **RFC 2822**-compliant format. These RFCs include **RFC 2045**, **RFC 2046**, **RFC 2047**, and **RFC 2231**. The *email* package supports these standards in its *email.header* and *email.charset* modules.

If you want to include non-ASCII characters in your email headers, say in the *Subject* or *To* fields, you should use the *Header* class and assign the field in the *Message* object to an instance of *Header* instead of using a string for the header value. Import the *Header* class from the *email.header* module. For example:

```
>>> from email.message import Message
>>> from email.header import Header
>>> msg = Message()
>>> h = Header('p\xf6stal', 'iso-8859-1')
>>> msg['Subject'] = h
>>> msg.as_string()
'Subject: =?iso-8859-1?q?p=F6stal?=\n\n'
```

Notice here how we wanted the *Subject* field to contain a non-ASCII character? We did this by creating a *Header* instance and passing in the character set that the byte string was encoded in. When the subsequent *Message* instance was flattened, the *Subject* field was properly **RFC 2047** encoded. MIME-aware mail readers would show this header using the embedded ISO-8859-1 character.

Here is the *Header* class description:

class email.header.Header(*s=None*, *charset=None*, *maxlinelen=None*, *header_name=None*, *continuation_ws=' '*, *errors='strict'*)

Create a MIME-compliant header that can contain strings in different character sets.

Optional *s* is the initial header value. If None (the default), the initial header value is not set. You can later append to the header with *append()* method calls. *s* may be an instance of *bytes* or *str*, but see the *append()* documentation for semantics.

Optional *charset* serves two purposes: it has the same meaning as the *charset* argument to the *append()* method. It also sets the default character set for all subsequent *append()* calls that omit the *charset* argument. If *charset* is not provided in the constructor (the default), the us-ascii character set is used both as *s*'s initial charset and as the default for subsequent *append()* calls.

The maximum line length can be specified explicitly via *maxlinelen*. For splitting the first line to a shorter value (to account for the field header which isn't included in *s*, e.g. *Subject*) pass in the name of the field in *header_name*. The default *maxlinelen* is 76, and the default value for *header_name* is None, meaning it is not taken into account for the first line of a long, split header.

Optional *continuation_ws* must be **RFC 2822**-compliant folding whitespace, and is usually either a space or a hard tab character. This character will be prepended to continuation lines. *continuation_ws* defaults to a single space character.

Optional *errors* is passed straight through to the *append()* method.

append(*s*, *charset=None*, *errors='strict'*)
Append the string *s* to the MIME header.

Optional *charset*, if given, should be a *Charset* instance (see *email.charset*) or the name of a character set, which will be converted to a *Charset* instance. A value of `None` (the default) means that the *charset* given in the constructor is used.

s may be an instance of *bytes* or *str*. If it is an instance of *bytes*, then *charset* is the encoding of that byte string, and a *UnicodeError* will be raised if the string cannot be decoded with that character set.

If *s* is an instance of *str*, then *charset* is a hint specifying the character set of the characters in the string.

In either case, when producing an **RFC 2822**-compliant header using **RFC 2047** rules, the string will be encoded using the output codec of the charset. If the string cannot be encoded using the output codec, a UnicodeError will be raised.

Optional *errors* is passed as the errors argument to the decode call if *s* is a byte string.

encode(*splitchars=';, \t'*, *maxlinelen=None*, *linesep='\n'*)
Encode a message header into an RFC-compliant format, possibly wrapping long lines and encapsulating non-ASCII parts in base64 or quoted-printable encodings.

Optional *splitchars* is a string containing characters which should be given extra weight by the splitting algorithm during normal header wrapping. This is in very rough support of **RFC 2822**'s 'higher level syntactic breaks': split points preceded by a splitchar are preferred during line splitting, with the characters preferred in the order in which they appear in the string. Space and tab may be included in the string to indicate whether preference should be given to one over the other as a split point when other split chars do not appear in the line being split. Splitchars does not affect **RFC 2047** encoded lines.

maxlinelen, if given, overrides the instance's value for the maximum line length.

linesep specifies the characters used to separate the lines of the folded header. It defaults to the most useful value for Python application code (`\n`), but `\r\n` can be specified in order to produce headers with RFC-compliant line separators.

Changed in version 3.2: Added the *linesep* argument.

The *Header* class also provides a number of methods to support standard operators and built-in functions.

__str__()
Returns an approximation of the *Header* as a string, using an unlimited line length. All pieces are converted to unicode using the specified encoding and joined together appropriately. Any pieces with a charset of `'unknown-8bit'` are decoded as ASCII using the `'replace'` error handler.

Changed in version 3.2: Added handling for the `'unknown-8bit'` charset.

__eq__(*other*)
This method allows you to compare two *Header* instances for equality.

__ne__(*other*)
This method allows you to compare two *Header* instances for inequality.

The *email.header* module also provides the following convenient functions.

email.header.decode_header(*header*)
Decode a message header value without converting the character set. The header value is in *header*.

This function returns a list of `(decoded_string, charset)` pairs containing each of the decoded parts of the header. *charset* is `None` for non-encoded parts of the header, otherwise a lower case string containing the name of the character set specified in the encoded string.

Here's an example:

```
>>> from email.header import decode_header
>>> decode_header('=?iso-8859-1?q?p=F6stal?=')
[(b'p\xf6stal', 'iso-8859-1')]
```

email.header.make_header(*decoded_seq*, *maxlinelen=None*, *header_name=None*, *continuation_ws=' '*)
Create a *Header* instance from a sequence of pairs as returned by *decode_header()*.

decode_header() takes a header value string and returns a sequence of pairs of the format `(decoded_string, charset)` where *charset* is the name of the character set.

This function takes one of those sequence of pairs and returns a *Header* instance. Optional *maxlinelen*, *header_name*, and *continuation_ws* are as in the *Header* constructor.

20.1.12 email.charset: Representing character sets

Source code: Lib/email/charset.py

This module is part of the legacy (`Compat32`) email API. In the new API only the aliases table is used.

The remaining text in this section is the original documentation of the module.

This module provides a class *Charset* for representing character sets and character set conversions in email messages, as well as a character set registry and several convenience methods for manipulating this registry. Instances of *Charset* are used in several other modules within the *email* package.

Import this class from the *email.charset* module.

class email.charset.Charset(*input_charset=DEFAULT_CHARSET*)
Map character sets to their email properties.

This class provides information about the requirements imposed on email for a specific character set. It also provides convenience routines for converting between character sets, given the availability of the applicable codecs. Given a character set, it will do its best to provide information on how to use that character set in an email message in an RFC-compliant way.

Certain character sets must be encoded with quoted-printable or base64 when used in email headers or bodies. Certain character sets must be converted outright, and are not allowed in email.

Optional *input_charset* is as described below; it is always coerced to lower case. After being alias normalized it is also used as a lookup into the registry of character sets to find out the header encoding, body encoding, and output conversion codec to be used for the character set. For example, if *input_charset* is `iso-8859-1`, then headers and bodies will be encoded using quoted-printable and no output conversion codec is necessary. If *input_charset* is `euc-jp`, then headers will be encoded with base64, bodies will not be encoded, but output text will be converted from the `euc-jp` character set to the `iso-2022-jp` character set.

Charset instances have the following data attributes:

input_charset
The initial character set specified. Common aliases are converted to their *official* email names (e.g. `latin_1` is converted to `iso-8859-1`). Defaults to 7-bit `us-ascii`.

header_encoding
If the character set must be encoded before it can be used in an email header, this attribute will be set to `Charset.QP` (for quoted-printable), `Charset.BASE64` (for base64 encoding), or `Charset.SHORTEST` for the shortest of QP or BASE64 encoding. Otherwise, it will be `None`.

body_encoding
Same as *header_encoding*, but describes the encoding for the mail message's body, which indeed may be different than the header encoding. `Charset.SHORTEST` is not allowed for *body_encoding*.

output_charset
Some character sets must be converted before they can be used in email headers or bodies. If the *input_charset* is one of them, this attribute will contain the name of the character set output will be converted to. Otherwise, it will be `None`.

input_codec
The name of the Python codec used to convert the *input_charset* to Unicode. If no conversion codec is necessary, this attribute will be `None`.

output_codec
The name of the Python codec used to convert Unicode to the *output_charset*. If no conversion codec is necessary, this attribute will have the same value as the *input_codec*.

Charset instances also have the following methods:

get_body_encoding()
Return the content transfer encoding used for body encoding.

This is either the string `quoted-printable` or `base64` depending on the encoding used, or it is a function, in which case you should call the function with a single argument, the Message object being encoded. The function should then set the *Content-Transfer-Encoding* header itself to whatever is appropriate.

Returns the string `quoted-printable` if *body_encoding* is `QP`, returns the string `base64` if *body_encoding* is `BASE64`, and returns the string `7bit` otherwise.

get_output_charset()
Return the output character set.

This is the *output_charset* attribute if that is not `None`, otherwise it is *input_charset*.

header_encode(*string***)**
Header-encode the string *string*.

The type of encoding (base64 or quoted-printable) will be based on the *header_encoding* attribute.

header_encode_lines(*string*, *maxlengths***)**
Header-encode a *string* by converting it first to bytes.

This is similar to *header_encode()* except that the string is fit into maximum line lengths as given by the argument *maxlengths*, which must be an iterator: each element returned from this iterator will provide the next maximum line length.

body_encode(*string***)**
Body-encode the string *string*.

The type of encoding (base64 or quoted-printable) will be based on the *body_encoding* attribute.

The *Charset* class also provides a number of methods to support standard operations and built-in functions.

__str__()
Returns *input_charset* as a string coerced to lower case. `__repr__()` is an alias for *__str__()*.

__eq__(*other***)**
This method allows you to compare two *Charset* instances for equality.

`__ne__`(*other*)
This method allows you to compare two *Charset* instances for inequality.

The *email.charset* module also provides the following functions for adding new entries to the global character set, alias, and codec registries:

`email.charset.add_charset`(*charset*, *header_enc=None*, *body_enc=None*, *output_charset=None*)
Add character properties to the global registry.

charset is the input character set, and must be the canonical name of a character set.

Optional *header_enc* and *body_enc* is either `Charset.QP` for quoted-printable, `Charset.BASE64` for base64 encoding, `Charset.SHORTEST` for the shortest of quoted-printable or base64 encoding, or `None` for no encoding. `SHORTEST` is only valid for *header_enc*. The default is `None` for no encoding.

Optional *output_charset* is the character set that the output should be in. Conversions will proceed from input charset, to Unicode, to the output charset when the method `Charset.convert()` is called. The default is to output in the same character set as the input.

Both *input_charset* and *output_charset* must have Unicode codec entries in the module's character set-to-codec mapping; use *add_codec()* to add codecs the module does not know about. See the *codecs* module's documentation for more information.

The global character set registry is kept in the module global dictionary `CHARSETS`.

`email.charset.add_alias`(*alias*, *canonical*)
Add a character set alias. *alias* is the alias name, e.g. `latin-1`. *canonical* is the character set's canonical name, e.g. `iso-8859-1`.

The global charset alias registry is kept in the module global dictionary `ALIASES`.

`email.charset.add_codec`(*charset*, *codecname*)
Add a codec that map characters in the given character set to and from Unicode.

charset is the canonical name of a character set. *codecname* is the name of a Python codec, as appropriate for the second argument to the *str*'s *encode()* method.

20.1.13 `email.encoders`: Encoders

Source code: Lib/email/encoders.py

This module is part of the legacy (`Compat32`) email API. In the new API the functionality is provided by the *cte* parameter of the *set_content()* method.

The remaining text in this section is the original documentation of the module.

When creating *Message* objects from scratch, you often need to encode the payloads for transport through compliant mail servers. This is especially true for *image/** and *text/** type messages containing binary data.

The *email* package provides some convenient encodings in its `encoders` module. These encoders are actually used by the *MIMEAudio* and *MIMEImage* class constructors to provide default encodings. All encoder functions take exactly one argument, the message object to encode. They usually extract the payload, encode it, and reset the payload to this newly encoded value. They should also set the *Content-Transfer-Encoding* header as appropriate.

Note that these functions are not meaningful for a multipart message. They must be applied to individual subparts instead, and will raise a *TypeError* if passed a message whose type is multipart.

Here are the encoding functions provided:

email.encoders.encode_quopri(*msg*)
: Encodes the payload into quoted-printable form and sets the *Content-Transfer-Encoding* header to `quoted-printable`[1]. This is a good encoding to use when most of your payload is normal printable data, but contains a few unprintable characters.

email.encoders.encode_base64(*msg*)
: Encodes the payload into base64 form and sets the *Content-Transfer-Encoding* header to `base64`. This is a good encoding to use when most of your payload is unprintable data since it is a more compact form than quoted-printable. The drawback of base64 encoding is that it renders the text non-human readable.

email.encoders.encode_7or8bit(*msg*)
: This doesn't actually modify the message's payload, but it does set the *Content-Transfer-Encoding* header to either `7bit` or `8bit` as appropriate, based on the payload data.

email.encoders.encode_noop(*msg*)
: This does nothing; it doesn't even set the *Content-Transfer-Encoding* header.

20.1.14 email.utils: Miscellaneous utilities

Source code: Lib/email/utils.py

There are a couple of useful utilities provided in the *email.utils* module:

email.utils.localtime(*dt=None*)
: Return local time as an aware datetime object. If called without arguments, return current time. Otherwise *dt* argument should be a *datetime* instance, and it is converted to the local time zone according to the system time zone database. If *dt* is naive (that is, `dt.tzinfo` is `None`), it is assumed to be in local time. In this case, a positive or zero value for *isdst* causes `localtime` to presume initially that summer time (for example, Daylight Saving Time) is or is not (respectively) in effect for the specified time. A negative value for *isdst* causes the `localtime` to attempt to divine whether summer time is in effect for the specified time.

  New in version 3.3.

email.utils.make_msgid(*idstring=None*, *domain=None*)
: Returns a string suitable for an **RFC 2822**-compliant *Message-ID* header. Optional *idstring* if given, is a string used to strengthen the uniqueness of the message id. Optional *domain* if given provides the portion of the msgid after the '@'. The default is the local hostname. It is not normally necessary to override this default, but may be useful certain cases, such as a constructing distributed system that uses a consistent domain name across multiple hosts.

  Changed in version 3.2: Added the *domain* keyword.

The remaining functions are part of the legacy (`Compat32`) email API. There is no need to directly use these with the new API, since the parsing and formatting they provide is done automatically by the header parsing machinery of the new API.

email.utils.quote(*str*)
: Return a new string with backslashes in *str* replaced by two backslashes, and double quotes replaced by backslash-double quote.

email.utils.unquote(*str*)
: Return a new string which is an *unquoted* version of *str*. If *str* ends and begins with double quotes, they are stripped off. Likewise if *str* ends and begins with angle brackets, they are stripped off.

[1] Note that encoding with *encode_quopri()* also encodes all tabs and space characters in the data.

email.utils.**parseaddr**(*address*)
Parse address – which should be the value of some address-containing field such as *To* or *Cc* – into its constituent *realname* and *email address* parts. Returns a tuple of that information, unless the parse fails, in which case a 2-tuple of `('', '')` is returned.

email.utils.**formataddr**(*pair*, *charset='utf-8'*)
The inverse of *parseaddr()*, this takes a 2-tuple of the form `(realname, email_address)` and returns the string value suitable for a *To* or *Cc* header. If the first element of *pair* is false, then the second element is returned unmodified.

Optional *charset* is the character set that will be used in the **RFC 2047** encoding of the `realname` if the `realname` contains non-ASCII characters. Can be an instance of *str* or a *Charset*. Defaults to `utf-8`.

Changed in version 3.3: Added the *charset* option.

email.utils.**getaddresses**(*fieldvalues*)
This method returns a list of 2-tuples of the form returned by `parseaddr()`. *fieldvalues* is a sequence of header field values as might be returned by *Message.get_all*. Here's a simple example that gets all the recipients of a message:

```
from email.utils import getaddresses

tos = msg.get_all('to', [])
ccs = msg.get_all('cc', [])
resent_tos = msg.get_all('resent-to', [])
resent_ccs = msg.get_all('resent-cc', [])
all_recipients = getaddresses(tos + ccs + resent_tos + resent_ccs)
```

email.utils.**parsedate**(*date*)
Attempts to parse a date according to the rules in **RFC 2822**. however, some mailers don't follow that format as specified, so *parsedate()* tries to guess correctly in such cases. *date* is a string containing an **RFC 2822** date, such as `"Mon, 20 Nov 1995 19:12:08 -0500"`. If it succeeds in parsing the date, *parsedate()* returns a 9-tuple that can be passed directly to *time.mktime()*; otherwise `None` will be returned. Note that indexes 6, 7, and 8 of the result tuple are not usable.

email.utils.**parsedate_tz**(*date*)
Performs the same function as *parsedate()*, but returns either `None` or a 10-tuple; the first 9 elements make up a tuple that can be passed directly to *time.mktime()*, and the tenth is the offset of the date's timezone from UTC (which is the official term for Greenwich Mean Time)[1]. If the input string has no timezone, the last element of the tuple returned is `None`. Note that indexes 6, 7, and 8 of the result tuple are not usable.

email.utils.**parsedate_to_datetime**(*date*)
The inverse of *format_datetime()*. Performs the same function as *parsedate()*, but on success returns a *datetime*. If the input date has a timezone of `-0000`, the `datetime` will be a naive `datetime`, and if the date is conforming to the RFCs it will represent a time in UTC but with no indication of the actual source timezone of the message the date comes from. If the input date has any other valid timezone offset, the `datetime` will be an aware `datetime` with the corresponding a *timezone tzinfo*.

New in version 3.3.

email.utils.**mktime_tz**(*tuple*)
Turn a 10-tuple as returned by *parsedate_tz()* into a UTC timestamp (seconds since the Epoch). If the timezone item in the tuple is `None`, assume local time.

email.utils.**formatdate**(*timeval=None*, *localtime=False*, *usegmt=False*)
Returns a date string as per **RFC 2822**, e.g.:

[1] Note that the sign of the timezone offset is the opposite of the sign of the `time.timezone` variable for the same timezone; the latter variable follows the POSIX standard while this module follows **RFC 2822**.

```
Fri, 09 Nov 2001 01:08:47 -0000
```

Optional *timeval* if given is a floating point time value as accepted by *time.gmtime()* and *time.localtime()*, otherwise the current time is used.

Optional *localtime* is a flag that when `True`, interprets *timeval*, and returns a date relative to the local timezone instead of UTC, properly taking daylight savings time into account. The default is `False` meaning UTC is used.

Optional *usegmt* is a flag that when `True`, outputs a date string with the timezone as an ascii string `GMT`, rather than a numeric `-0000`. This is needed for some protocols (such as HTTP). This only applies when *localtime* is `False`. The default is `False`.

`email.utils.format_datetime`(*dt*, *usegmt=False*)
Like `formatdate`, but the input is a *datetime* instance. If it is a naive datetime, it is assumed to be "UTC with no information about the source timezone", and the conventional `-0000` is used for the timezone. If it is an aware `datetime`, then the numeric timezone offset is used. If it is an aware timezone with offset zero, then *usegmt* may be set to `True`, in which case the string `GMT` is used instead of the numeric timezone offset. This provides a way to generate standards conformant HTTP date headers.

New in version 3.3.

`email.utils.decode_rfc2231`(*s*)
Decode the string *s* according to **RFC 2231**.

`email.utils.encode_rfc2231`(*s*, *charset=None*, *language=None*)
Encode the string *s* according to **RFC 2231**. Optional *charset* and *language*, if given is the character set name and language name to use. If neither is given, *s* is returned as-is. If *charset* is given but *language* is not, the string is encoded using the empty string for *language*.

`email.utils.collapse_rfc2231_value`(*value*, *errors='replace'*, *fallback_charset='us-ascii'*)
When a header parameter is encoded in **RFC 2231** format, *Message.get_param* may return a 3-tuple containing the character set, language, and value. *collapse_rfc2231_value()* turns this into a unicode string. Optional *errors* is passed to the *errors* argument of *str*'s *encode()* method; it defaults to `'replace'`. Optional *fallback_charset* specifies the character set to use if the one in the **RFC 2231** header is not known by Python; it defaults to `'us-ascii'`.

For convenience, if the *value* passed to *collapse_rfc2231_value()* is not a tuple, it should be a string and it is returned unquoted.

`email.utils.decode_params`(*params*)
Decode parameters list according to **RFC 2231**. *params* is a sequence of 2-tuples containing elements of the form `(content-type, string-value)`.

20.1.15 `email.iterators`: Iterators

Source code: Lib/email/iterators.py

Iterating over a message object tree is fairly easy with the *Message.walk* method. The *email.iterators* module provides some useful higher level iterations over message object trees.

`email.iterators.body_line_iterator`(*msg*, *decode=False*)
This iterates over all the payloads in all the subparts of *msg*, returning the string payloads line-by-line. It skips over all the subpart headers, and it skips over any subpart with a payload that isn't a Python string. This is somewhat equivalent to reading the flat text representation of the message from a file using *readline()*, skipping over all the intervening headers.

Optional *decode* is passed through to *Message.get_payload*.

email.iterators.**typed_subpart_iterator**(*msg*, *maintype='text'*, *subtype=None*)

This iterates over all the subparts of *msg*, returning only those subparts that match the MIME type specified by *maintype* and *subtype*.

Note that *subtype* is optional; if omitted, then subpart MIME type matching is done only with the main type. *maintype* is optional too; it defaults to ***text***.

Thus, by default *typed_subpart_iterator()* returns each subpart that has a MIME type of ***text/***.

The following function has been added as a useful debugging tool. It should *not* be considered part of the supported public interface for the package.

email.iterators.**_structure**(*msg*, *fp=None*, *level=0*, *include_default=False*)

Prints an indented representation of the content types of the message object structure. For example:

```
>>> msg = email.message_from_file(somefile)
>>> _structure(msg)
multipart/mixed
    text/plain
    text/plain
    multipart/digest
        message/rfc822
            text/plain
        message/rfc822
            text/plain
        message/rfc822
            text/plain
        message/rfc822
            text/plain
        message/rfc822
            text/plain
    text/plain
```

Optional *fp* is a file-like object to print the output to. It must be suitable for Python's *print()* function. *level* is used internally. *include_default*, if true, prints the default type as well.

20.2 json — JSON encoder and decoder

Source code: Lib/json/__init__.py

JSON (JavaScript Object Notation), specified by **RFC 7159** (which obsoletes **RFC 4627**) and by ECMA-404, is a lightweight data interchange format inspired by JavaScript object literal syntax (although it is not a strict subset of JavaScript[1]).

[1] As noted in the errata for RFC 7159, JSON permits literal U+2028 (LINE SEPARATOR) and U+2029 (PARAGRAPH SEPARATOR) characters in strings, whereas JavaScript (as of ECMAScript Edition 5.1) does not.

json exposes an API familiar to users of the standard library *marshal* and *pickle* modules.

Encoding basic Python object hierarchies:

```
>>> import json
>>> json.dumps(['foo', {'bar': ('baz', None, 1.0, 2)}])
'["foo", {"bar": ["baz", null, 1.0, 2]}]'
>>> print(json.dumps("\"foo\bar"))
"\"foo\bar"
>>> print(json.dumps('\u1234'))
"\u1234"
>>> print(json.dumps('\\'))
"\\"
>>> print(json.dumps({"c": 0, "b": 0, "a": 0}, sort_keys=True))
{"a": 0, "b": 0, "c": 0}
>>> from io import StringIO
>>> io = StringIO()
>>> json.dump(['streaming API'], io)
>>> io.getvalue()
'["streaming API"]'
```

Compact encoding:

```
>>> import json
>>> json.dumps([1, 2, 3, {'4': 5, '6': 7}], separators=(',', ':'))
'[1,2,3,{"4":5,"6":7}]'
```

Pretty printing:

```
>>> import json
>>> print(json.dumps({'4': 5, '6': 7}, sort_keys=True, indent=4))
{
    "4": 5,
    "6": 7
}
```

Decoding JSON:

```
>>> import json
>>> json.loads('["foo", {"bar":["baz", null, 1.0, 2]}]')
['foo', {'bar': ['baz', None, 1.0, 2]}]
>>> json.loads('"\\"foo\\bar"')
'"foo\x08ar'
>>> from io import StringIO
>>> io = StringIO('["streaming API"]')
>>> json.load(io)
['streaming API']
```

Specializing JSON object decoding:

```
>>> import json
>>> def as_complex(dct):
...     if '__complex__' in dct:
...         return complex(dct['real'], dct['imag'])
...     return dct
...
>>> json.loads('{"__complex__": true, "real": 1, "imag": 2}',
...     object_hook=as_complex)
(1+2j)
```

(continues on next page)

(continued from previous page)

```
>>> import decimal
>>> json.loads('1.1', parse_float=decimal.Decimal)
Decimal('1.1')
```

Extending *JSONEncoder*:

```
>>> import json
>>> class ComplexEncoder(json.JSONEncoder):
...     def default(self, obj):
...         if isinstance(obj, complex):
...             return [obj.real, obj.imag]
...         # Let the base class default method raise the TypeError
...         return json.JSONEncoder.default(self, obj)
...
>>> json.dumps(2 + 1j, cls=ComplexEncoder)
'[2.0, 1.0]'
>>> ComplexEncoder().encode(2 + 1j)
'[2.0, 1.0]'
>>> list(ComplexEncoder().iterencode(2 + 1j))
['[2.0', ', 1.0', ']']
```

Using *json.tool* from the shell to validate and pretty-print:

```
$ echo '{"json":"obj"}' | python -m json.tool
{
    "json": "obj"
}
$ echo '{1.2:3.4}' | python -m json.tool
Expecting property name enclosed in double quotes: line 1 column 2 (char 1)
```

See *Command Line Interface* for detailed documentation.

Note: JSON is a subset of YAML 1.2. The JSON produced by this module's default settings (in particular, the default *separators* value) is also a subset of YAML 1.0 and 1.1. This module can thus also be used as a YAML serializer.

20.2.1 Basic Usage

`json.dump`(*obj*, *fp*, ***, *skipkeys=False*, *ensure_ascii=True*, *check_circular=True*, *allow_nan=True*, *cls=None*, *indent=None*, *separators=None*, *default=None*, *sort_keys=False*, ***kw*)

Serialize *obj* as a JSON formatted stream to *fp* (a `.write()`-supporting *file-like object*) using this *conversion table*.

If *skipkeys* is true (default: `False`), then dict keys that are not of a basic type (*str*, *int*, *float*, *bool*, `None`) will be skipped instead of raising a *TypeError*.

The *json* module always produces *str* objects, not *bytes* objects. Therefore, `fp.write()` must support *str* input.

If *ensure_ascii* is true (the default), the output is guaranteed to have all incoming non-ASCII characters escaped. If *ensure_ascii* is false, these characters will be output as-is.

If *check_circular* is false (default: `True`), then the circular reference check for container types will be skipped and a circular reference will result in an *OverflowError* (or worse).

If *allow_nan* is false (default: `True`), then it will be a *ValueError* to serialize out of range *float* values (`nan`, `inf`, `-inf`) in strict compliance of the JSON specification. If *allow_nan* is true, their JavaScript equivalents (`NaN`, `Infinity`, `-Infinity`) will be used.

If *indent* is a non-negative integer or string, then JSON array elements and object members will be pretty-printed with that indent level. An indent level of 0, negative, or `""` will only insert newlines. `None` (the default) selects the most compact representation. Using a positive integer indent indents that many spaces per level. If *indent* is a string (such as `"\t"`), that string is used to indent each level.

Changed in version 3.2: Allow strings for *indent* in addition to integers.

If specified, *separators* should be an `(item_separator, key_separator)` tuple. The default is `(', ', ': ')` if *indent* is `None` and `(',', ': ')` otherwise. To get the most compact JSON representation, you should specify `(',', ':')` to eliminate whitespace.

Changed in version 3.4: Use `(',', ': ')` as default if *indent* is not `None`.

If specified, *default* should be a function that gets called for objects that can't otherwise be serialized. It should return a JSON encodable version of the object or raise a *TypeError*. If not specified, *TypeError* is raised.

If *sort_keys* is true (default: `False`), then the output of dictionaries will be sorted by key.

To use a custom *JSONEncoder* subclass (e.g. one that overrides the `default()` method to serialize additional types), specify it with the *cls* kwarg; otherwise *JSONEncoder* is used.

Changed in version 3.6: All optional parameters are now *keyword-only*.

`json.dumps`(*obj*, ***, *skipkeys=False*, *ensure_ascii=True*, *check_circular=True*, *allow_nan=True*, *cls=None*, *indent=None*, *separators=None*, *default=None*, *sort_keys=False*, ***kw*)

Serialize *obj* to a JSON formatted *str* using this *conversion table*. The arguments have the same meaning as in *dump()*.

Note: Unlike *pickle* and *marshal*, JSON is not a framed protocol, so trying to serialize multiple objects with repeated calls to *dump()* using the same *fp* will result in an invalid JSON file.

Note: Keys in key/value pairs of JSON are always of the type *str*. When a dictionary is converted into JSON, all the keys of the dictionary are coerced to strings. As a result of this, if a dictionary is converted into JSON and then back into a dictionary, the dictionary may not equal the original one. That is, `loads(dumps(x)) != x` if x has non-string keys.

`json.load`(*fp*, ***, *cls=None*, *object_hook=None*, *parse_float=None*, *parse_int=None*, *parse_constant=None*, *object_pairs_hook=None*, ***kw*)

Deserialize *fp* (a `.read()`-supporting *text file* or *binary file* containing a JSON document) to a Python object using this *conversion table*.

object_hook is an optional function that will be called with the result of any object literal decoded (a *dict*). The return value of *object_hook* will be used instead of the *dict*. This feature can be used to implement custom decoders (e.g. JSON-RPC class hinting).

object_pairs_hook is an optional function that will be called with the result of any object literal decoded with an ordered list of pairs. The return value of *object_pairs_hook* will be used instead of the *dict*. This feature can be used to implement custom decoders. If *object_hook* is also defined, the *object_pairs_hook* takes priority.

Changed in version 3.1: Added support for *object_pairs_hook*.

parse_float, if specified, will be called with the string of every JSON float to be decoded. By default, this is equivalent to `float(num_str)`. This can be used to use another datatype or parser for JSON

floats (e.g. *decimal.Decimal*).

parse_int, if specified, will be called with the string of every JSON int to be decoded. By default, this is equivalent to `int(num_str)`. This can be used to use another datatype or parser for JSON integers (e.g. *float*).

parse_constant, if specified, will be called with one of the following strings: `'-Infinity'`, `'Infinity'`, `'NaN'`. This can be used to raise an exception if invalid JSON numbers are encountered.

Changed in version 3.1: *parse_constant* doesn't get called on 'null', 'true', 'false' anymore.

To use a custom *JSONDecoder* subclass, specify it with the `cls` kwarg; otherwise *JSONDecoder* is used. Additional keyword arguments will be passed to the constructor of the class.

If the data being deserialized is not a valid JSON document, a *JSONDecodeError* will be raised.

Changed in version 3.6: All optional parameters are now *keyword-only*.

Changed in version 3.6: *fp* can now be a *binary file*. The input encoding should be UTF-8, UTF-16 or UTF-32.

`json.loads`(*s*, ***, *encoding=None*, *cls=None*, *object_hook=None*, *parse_float=None*, *parse_int=None*, *parse_constant=None*, *object_pairs_hook=None*, ***kw*)

Deserialize *s* (a *str*, *bytes* or *bytearray* instance containing a JSON document) to a Python object using this *conversion table*.

The other arguments have the same meaning as in *load()*, except *encoding* which is ignored and deprecated.

If the data being deserialized is not a valid JSON document, a *JSONDecodeError* will be raised.

Changed in version 3.6: *s* can now be of type *bytes* or *bytearray*. The input encoding should be UTF-8, UTF-16 or UTF-32.

20.2.2 Encoders and Decoders

`class json.JSONDecoder`(***, *object_hook=None*, *parse_float=None*, *parse_int=None*, *parse_constant=None*, *strict=True*, *object_pairs_hook=None*)

Simple JSON decoder.

Performs the following translations in decoding by default:

JSON	Python
object	dict
array	list
string	str
number (int)	int
number (real)	float
true	True
false	False
null	None

It also understands `NaN`, `Infinity`, and `-Infinity` as their corresponding `float` values, which is outside the JSON spec.

object_hook, if specified, will be called with the result of every JSON object decoded and its return value will be used in place of the given *dict*. This can be used to provide custom deserializations (e.g. to support JSON-RPC class hinting).

object_pairs_hook, if specified will be called with the result of every JSON object decoded with an ordered list of pairs. The return value of *object_pairs_hook* will be used instead of the *dict*. This

feature can be used to implement custom decoders. If *object_hook* is also defined, the *object_pairs_hook* takes priority.

Changed in version 3.1: Added support for *object_pairs_hook*.

parse_float, if specified, will be called with the string of every JSON float to be decoded. By default, this is equivalent to `float(num_str)`. This can be used to use another datatype or parser for JSON floats (e.g. *decimal.Decimal*).

parse_int, if specified, will be called with the string of every JSON int to be decoded. By default, this is equivalent to `int(num_str)`. This can be used to use another datatype or parser for JSON integers (e.g. *float*).

parse_constant, if specified, will be called with one of the following strings: `'-Infinity'`, `'Infinity'`, `'NaN'`. This can be used to raise an exception if invalid JSON numbers are encountered.

If *strict* is false (`True` is the default), then control characters will be allowed inside strings. Control characters in this context are those with character codes in the 0–31 range, including `'\t'` (tab), `'\n'`, `'\r'` and `'\0'`.

If the data being deserialized is not a valid JSON document, a *JSONDecodeError* will be raised.

Changed in version 3.6: All parameters are now *keyword-only*.

`decode(`*s*`)`
Return the Python representation of *s* (a *str* instance containing a JSON document).

JSONDecodeError will be raised if the given JSON document is not valid.

`raw_decode(`*s*`)`
Decode a JSON document from *s* (a *str* beginning with a JSON document) and return a 2-tuple of the Python representation and the index in *s* where the document ended.

This can be used to decode a JSON document from a string that may have extraneous data at the end.

`class json.JSONEncoder(`**, skipkeys=False, ensure_ascii=True, check_circular=True, allow_nan=True, sort_keys=False, indent=None, separators=None, default=None*`)`
Extensible JSON encoder for Python data structures.

Supports the following objects and types by default:

Python	JSON
dict	object
list, tuple	array
str	string
int, float, int- & float-derived Enums	number
True	true
False	false
None	null

Changed in version 3.4: Added support for int- and float-derived Enum classes.

To extend this to recognize other objects, subclass and implement a *default()* method with another method that returns a serializable object for `o` if possible, otherwise it should call the superclass implementation (to raise *TypeError*).

If *skipkeys* is false (the default), then it is a *TypeError* to attempt encoding of keys that are not *str*, *int*, *float* or `None`. If *skipkeys* is true, such items are simply skipped.

If *ensure_ascii* is true (the default), the output is guaranteed to have all incoming non-ASCII characters escaped. If *ensure_ascii* is false, these characters will be output as-is.

If *check_circular* is true (the default), then lists, dicts, and custom encoded objects will be checked for circular references during encoding to prevent an infinite recursion (which would cause an *OverflowError*). Otherwise, no such check takes place.

If *allow_nan* is true (the default), then `NaN`, `Infinity`, and `-Infinity` will be encoded as such. This behavior is not JSON specification compliant, but is consistent with most JavaScript based encoders and decoders. Otherwise, it will be a *ValueError* to encode such floats.

If *sort_keys* is true (default: `False`), then the output of dictionaries will be sorted by key; this is useful for regression tests to ensure that JSON serializations can be compared on a day-to-day basis.

If *indent* is a non-negative integer or string, then JSON array elements and object members will be pretty-printed with that indent level. An indent level of 0, negative, or `""` will only insert newlines. `None` (the default) selects the most compact representation. Using a positive integer indent indents that many spaces per level. If *indent* is a string (such as `"\t"`), that string is used to indent each level.

Changed in version 3.2: Allow strings for *indent* in addition to integers.

If specified, *separators* should be an `(item_separator, key_separator)` tuple. The default is `(', ', ': ')` if *indent* is `None` and `(',', ': ')` otherwise. To get the most compact JSON representation, you should specify `(',', ':')` to eliminate whitespace.

Changed in version 3.4: Use `(',', ': ')` as default if *indent* is not `None`.

If specified, *default* should be a function that gets called for objects that can't otherwise be serialized. It should return a JSON encodable version of the object or raise a *TypeError*. If not specified, *TypeError* is raised.

Changed in version 3.6: All parameters are now *keyword-only*.

default(*o*)

Implement this method in a subclass such that it returns a serializable object for *o*, or calls the base implementation (to raise a *TypeError*).

For example, to support arbitrary iterators, you could implement default like this:

```
def default(self, o):
   try:
       iterable = iter(o)
   except TypeError:
       pass
   else:
       return list(iterable)
   # Let the base class default method raise the TypeError
   return json.JSONEncoder.default(self, o)
```

encode(*o*)

Return a JSON string representation of a Python data structure, *o*. For example:

```
>>> json.JSONEncoder().encode({"foo": ["bar", "baz"]})
'{"foo": ["bar", "baz"]}'
```

iterencode(*o*)

Encode the given object, *o*, and yield each string representation as available. For example:

```
for chunk in json.JSONEncoder().iterencode(bigobject):
    mysocket.write(chunk)
```

20.2.3 Exceptions

exception json.**JSONDecodeError**(*msg*, *doc*, *pos*)
Subclass of *ValueError* with the following additional attributes:

msg
The unformatted error message.

doc
The JSON document being parsed.

pos
The start index of *doc* where parsing failed.

lineno
The line corresponding to *pos*.

colno
The column corresponding to *pos*.

New in version 3.5.

20.2.4 Standard Compliance and Interoperability

The JSON format is specified by **RFC 7159** and by ECMA-404. This section details this module's level of compliance with the RFC. For simplicity, *JSONEncoder* and *JSONDecoder* subclasses, and parameters other than those explicitly mentioned, are not considered.

This module does not comply with the RFC in a strict fashion, implementing some extensions that are valid JavaScript but not valid JSON. In particular:

- Infinite and NaN number values are accepted and output;
- Repeated names within an object are accepted, and only the value of the last name-value pair is used.

Since the RFC permits RFC-compliant parsers to accept input texts that are not RFC-compliant, this module's deserializer is technically RFC-compliant under default settings.

Character Encodings

The RFC requires that JSON be represented using either UTF-8, UTF-16, or UTF-32, with UTF-8 being the recommended default for maximum interoperability.

As permitted, though not required, by the RFC, this module's serializer sets *ensure_ascii=True* by default, thus escaping the output so that the resulting strings only contain ASCII characters.

Other than the *ensure_ascii* parameter, this module is defined strictly in terms of conversion between Python objects and *Unicode strings*, and thus does not otherwise directly address the issue of character encodings.

The RFC prohibits adding a byte order mark (BOM) to the start of a JSON text, and this module's serializer does not add a BOM to its output. The RFC permits, but does not require, JSON deserializers to ignore an initial BOM in their input. This module's deserializer raises a *ValueError* when an initial BOM is present.

The RFC does not explicitly forbid JSON strings which contain byte sequences that don't correspond to valid Unicode characters (e.g. unpaired UTF-16 surrogates), but it does note that they may cause interoperability problems. By default, this module accepts and outputs (when present in the original *str*) code points for such sequences.

Infinite and NaN Number Values

The RFC does not permit the representation of infinite or NaN number values. Despite that, by default, this module accepts and outputs `Infinity`, `-Infinity`, and `NaN` as if they were valid JSON number literal values:

```
>>> # Neither of these calls raises an exception, but the results are not valid JSON
>>> json.dumps(float('-inf'))
'-Infinity'
>>> json.dumps(float('nan'))
'NaN'
>>> # Same when deserializing
>>> json.loads('-Infinity')
-inf
>>> json.loads('NaN')
nan
```

In the serializer, the *allow_nan* parameter can be used to alter this behavior. In the deserializer, the *parse_constant* parameter can be used to alter this behavior.

Repeated Names Within an Object

The RFC specifies that the names within a JSON object should be unique, but does not mandate how repeated names in JSON objects should be handled. By default, this module does not raise an exception; instead, it ignores all but the last name-value pair for a given name:

```
>>> weird_json = '{"x": 1, "x": 2, "x": 3}'
>>> json.loads(weird_json)
{'x': 3}
```

The *object_pairs_hook* parameter can be used to alter this behavior.

Top-level Non-Object, Non-Array Values

The old version of JSON specified by the obsolete **RFC 4627** required that the top-level value of a JSON text must be either a JSON object or array (Python *dict* or *list*), and could not be a JSON null, boolean, number, or string value. **RFC 7159** removed that restriction, and this module does not and has never implemented that restriction in either its serializer or its deserializer.

Regardless, for maximum interoperability, you may wish to voluntarily adhere to the restriction yourself.

Implementation Limitations

Some JSON deserializer implementations may set limits on:

- the size of accepted JSON texts
- the maximum level of nesting of JSON objects and arrays
- the range and precision of JSON numbers
- the content and maximum length of JSON strings

This module does not impose any such limits beyond those of the relevant Python datatypes themselves or the Python interpreter itself.

When serializing to JSON, beware any such limitations in applications that may consume your JSON. In particular, it is common for JSON numbers to be deserialized into IEEE 754 double precision numbers and

thus subject to that representation's range and precision limitations. This is especially relevant when serializing Python *int* values of extremely large magnitude, or when serializing instances of "exotic" numerical types such as *decimal.Decimal*.

20.2.5 Command Line Interface

Source code: Lib/json/tool.py

The *json.tool* module provides a simple command line interface to validate and pretty-print JSON objects.

If the optional `infile` and `outfile` arguments are not specified, *sys.stdin* and *sys.stdout* will be used respectively:

```
$ echo '{"json": "obj"}' | python -m json.tool
{
    "json": "obj"
}
$ echo '{1.2:3.4}' | python -m json.tool
Expecting property name enclosed in double quotes: line 1 column 2 (char 1)
```

Changed in version 3.5: The output is now in the same order as the input. Use the *--sort-keys* option to sort the output of dictionaries alphabetically by key.

Command line options

infile
The JSON file to be validated or pretty-printed:

```
$ python -m json.tool mp_films.json
[
    {
        "title": "And Now for Something Completely Different",
        "year": 1971
    },
    {
        "title": "Monty Python and the Holy Grail",
        "year": 1975
    }
]
```

If *infile* is not specified, read from *sys.stdin*.

outfile
Write the output of the *infile* to the given *outfile*. Otherwise, write it to *sys.stdout*.

--sort-keys
Sort the output of dictionaries alphabetically by key.

New in version 3.5.

-h, --help
Show the help message.

20.3 mailcap — Mailcap file handling

Source code: Lib/mailcap.py

Mailcap files are used to configure how MIME-aware applications such as mail readers and Web browsers react to files with different MIME types. (The name "mailcap" is derived from the phrase "mail capability".) For example, a mailcap file might contain a line like `video/mpeg; xmpeg %s`. Then, if the user encounters an email message or Web document with the MIME type *video/mpeg*, `%s` will be replaced by a filename (usually one belonging to a temporary file) and the **xmpeg** program can be automatically started to view the file.

The mailcap format is documented in **RFC 1524**, "A User Agent Configuration Mechanism For Multimedia Mail Format Information," but is not an Internet standard. However, mailcap files are supported on most Unix systems.

`mailcap.findmatch`(*caps*, *MIMEtype*, *key='view'*, *filename='/dev/null'*, *plist=[]*)

Return a 2-tuple; the first element is a string containing the command line to be executed (which can be passed to *os.system()*), and the second element is the mailcap entry for a given MIME type. If no matching MIME type can be found, `(None, None)` is returned.

key is the name of the field desired, which represents the type of activity to be performed; the default value is 'view', since in the most common case you simply want to view the body of the MIME-typed data. Other possible values might be 'compose' and 'edit', if you wanted to create a new body of the given MIME type or alter the existing body data. See **RFC 1524** for a complete list of these fields.

filename is the filename to be substituted for `%s` in the command line; the default value is `'/dev/null'` which is almost certainly not what you want, so usually you'll override it by specifying a filename.

plist can be a list containing named parameters; the default value is simply an empty list. Each entry in the list must be a string containing the parameter name, an equals sign (`'='`), and the parameter's value. Mailcap entries can contain named parameters like `%{foo}`, which will be replaced by the value of the parameter named 'foo'. For example, if the command line `showpartial %{id} %{number} %{total}` was in a mailcap file, and *plist* was set to `['id=1', 'number=2', 'total=3']`, the resulting command line would be `'showpartial 1 2 3'`.

In a mailcap file, the "test" field can optionally be specified to test some external condition (such as the machine architecture, or the window system in use) to determine whether or not the mailcap line applies. *findmatch()* will automatically check such conditions and skip the entry if the check fails.

`mailcap.getcaps`()

Returns a dictionary mapping MIME types to a list of mailcap file entries. This dictionary must be passed to the *findmatch()* function. An entry is stored as a list of dictionaries, but it shouldn't be necessary to know the details of this representation.

The information is derived from all of the mailcap files found on the system. Settings in the user's mailcap file `$HOME/.mailcap` will override settings in the system mailcap files `/etc/mailcap`, `/usr/etc/mailcap`, and `/usr/local/etc/mailcap`.

An example usage:

```
>>> import mailcap
>>> d = mailcap.getcaps()
>>> mailcap.findmatch(d, 'video/mpeg', filename='tmp1223')
('xmpeg tmp1223', {'view': 'xmpeg %s'})
```

20.4 mailbox — Manipulate mailboxes in various formats

Source code: Lib/mailbox.py

This module defines two classes, *Mailbox* and *Message*, for accessing and manipulating on-disk mailboxes and the messages they contain. *Mailbox* offers a dictionary-like mapping from keys to messages. *Message* extends the *email.message* module's *Message* class with format-specific state and behavior. Supported mailbox formats are Maildir, mbox, MH, Babyl, and MMDF.

See also:

Module *email* Represent and manipulate messages.

20.4.1 Mailbox objects

class mailbox.Mailbox

A mailbox, which may be inspected and modified.

The *Mailbox* class defines an interface and is not intended to be instantiated. Instead, format-specific subclasses should inherit from *Mailbox* and your code should instantiate a particular subclass.

The *Mailbox* interface is dictionary-like, with small keys corresponding to messages. Keys are issued by the *Mailbox* instance with which they will be used and are only meaningful to that *Mailbox* instance. A key continues to identify a message even if the corresponding message is modified, such as by replacing it with another message.

Messages may be added to a *Mailbox* instance using the set-like method *add()* and removed using a `del` statement or the set-like methods *remove()* and *discard()*.

Mailbox interface semantics differ from dictionary semantics in some noteworthy ways. Each time a message is requested, a new representation (typically a *Message* instance) is generated based upon the current state of the mailbox. Similarly, when a message is added to a *Mailbox* instance, the provided message representation's contents are copied. In neither case is a reference to the message representation kept by the *Mailbox* instance.

The default *Mailbox* iterator iterates over message representations, not keys as the default dictionary iterator does. Moreover, modification of a mailbox during iteration is safe and well-defined. Messages added to the mailbox after an iterator is created will not be seen by the iterator. Messages removed from the mailbox before the iterator yields them will be silently skipped, though using a key from an iterator may result in a *KeyError* exception if the corresponding message is subsequently removed.

> **Warning:** Be very cautious when modifying mailboxes that might be simultaneously changed by some other process. The safest mailbox format to use for such tasks is Maildir; try to avoid using single-file formats such as mbox for concurrent writing. If you're modifying a mailbox, you *must* lock it by calling the *lock()* and *unlock()* methods *before* reading any messages in the file or making any changes by adding or deleting a message. Failing to lock the mailbox runs the risk of losing messages or corrupting the entire mailbox.

Mailbox instances have the following methods:

add(*message*)

Add *message* to the mailbox and return the key that has been assigned to it.

Parameter *message* may be a *Message* instance, an *email.message.Message* instance, a string, a byte string, or a file-like object (which should be open in binary mode). If *message* is an instance of the appropriate format-specific *Message* subclass (e.g., if it's an *mboxMessage* instance and this

is an *mbox* instance), its format-specific information is used. Otherwise, reasonable defaults for format-specific information are used.

Changed in version 3.2: Support for binary input was added.

remove(*key*)
__delitem__(*key*)
discard(*key*)
Delete the message corresponding to *key* from the mailbox.

If no such message exists, a *KeyError* exception is raised if the method was called as *remove()* or *__delitem__()* but no exception is raised if the method was called as *discard()*. The behavior of *discard()* may be preferred if the underlying mailbox format supports concurrent modification by other processes.

__setitem__(*key*, *message*)
Replace the message corresponding to *key* with *message*. Raise a *KeyError* exception if no message already corresponds to *key*.

As with *add()*, parameter *message* may be a *Message* instance, an *email.message.Message* instance, a string, a byte string, or a file-like object (which should be open in binary mode). If *message* is an instance of the appropriate format-specific *Message* subclass (e.g., if it's an *mboxMessage* instance and this is an *mbox* instance), its format-specific information is used. Otherwise, the format-specific information of the message that currently corresponds to *key* is left unchanged.

iterkeys()
keys()
Return an iterator over all keys if called as *iterkeys()* or return a list of keys if called as *keys()*.

itervalues()
__iter__()
values()
Return an iterator over representations of all messages if called as *itervalues()* or *__iter__()* or return a list of such representations if called as *values()*. The messages are represented as instances of the appropriate format-specific *Message* subclass unless a custom message factory was specified when the *Mailbox* instance was initialized.

Note: The behavior of *__iter__()* is unlike that of dictionaries, which iterate over keys.

---

iteritems()
items()
Return an iterator over (*key*, *message*) pairs, where *key* is a key and *message* is a message representation, if called as *iteritems()* or return a list of such pairs if called as *items()*. The messages are represented as instances of the appropriate format-specific *Message* subclass unless a custom message factory was specified when the *Mailbox* instance was initialized.

get(*key*, *default=None*)
__getitem__(*key*)
Return a representation of the message corresponding to *key*. If no such message exists, *default* is returned if the method was called as *get()* and a *KeyError* exception is raised if the method was called as *__getitem__()*. The message is represented as an instance of the appropriate format-specific *Message* subclass unless a custom message factory was specified when the *Mailbox* instance was initialized.

get_message(*key*)
Return a representation of the message corresponding to *key* as an instance of the appropriate format-specific *Message* subclass, or raise a *KeyError* exception if no such message exists.

get_bytes(*key*)
Return a byte representation of the message corresponding to *key*, or raise a *KeyError* exception if no such message exists.

New in version 3.2.

get_string(*key*)
Return a string representation of the message corresponding to *key*, or raise a *KeyError* exception if no such message exists. The message is processed through *email.message.Message* to convert it to a 7bit clean representation.

get_file(*key*)
Return a file-like representation of the message corresponding to *key*, or raise a *KeyError* exception if no such message exists. The file-like object behaves as if open in binary mode. This file should be closed once it is no longer needed.

Changed in version 3.2: The file object really is a binary file; previously it was incorrectly returned in text mode. Also, the file-like object now supports the context management protocol: you can use a **with** statement to automatically close it.

Note: Unlike other representations of messages, file-like representations are not necessarily independent of the *Mailbox* instance that created them or of the underlying mailbox. More specific documentation is provided by each subclass.

__contains__(*key*)
Return **True** if *key* corresponds to a message, **False** otherwise.

__len__()
Return a count of messages in the mailbox.

clear()
Delete all messages from the mailbox.

pop(*key*, *default=None*)
Return a representation of the message corresponding to *key* and delete the message. If no such message exists, return *default*. The message is represented as an instance of the appropriate format-specific *Message* subclass unless a custom message factory was specified when the *Mailbox* instance was initialized.

popitem()
Return an arbitrary (*key*, *message*) pair, where *key* is a key and *message* is a message representation, and delete the corresponding message. If the mailbox is empty, raise a *KeyError* exception. The message is represented as an instance of the appropriate format-specific *Message* subclass unless a custom message factory was specified when the *Mailbox* instance was initialized.

update(*arg*)
Parameter *arg* should be a *key*-to-*message* mapping or an iterable of (*key*, *message*) pairs. Updates the mailbox so that, for each given *key* and *message*, the message corresponding to *key* is set to *message* as if by using *__setitem__()*. As with *__setitem__()*, each *key* must already correspond to a message in the mailbox or else a *KeyError* exception will be raised, so in general it is incorrect for *arg* to be a *Mailbox* instance.

Note: Unlike with dictionaries, keyword arguments are not supported.

---

flush()
Write any pending changes to the filesystem. For some *Mailbox* subclasses, changes are always

written immediately and *flush()* does nothing, but you should still make a habit of calling this method.

lock()
Acquire an exclusive advisory lock on the mailbox so that other processes know not to modify it. An *ExternalClashError* is raised if the lock is not available. The particular locking mechanisms used depend upon the mailbox format. You should *always* lock the mailbox before making any modifications to its contents.

unlock()
Release the lock on the mailbox, if any.

close()
Flush the mailbox, unlock it if necessary, and close any open files. For some *Mailbox* subclasses, this method does nothing.

Maildir

class mailbox.Maildir(*dirname*, *factory=None*, *create=True*)
A subclass of *Mailbox* for mailboxes in Maildir format. Parameter *factory* is a callable object that accepts a file-like message representation (which behaves as if opened in binary mode) and returns a custom representation. If *factory* is `None`, *MaildirMessage* is used as the default message representation. If *create* is `True`, the mailbox is created if it does not exist.

It is for historical reasons that *dirname* is named as such rather than *path*.

Maildir is a directory-based mailbox format invented for the qmail mail transfer agent and now widely supported by other programs. Messages in a Maildir mailbox are stored in separate files within a common directory structure. This design allows Maildir mailboxes to be accessed and modified by multiple unrelated programs without data corruption, so file locking is unnecessary.

Maildir mailboxes contain three subdirectories, namely: `tmp`, `new`, and `cur`. Messages are created momentarily in the `tmp` subdirectory and then moved to the `new` subdirectory to finalize delivery. A mail user agent may subsequently move the message to the `cur` subdirectory and store information about the state of the message in a special "info" section appended to its file name.

Folders of the style introduced by the Courier mail transfer agent are also supported. Any subdirectory of the main mailbox is considered a folder if `'.'` is the first character in its name. Folder names are represented by *Maildir* without the leading `'.'`. Each folder is itself a Maildir mailbox but should not contain other folders. Instead, a logical nesting is indicated using `'.'` to delimit levels, e.g., "Archived.2005.07".

Note: The Maildir specification requires the use of a colon (`':'`) in certain message file names. However, some operating systems do not permit this character in file names, If you wish to use a Maildir-like format on such an operating system, you should specify another character to use instead. The exclamation point (`'!'`) is a popular choice. For example:

```
import mailbox
mailbox.Maildir.colon = '!'
```

The `colon` attribute may also be set on a per-instance basis.

Maildir instances have all of the methods of *Mailbox* in addition to the following:

list_folders()
Return a list of the names of all folders.

`get_folder`(*folder*)
Return a *Maildir* instance representing the folder whose name is *folder*. A *NoSuchMailboxError* exception is raised if the folder does not exist.

`add_folder`(*folder*)
Create a folder whose name is *folder* and return a *Maildir* instance representing it.

`remove_folder`(*folder*)
Delete the folder whose name is *folder*. If the folder contains any messages, a *NotEmptyError* exception will be raised and the folder will not be deleted.

`clean`()
Delete temporary files from the mailbox that have not been accessed in the last 36 hours. The Maildir specification says that mail-reading programs should do this occasionally.

Some *Mailbox* methods implemented by *Maildir* deserve special remarks:

`add`(*message*)
`__setitem__`(*key*, *message*)
`update`(*arg*)

> **Warning:** These methods generate unique file names based upon the current process ID. When using multiple threads, undetected name clashes may occur and cause corruption of the mailbox unless threads are coordinated to avoid using these methods to manipulate the same mailbox simultaneously.

`flush`()
All changes to Maildir mailboxes are immediately applied, so this method does nothing.

`lock`()
`unlock`()
Maildir mailboxes do not support (or require) locking, so these methods do nothing.

`close`()
Maildir instances do not keep any open files and the underlying mailboxes do not support locking, so this method does nothing.

`get_file`(*key*)
Depending upon the host platform, it may not be possible to modify or remove the underlying message while the returned file remains open.

maildir man page from Courier Another specification of the format. Describes a common extension for supporting folders.

mbox

`class mailbox.mbox`(*path*, *factory=None*, *create=True*)
A subclass of *Mailbox* for mailboxes in mbox format. Parameter *factory* is a callable object that accepts a file-like message representation (which behaves as if opened in binary mode) and returns a custom representation. If *factory* is `None`, *mboxMessage* is used as the default message representation. If *create* is `True`, the mailbox is created if it does not exist.

The mbox format is the classic format for storing mail on Unix systems. All messages in an mbox mailbox are stored in a single file with the beginning of each message indicated by a line whose first five characters are "From ".

Several variations of the mbox format exist to address perceived shortcomings in the original. In the interest of compatibility, *mbox* implements the original format, which is sometimes referred to as *mboxo*. This means that the *Content-Length* header, if present, is ignored and that any occurrences of "From " at the beginning of a line in a message body are transformed to ">From " when storing the message, although occurrences of ">From " are not transformed to "From " when reading the message.

Some *Mailbox* methods implemented by *mbox* deserve special remarks:

`get_file(`*key*`)`
: Using the file after calling `flush()` or `close()` on the *mbox* instance may yield unpredictable results or raise an exception.

`lock()`
`unlock()`
: Three locking mechanisms are used—dot locking and, if available, the `flock()` and `lockf()` system calls.

mbox man page from qmail A specification of the format and its variations.

mbox man page from tin Another specification of the format, with details on locking.

Configuring Netscape Mail on Unix: Why The Content-Length Format is Bad An argument for using the original mbox format rather than a variation.

"mbox" is a family of several mutually incompatible mailbox formats A history of mbox variations.

MH

`class mailbox.MH(`*path*, *factory=None*, *create=True*`)`
: A subclass of *Mailbox* for mailboxes in MH format. Parameter *factory* is a callable object that accepts a file-like message representation (which behaves as if opened in binary mode) and returns a custom representation. If *factory* is `None`, *MHMessage* is used as the default message representation. If *create* is `True`, the mailbox is created if it does not exist.

MH is a directory-based mailbox format invented for the MH Message Handling System, a mail user agent. Each message in an MH mailbox resides in its own file. An MH mailbox may contain other MH mailboxes (called *folders*) in addition to messages. Folders may be nested indefinitely. MH mailboxes also support *sequences*, which are named lists used to logically group messages without moving them to sub-folders. Sequences are defined in a file called `.mh_sequences` in each folder.

The *MH* class manipulates MH mailboxes, but it does not attempt to emulate all of **mh**'s behaviors. In particular, it does not modify and is not affected by the `context` or `.mh_profile` files that are used by **mh** to store its state and configuration.

MH instances have all of the methods of *Mailbox* in addition to the following:

`list_folders()`
: Return a list of the names of all folders.

`get_folder(`*folder*`)`
: Return an *MH* instance representing the folder whose name is *folder*. A *NoSuchMailboxError* exception is raised if the folder does not exist.

`add_folder(`*folder*`)`
: Create a folder whose name is *folder* and return an *MH* instance representing it.

remove_folder(*folder*)
Delete the folder whose name is *folder*. If the folder contains any messages, a *NotEmptyError* exception will be raised and the folder will not be deleted.

get_sequences()
Return a dictionary of sequence names mapped to key lists. If there are no sequences, the empty dictionary is returned.

set_sequences(*sequences*)
Re-define the sequences that exist in the mailbox based upon *sequences*, a dictionary of names mapped to key lists, like returned by *get_sequences()*.

pack()
Rename messages in the mailbox as necessary to eliminate gaps in numbering. Entries in the sequences list are updated correspondingly.

Note: Already-issued keys are invalidated by this operation and should not be subsequently used.

Some *Mailbox* methods implemented by *MH* deserve special remarks:

remove(*key*)
__delitem__(*key*)
discard(*key*)
These methods immediately delete the message. The MH convention of marking a message for deletion by prepending a comma to its name is not used.

lock()
unlock()
Three locking mechanisms are used—dot locking and, if available, the `flock()` and `lockf()` system calls. For MH mailboxes, locking the mailbox means locking the `.mh_sequences` file and, only for the duration of any operations that affect them, locking individual message files.

get_file(*key*)
Depending upon the host platform, it may not be possible to remove the underlying message while the returned file remains open.

flush()
All changes to MH mailboxes are immediately applied, so this method does nothing.

close()
MH instances do not keep any open files, so this method is equivalent to *unlock()*.

nmh - Message Handling System Home page of **nmh**, an updated version of the original **mh**.

MH & nmh: Email for Users & Programmers A GPL-licensed book on **mh** and **nmh**, with some information on the mailbox format.

Babyl

class mailbox.Babyl(*path*, *factory=None*, *create=True*)
A subclass of *Mailbox* for mailboxes in Babyl format. Parameter *factory* is a callable object that accepts a file-like message representation (which behaves as if opened in binary mode) and returns a custom representation. If *factory* is `None`, *BabylMessage* is used as the default message representation. If *create* is `True`, the mailbox is created if it does not exist.

Babyl is a single-file mailbox format used by the Rmail mail user agent included with Emacs. The beginning of a message is indicated by a line containing the two characters Control-Underscore (`'\037'`)

and Control-L (`'\014'`). The end of a message is indicated by the start of the next message or, in the case of the last message, a line containing a Control-Underscore (`'\037'`) character.

Messages in a Babyl mailbox have two sets of headers, original headers and so-called visible headers. Visible headers are typically a subset of the original headers that have been reformatted or abridged to be more attractive. Each message in a Babyl mailbox also has an accompanying list of *labels*, or short strings that record extra information about the message, and a list of all user-defined labels found in the mailbox is kept in the Babyl options section.

Babyl instances have all of the methods of *Mailbox* in addition to the following:

get_labels()
Return a list of the names of all user-defined labels used in the mailbox.

Note: The actual messages are inspected to determine which labels exist in the mailbox rather than consulting the list of labels in the Babyl options section, but the Babyl section is updated whenever the mailbox is modified.

Some *Mailbox* methods implemented by *Babyl* deserve special remarks:

get_file(*key*)
In Babyl mailboxes, the headers of a message are not stored contiguously with the body of the message. To generate a file-like representation, the headers and body are copied together into an *io.BytesIO* instance, which has an API identical to that of a file. As a result, the file-like object is truly independent of the underlying mailbox but does not save memory compared to a string representation.

lock()
unlock()
Three locking mechanisms are used—dot locking and, if available, the `flock()` and `lockf()` system calls.

See also:

Format of Version 5 Babyl Files A specification of the Babyl format.

Reading Mail with Rmail The Rmail manual, with some information on Babyl semantics.

MMDF

class mailbox.MMDF(*path*, *factory=None*, *create=True*)
A subclass of *Mailbox* for mailboxes in MMDF format. Parameter *factory* is a callable object that accepts a file-like message representation (which behaves as if opened in binary mode) and returns a custom representation. If *factory* is `None`, *MMDFMessage* is used as the default message representation. If *create* is `True`, the mailbox is created if it does not exist.

MMDF is a single-file mailbox format invented for the Multichannel Memorandum Distribution Facility, a mail transfer agent. Each message is in the same form as an mbox message but is bracketed before and after by lines containing four Control-A (`'\001'`) characters. As with the mbox format, the beginning of each message is indicated by a line whose first five characters are "From ", but additional occurrences of "From " are not transformed to ">From " when storing messages because the extra message separator lines prevent mistaking such occurrences for the starts of subsequent messages.

Some *Mailbox* methods implemented by *MMDF* deserve special remarks:

get_file(*key*)
Using the file after calling `flush()` or `close()` on the *MMDF* instance may yield unpredictable results or raise an exception.

lock()

`unlock()`
Three locking mechanisms are used—dot locking and, if available, the `flock()` and `lockf()` system calls.

See also:

mmdf man page from tin A specification of MMDF format from the documentation of tin, a newsreader.

MMDF A Wikipedia article describing the Multichannel Memorandum Distribution Facility.

20.4.2 `Message` objects

`class mailbox.Message(`*message=None*`)`
A subclass of the *email.message* module's *Message*. Subclasses of *mailbox.Message* add mailbox-format-specific state and behavior.

If *message* is omitted, the new instance is created in a default, empty state. If *message* is an *email.message.Message* instance, its contents are copied; furthermore, any format-specific information is converted insofar as possible if *message* is a *Message* instance. If *message* is a string, a byte string, or a file, it should contain an **RFC 2822**-compliant message, which is read and parsed. Files should be open in binary mode, but text mode files are accepted for backward compatibility.

The format-specific state and behaviors offered by subclasses vary, but in general it is only the properties that are not specific to a particular mailbox that are supported (although presumably the properties are specific to a particular mailbox format). For example, file offsets for single-file mailbox formats and file names for directory-based mailbox formats are not retained, because they are only applicable to the original mailbox. But state such as whether a message has been read by the user or marked as important is retained, because it applies to the message itself.

There is no requirement that *Message* instances be used to represent messages retrieved using *Mailbox* instances. In some situations, the time and memory required to generate *Message* representations might not be acceptable. For such situations, *Mailbox* instances also offer string and file-like representations, and a custom message factory may be specified when a *Mailbox* instance is initialized.

`MaildirMessage`

`class mailbox.MaildirMessage(`*message=None*`)`
A message with Maildir-specific behaviors. Parameter *message* has the same meaning as with the *Message* constructor.

Typically, a mail user agent application moves all of the messages in the `new` subdirectory to the `cur` subdirectory after the first time the user opens and closes the mailbox, recording that the messages are old whether or not they've actually been read. Each message in `cur` has an "info" section added to its file name to store information about its state. (Some mail readers may also add an "info" section to messages in `new`.) The "info" section may take one of two forms: it may contain "2," followed by a list of standardized flags (e.g., "2,FR") or it may contain "1," followed by so-called experimental information. Standard flags for Maildir messages are as follows:

Flag	Meaning	Explanation
D	Draft	Under composition
F	Flagged	Marked as important
P	Passed	Forwarded, resent, or bounced
R	Replied	Replied to
S	Seen	Read
T	Trashed	Marked for subsequent deletion

MaildirMessage instances offer the following methods:

get_subdir()
Return either "new" (if the message should be stored in the **new** subdirectory) or "cur" (if the message should be stored in the **cur** subdirectory).

Note: A message is typically moved from **new** to **cur** after its mailbox has been accessed, whether or not the message is has been read. A message **msg** has been read if **"S" in msg.get_flags()** is **True**.

---

set_subdir(*subdir*)
Set the subdirectory the message should be stored in. Parameter *subdir* must be either "new" or "cur".

get_flags()
Return a string specifying the flags that are currently set. If the message complies with the standard Maildir format, the result is the concatenation in alphabetical order of zero or one occurrence of each of **'D'**, **'F'**, **'P'**, **'R'**, **'S'**, and **'T'**. The empty string is returned if no flags are set or if "info" contains experimental semantics.

set_flags(*flags*)
Set the flags specified by *flags* and unset all others.

add_flag(*flag*)
Set the flag(s) specified by *flag* without changing other flags. To add more than one flag at a time, *flag* may be a string of more than one character. The current "info" is overwritten whether or not it contains experimental information rather than flags.

remove_flag(*flag*)
Unset the flag(s) specified by *flag* without changing other flags. To remove more than one flag at a time, *flag* maybe a string of more than one character. If "info" contains experimental information rather than flags, the current "info" is not modified.

get_date()
Return the delivery date of the message as a floating-point number representing seconds since the epoch.

set_date(*date*)
Set the delivery date of the message to *date*, a floating-point number representing seconds since the epoch.

get_info()
Return a string containing the "info" for a message. This is useful for accessing and modifying "info" that is experimental (i.e., not a list of flags).

set_info(*info*)
Set "info" to *info*, which should be a string.

When a *MaildirMessage* instance is created based upon an *mboxMessage* or *MMDFMessage* instance, the *Status* and *X-Status* headers are omitted and the following conversions take place:

Resulting state	*mboxMessage* or *MMDFMessage* state
"cur" subdirectory	O flag
F flag	F flag
R flag	A flag
S flag	R flag
T flag	D flag

When a *MaildirMessage* instance is created based upon an *MHMessage* instance, the following conversions take place:

Resulting state	*MHMessage* state
"cur" subdirectory	"unseen" sequence
"cur" subdirectory and S flag	no "unseen" sequence
F flag	"flagged" sequence
R flag	"replied" sequence

When a *MaildirMessage* instance is created based upon a *BabylMessage* instance, the following conversions take place:

Resulting state	*BabylMessage* state
"cur" subdirectory	"unseen" label
"cur" subdirectory and S flag	no "unseen" label
P flag	"forwarded" or "resent" label
R flag	"answered" label
T flag	"deleted" label

mboxMessage

class mailbox.**mboxMessage**(*message=None*)

A message with mbox-specific behaviors. Parameter *message* has the same meaning as with the *Message* constructor.

Messages in an mbox mailbox are stored together in a single file. The sender's envelope address and the time of delivery are typically stored in a line beginning with "From " that is used to indicate the start of a message, though there is considerable variation in the exact format of this data among mbox implementations. Flags that indicate the state of the message, such as whether it has been read or marked as important, are typically stored in ***Status*** and ***X-Status*** headers.

Conventional flags for mbox messages are as follows:

Flag	Meaning	Explanation
R	Read	Read
O	Old	Previously detected by MUA
D	Deleted	Marked for subsequent deletion
F	Flagged	Marked as important
A	Answered	Replied to

The "R" and "O" flags are stored in the ***Status*** header, and the "D", "F", and "A" flags are stored in the ***X-Status*** header. The flags and headers typically appear in the order mentioned.

mboxMessage instances offer the following methods:

get_from()

Return a string representing the "From " line that marks the start of the message in an mbox mailbox. The leading "From " and the trailing newline are excluded.

set_from(*from_*, *time_=None*)

Set the "From " line to *from_*, which should be specified without a leading "From " or trailing newline. For convenience, *time_* may be specified and will be formatted appropriately and appended to *from_*. If *time_* is specified, it should be a *time.struct_time* instance, a tuple suitable for passing to *time.strftime()*, or `True` (to use *time.gmtime()*).

`get_flags()`
Return a string specifying the flags that are currently set. If the message complies with the conventional format, the result is the concatenation in the following order of zero or one occurrence of each of `'R'`, `'O'`, `'D'`, `'F'`, and `'A'`.

`set_flags(`*flags*`)`
Set the flags specified by *flags* and unset all others. Parameter *flags* should be the concatenation in any order of zero or more occurrences of each of `'R'`, `'O'`, `'D'`, `'F'`, and `'A'`.

`add_flag(`*flag*`)`
Set the flag(s) specified by *flag* without changing other flags. To add more than one flag at a time, *flag* may be a string of more than one character.

`remove_flag(`*flag*`)`
Unset the flag(s) specified by *flag* without changing other flags. To remove more than one flag at a time, *flag* maybe a string of more than one character.

When an *mboxMessage* instance is created based upon a *MaildirMessage* instance, a "From " line is generated based upon the *MaildirMessage* instance's delivery date, and the following conversions take place:

Resulting state	*MaildirMessage* state
R flag	S flag
O flag	"cur" subdirectory
D flag	T flag
F flag	F flag
A flag	R flag

When an *mboxMessage* instance is created based upon an *MHMessage* instance, the following conversions take place:

Resulting state	*MHMessage* state
R flag and O flag	no "unseen" sequence
O flag	"unseen" sequence
F flag	"flagged" sequence
A flag	"replied" sequence

When an *mboxMessage* instance is created based upon a *BabylMessage* instance, the following conversions take place:

Resulting state	*BabylMessage* state
R flag and O flag	no "unseen" label
O flag	"unseen" label
D flag	"deleted" label
A flag	"answered" label

When a *Message* instance is created based upon an *MMDFMessage* instance, the "From " line is copied and all flags directly correspond:

Resulting state	*MMDFMessage* state
R flag	R flag
O flag	O flag
D flag	D flag
F flag	F flag
A flag	A flag

MHMessage

class mailbox.**MHMessage**(*message=None*)

A message with MH-specific behaviors. Parameter *message* has the same meaning as with the *Message* constructor.

MH messages do not support marks or flags in the traditional sense, but they do support sequences, which are logical groupings of arbitrary messages. Some mail reading programs (although not the standard **mh** and **nmh**) use sequences in much the same way flags are used with other formats, as follows:

Sequence	Explanation
unseen	Not read, but previously detected by MUA
replied	Replied to
flagged	Marked as important

MHMessage instances offer the following methods:

get_sequences()

Return a list of the names of sequences that include this message.

set_sequences(*sequences*)

Set the list of sequences that include this message.

add_sequence(*sequence*)

Add *sequence* to the list of sequences that include this message.

remove_sequence(*sequence*)

Remove *sequence* from the list of sequences that include this message.

When an *MHMessage* instance is created based upon a *MaildirMessage* instance, the following conversions take place:

Resulting state	*MaildirMessage* state
“unseen” sequence	no S flag
“replied” sequence	R flag
“flagged” sequence	F flag

When an *MHMessage* instance is created based upon an *mboxMessage* or *MMDFMessage* instance, the ***Status*** and ***X-Status*** headers are omitted and the following conversions take place:

Resulting state	*mboxMessage* or *MMDFMessage* state
“unseen” sequence	no R flag
“replied” sequence	A flag
“flagged” sequence	F flag

When an *MHMessage* instance is created based upon a *BabylMessage* instance, the following conversions take place:

Resulting state	*BabylMessage* state
“unseen” sequence	“unseen” label
“replied” sequence	“answered” label

BabylMessage

class mailbox.BabylMessage(*message=None*)

A message with Babyl-specific behaviors. Parameter *message* has the same meaning as with the *Message* constructor.

Certain message labels, called *attributes*, are defined by convention to have special meanings. The attributes are as follows:

Label	Explanation
unseen	Not read, but previously detected by MUA
deleted	Marked for subsequent deletion
filed	Copied to another file or mailbox
answered	Replied to
forwarded	Forwarded
edited	Modified by the user
resent	Resent

By default, Rmail displays only visible headers. The *BabylMessage* class, though, uses the original headers because they are more complete. Visible headers may be accessed explicitly if desired.

BabylMessage instances offer the following methods:

get_labels()

Return a list of labels on the message.

set_labels(*labels*)

Set the list of labels on the message to *labels*.

add_label(*label*)

Add *label* to the list of labels on the message.

remove_label(*label*)

Remove *label* from the list of labels on the message.

get_visible()

Return an *Message* instance whose headers are the message's visible headers and whose body is empty.

set_visible(*visible*)

Set the message's visible headers to be the same as the headers in *message*. Parameter *visible* should be a *Message* instance, an *email.message.Message* instance, a string, or a file-like object (which should be open in text mode).

update_visible()

When a *BabylMessage* instance's original headers are modified, the visible headers are not automatically modified to correspond. This method updates the visible headers as follows: each visible header with a corresponding original header is set to the value of the original header, each visible header without a corresponding original header is removed, and any of *Date*, *From*, *Reply-To*, *To*, *CC*, and *Subject* that are present in the original headers but not the visible headers are added to the visible headers.

When a *BabylMessage* instance is created based upon a *MaildirMessage* instance, the following conversions take place:

Resulting state	*MaildirMessage* state
“unseen” label	no S flag
“deleted” label	T flag
“answered” label	R flag
“forwarded” label	P flag

When a *BabylMessage* instance is created based upon an *mboxMessage* or *MMDFMessage* instance, the ***Status*** and ***X-Status*** headers are omitted and the following conversions take place:

Resulting state	*mboxMessage* or *MMDFMessage* state
“unseen” label	no R flag
“deleted” label	D flag
“answered” label	A flag

When a *BabylMessage* instance is created based upon an *MHMessage* instance, the following conversions take place:

Resulting state	*MHMessage* state
“unseen” label	“unseen” sequence
“answered” label	“replied” sequence

MMDFMessage

class mailbox.**MMDFMessage**(*message=None*)

A message with MMDF-specific behaviors. Parameter *message* has the same meaning as with the *Message* constructor.

As with message in an mbox mailbox, MMDF messages are stored with the sender’s address and the delivery date in an initial line beginning with “From “. Likewise, flags that indicate the state of the message are typically stored in ***Status*** and ***X-Status*** headers.

Conventional flags for MMDF messages are identical to those of mbox message and are as follows:

Flag	Meaning	Explanation
R	Read	Read
O	Old	Previously detected by MUA
D	Deleted	Marked for subsequent deletion
F	Flagged	Marked as important
A	Answered	Replied to

The “R” and “O” flags are stored in the ***Status*** header, and the “D”, “F”, and “A” flags are stored in the ***X-Status*** header. The flags and headers typically appear in the order mentioned.

MMDFMessage instances offer the following methods, which are identical to those offered by *mboxMessage*:

get_from()

Return a string representing the “From ” line that marks the start of the message in an mbox mailbox. The leading “From ” and the trailing newline are excluded.

set_from(*from_*, *time_=None*)

Set the “From ” line to *from_*, which should be specified without a leading “From ” or trailing newline. For convenience, *time_* may be specified and will be formatted appropriately and

appended to *from_*. If *time_* is specified, it should be a *time.struct_time* instance, a tuple suitable for passing to *time.strftime()*, or `True` (to use *time.gmtime()*).

get_flags()
Return a string specifying the flags that are currently set. If the message complies with the conventional format, the result is the concatenation in the following order of zero or one occurrence of each of `'R'`, `'O'`, `'D'`, `'F'`, and `'A'`.

set_flags(*flags***)**
Set the flags specified by *flags* and unset all others. Parameter *flags* should be the concatenation in any order of zero or more occurrences of each of `'R'`, `'O'`, `'D'`, `'F'`, and `'A'`.

add_flag(*flag***)**
Set the flag(s) specified by *flag* without changing other flags. To add more than one flag at a time, *flag* may be a string of more than one character.

remove_flag(*flag***)**
Unset the flag(s) specified by *flag* without changing other flags. To remove more than one flag at a time, *flag* maybe a string of more than one character.

When an *MMDFMessage* instance is created based upon a *MaildirMessage* instance, a "From " line is generated based upon the *MaildirMessage* instance's delivery date, and the following conversions take place:

Resulting state	*MaildirMessage* state
R flag	S flag
O flag	"cur" subdirectory
D flag	T flag
F flag	F flag
A flag	R flag

When an *MMDFMessage* instance is created based upon an *MHMessage* instance, the following conversions take place:

Resulting state	*MHMessage* state
R flag and O flag	no "unseen" sequence
O flag	"unseen" sequence
F flag	"flagged" sequence
A flag	"replied" sequence

When an *MMDFMessage* instance is created based upon a *BabylMessage* instance, the following conversions take place:

Resulting state	*BabylMessage* state
R flag and O flag	no "unseen" label
O flag	"unseen" label
D flag	"deleted" label
A flag	"answered" label

When an *MMDFMessage* instance is created based upon an *mboxMessage* instance, the "From " line is copied and all flags directly correspond:

Resulting state	*mboxMessage* state
R flag	R flag
O flag	O flag
D flag	D flag
F flag	F flag
A flag	A flag

20.4.3 Exceptions

The following exception classes are defined in the *mailbox* module:

exception mailbox.**Error**
The based class for all other module-specific exceptions.

exception mailbox.**NoSuchMailboxError**
Raised when a mailbox is expected but is not found, such as when instantiating a *Mailbox* subclass with a path that does not exist (and with the *create* parameter set to `False`), or when opening a folder that does not exist.

exception mailbox.**NotEmptyError**
Raised when a mailbox is not empty but is expected to be, such as when deleting a folder that contains messages.

exception mailbox.**ExternalClashError**
Raised when some mailbox-related condition beyond the control of the program causes it to be unable to proceed, such as when failing to acquire a lock that another program already holds a lock, or when a uniquely-generated file name already exists.

exception mailbox.**FormatError**
Raised when the data in a file cannot be parsed, such as when an *MH* instance attempts to read a corrupted `.mh_sequences` file.

20.4.4 Examples

A simple example of printing the subjects of all messages in a mailbox that seem interesting:

```
import mailbox
for message in mailbox.mbox('~/mbox'):
    subject = message['subject']       # Could possibly be None.
    if subject and 'python' in subject.lower():
        print(subject)
```

To copy all mail from a Babyl mailbox to an MH mailbox, converting all of the format-specific information that can be converted:

```
import mailbox
destination = mailbox.MH('~/Mail')
destination.lock()
for message in mailbox.Babyl('~/RMAIL'):
    destination.add(mailbox.MHMessage(message))
destination.flush()
destination.unlock()
```

This example sorts mail from several mailing lists into different mailboxes, being careful to avoid mail corruption due to concurrent modification by other programs, mail loss due to interruption of the program, or premature termination due to malformed messages in the mailbox:

```
import mailbox
import email.errors

list_names = ('python-list', 'python-dev', 'python-bugs')

boxes = {name: mailbox.mbox('~/email/%s' % name) for name in list_names}
inbox = mailbox.Maildir('~/Maildir', factory=None)

for key in inbox.iterkeys():
    try:
        message = inbox[key]
    except email.errors.MessageParseError:
        continue                # The message is malformed. Just leave it.

    for name in list_names:
        list_id = message['list-id']
        if list_id and name in list_id:
            # Get mailbox to use
            box = boxes[name]

            # Write copy to disk before removing original.
            # If there's a crash, you might duplicate a message, but
            # that's better than losing a message completely.
            box.lock()
            box.add(message)
            box.flush()
            box.unlock()

            # Remove original message
            inbox.lock()
            inbox.discard(key)
            inbox.flush()
            inbox.unlock()
            break               # Found destination, so stop looking.

for box in boxes.itervalues():
    box.close()
```

20.5 mimetypes — Map filenames to MIME types

Source code: Lib/mimetypes.py

The *mimetypes* module converts between a filename or URL and the MIME type associated with the filename extension. Conversions are provided from filename to MIME type and from MIME type to filename extension; encodings are not supported for the latter conversion.

The module provides one class and a number of convenience functions. The functions are the normal interface to this module, but some applications may be interested in the class as well.

The functions described below provide the primary interface for this module. If the module has not been initialized, they will call *init()* if they rely on the information *init()* sets up.

mimetypes.**guess_type**(*url*, *strict=True*)

Guess the type of a file based on its filename or URL, given by *url*. The return value is a tuple `(type,`

encoding) where *type* is None if the type can't be guessed (missing or unknown suffix) or a string of the form 'type/subtype', usable for a MIME *content-type* header.

encoding is None for no encoding or the name of the program used to encode (e.g. **compress** or **gzip**). The encoding is suitable for use as a *Content-Encoding* header, **not** as a *Content-Transfer-Encoding* header. The mappings are table driven. Encoding suffixes are case sensitive; type suffixes are first tried case sensitively, then case insensitively.

The optional *strict* argument is a flag specifying whether the list of known MIME types is limited to only the official types registered with IANA. When *strict* is True (the default), only the IANA types are supported; when *strict* is False, some additional non-standard but commonly used MIME types are also recognized.

mimetypes.**guess_all_extensions**(*type*, *strict=True*)
Guess the extensions for a file based on its MIME type, given by *type*. The return value is a list of strings giving all possible filename extensions, including the leading dot ('.'). The extensions are not guaranteed to have been associated with any particular data stream, but would be mapped to the MIME type *type* by *guess_type()*.

The optional *strict* argument has the same meaning as with the *guess_type()* function.

mimetypes.**guess_extension**(*type*, *strict=True*)
Guess the extension for a file based on its MIME type, given by *type*. The return value is a string giving a filename extension, including the leading dot ('.'). The extension is not guaranteed to have been associated with any particular data stream, but would be mapped to the MIME type *type* by *guess_type()*. If no extension can be guessed for *type*, None is returned.

The optional *strict* argument has the same meaning as with the *guess_type()* function.

Some additional functions and data items are available for controlling the behavior of the module.

mimetypes.**init**(*files=None*)
Initialize the internal data structures. If given, *files* must be a sequence of file names which should be used to augment the default type map. If omitted, the file names to use are taken from *knownfiles*; on Windows, the current registry settings are loaded. Each file named in *files* or *knownfiles* takes precedence over those named before it. Calling *init()* repeatedly is allowed.

Specifying an empty list for *files* will prevent the system defaults from being applied: only the well-known values will be present from a built-in list.

Changed in version 3.2: Previously, Windows registry settings were ignored.

mimetypes.**read_mime_types**(*filename*)
Load the type map given in the file *filename*, if it exists. The type map is returned as a dictionary mapping filename extensions, including the leading dot ('.'), to strings of the form 'type/subtype'. If the file *filename* does not exist or cannot be read, None is returned.

mimetypes.**add_type**(*type*, *ext*, *strict=True*)
Add a mapping from the MIME type *type* to the extension *ext*. When the extension is already known, the new type will replace the old one. When the type is already known the extension will be added to the list of known extensions.

When *strict* is True (the default), the mapping will be added to the official MIME types, otherwise to the non-standard ones.

mimetypes.**inited**
Flag indicating whether or not the global data structures have been initialized. This is set to True by *init()*.

mimetypes.**knownfiles**
List of type map file names commonly installed. These files are typically named mime.types and are installed in different locations by different packages.

mimetypes.suffix_map
Dictionary mapping suffixes to suffixes. This is used to allow recognition of encoded files for which the encoding and the type are indicated by the same extension. For example, the `.tgz` extension is mapped to `.tar.gz` to allow the encoding and type to be recognized separately.

mimetypes.encodings_map
Dictionary mapping filename extensions to encoding types.

mimetypes.types_map
Dictionary mapping filename extensions to MIME types.

mimetypes.common_types
Dictionary mapping filename extensions to non-standard, but commonly found MIME types.

An example usage of the module:

```
>>> import mimetypes
>>> mimetypes.init()
>>> mimetypes.knownfiles
['/etc/mime.types', '/etc/httpd/mime.types', ... ]
>>> mimetypes.suffix_map['.tgz']
'.tar.gz'
>>> mimetypes.encodings_map['.gz']
'gzip'
>>> mimetypes.types_map['.tgz']
'application/x-tar-gz'
```

20.5.1 MimeTypes Objects

The *MimeTypes* class may be useful for applications which may want more than one MIME-type database; it provides an interface similar to the one of the *mimetypes* module.

class mimetypes.MimeTypes(*filenames=()*, *strict=True*)
This class represents a MIME-types database. By default, it provides access to the same database as the rest of this module. The initial database is a copy of that provided by the module, and may be extended by loading additional `mime.types`-style files into the database using the *read()* or *readfp()* methods. The mapping dictionaries may also be cleared before loading additional data if the default data is not desired.

The optional *filenames* parameter can be used to cause additional files to be loaded "on top" of the default database.

suffix_map
Dictionary mapping suffixes to suffixes. This is used to allow recognition of encoded files for which the encoding and the type are indicated by the same extension. For example, the `.tgz` extension is mapped to `.tar.gz` to allow the encoding and type to be recognized separately. This is initially a copy of the global *suffix_map* defined in the module.

encodings_map
Dictionary mapping filename extensions to encoding types. This is initially a copy of the global *encodings_map* defined in the module.

types_map
Tuple containing two dictionaries, mapping filename extensions to MIME types: the first dictionary is for the non-standards types and the second one is for the standard types. They are initialized by *common_types* and *types_map*.

types_map_inv
Tuple containing two dictionaries, mapping MIME types to a list of filename extensions: the first

dictionary is for the non-standards types and the second one is for the standard types. They are initialized by *common_types* and *types_map*.

guess_extension(*type*, *strict=True*)
Similar to the *guess_extension()* function, using the tables stored as part of the object.

guess_type(*url*, *strict=True*)
Similar to the *guess_type()* function, using the tables stored as part of the object.

guess_all_extensions(*type*, *strict=True*)
Similar to the *guess_all_extensions()* function, using the tables stored as part of the object.

read(*filename*, *strict=True*)
Load MIME information from a file named *filename*. This uses *readfp()* to parse the file.

If *strict* is `True`, information will be added to list of standard types, else to the list of non-standard types.

readfp(*fp*, *strict=True*)
Load MIME type information from an open file *fp*. The file must have the format of the standard `mime.types` files.

If *strict* is `True`, information will be added to the list of standard types, else to the list of non-standard types.

read_windows_registry(*strict=True*)
Load MIME type information from the Windows registry. Availability: Windows.

If *strict* is `True`, information will be added to the list of standard types, else to the list of non-standard types.

New in version 3.2.

20.6 base64 — Base16, Base32, Base64, Base85 Data Encodings

Source code: Lib/base64.py

This module provides functions for encoding binary data to printable ASCII characters and decoding such encodings back to binary data. It provides encoding and decoding functions for the encodings specified in **RFC 3548**, which defines the Base16, Base32, and Base64 algorithms, and for the de-facto standard Ascii85 and Base85 encodings.

The **RFC 3548** encodings are suitable for encoding binary data so that it can safely sent by email, used as parts of URLs, or included as part of an HTTP POST request. The encoding algorithm is not the same as the **uuencode** program.

There are two interfaces provided by this module. The modern interface supports encoding *bytes-like objects* to ASCII *bytes*, and decoding *bytes-like objects* or strings containing ASCII to *bytes*. Both base-64 alphabets defined in **RFC 3548** (normal, and URL- and filesystem-safe) are supported.

The legacy interface does not support decoding from strings, but it does provide functions for encoding and decoding to and from *file objects*. It only supports the Base64 standard alphabet, and it adds newlines every 76 characters as per **RFC 2045**. Note that if you are looking for **RFC 2045** support you probably want to be looking at the *email* package instead.

Changed in version 3.3: ASCII-only Unicode strings are now accepted by the decoding functions of the modern interface.

Changed in version 3.4: Any *bytes-like objects* are now accepted by all encoding and decoding functions in this module. Ascii85/Base85 support added.

The modern interface provides:

base64.b64encode(*s*, *altchars=None*)
Encode the *bytes-like object* *s* using Base64 and return the encoded *bytes*.

Optional *altchars* must be a *bytes-like object* of at least length 2 (additional characters are ignored) which specifies an alternative alphabet for the `+` and `/` characters. This allows an application to e.g. generate URL or filesystem safe Base64 strings. The default is `None`, for which the standard Base64 alphabet is used.

base64.b64decode(*s*, *altchars=None*, *validate=False*)
Decode the Base64 encoded *bytes-like object* or ASCII string *s* and return the decoded *bytes*.

Optional *altchars* must be a *bytes-like object* or ASCII string of at least length 2 (additional characters are ignored) which specifies the alternative alphabet used instead of the `+` and `/` characters.

A *binascii.Error* exception is raised if *s* is incorrectly padded.

If *validate* is `False` (the default), characters that are neither in the normal base-64 alphabet nor the alternative alphabet are discarded prior to the padding check. If *validate* is `True`, these non-alphabet characters in the input result in a *binascii.Error*.

base64.standard_b64encode(*s*)
Encode *bytes-like object* *s* using the standard Base64 alphabet and return the encoded *bytes*.

base64.standard_b64decode(*s*)
Decode *bytes-like object* or ASCII string *s* using the standard Base64 alphabet and return the decoded *bytes*.

base64.urlsafe_b64encode(*s*)
Encode *bytes-like object* *s* using the URL- and filesystem-safe alphabet, which substitutes `-` instead of `+` and `_` instead of `/` in the standard Base64 alphabet, and return the encoded *bytes*. The result can still contain `=`.

base64.urlsafe_b64decode(*s*)
Decode *bytes-like object* or ASCII string *s* using the URL- and filesystem-safe alphabet, which substitutes `-` instead of `+` and `_` instead of `/` in the standard Base64 alphabet, and return the decoded *bytes*.

base64.b32encode(*s*)
Encode the *bytes-like object* *s* using Base32 and return the encoded *bytes*.

base64.b32decode(*s*, *casefold=False*, *map01=None*)
Decode the Base32 encoded *bytes-like object* or ASCII string *s* and return the decoded *bytes*.

Optional *casefold* is a flag specifying whether a lowercase alphabet is acceptable as input. For security purposes, the default is `False`.

RFC 3548 allows for optional mapping of the digit 0 (zero) to the letter O (oh), and for optional mapping of the digit 1 (one) to either the letter I (eye) or letter L (el). The optional argument *map01* when not `None`, specifies which letter the digit 1 should be mapped to (when *map01* is not `None`, the digit 0 is always mapped to the letter O). For security purposes the default is `None`, so that 0 and 1 are not allowed in the input.

A *binascii.Error* is raised if *s* is incorrectly padded or if there are non-alphabet characters present in the input.

base64.b16encode(*s*)
Encode the *bytes-like object* *s* using Base16 and return the encoded *bytes*.

base64.b16decode(*s*, *casefold=False*)
Decode the Base16 encoded *bytes-like object* or ASCII string *s* and return the decoded *bytes*.

Optional *casefold* is a flag specifying whether a lowercase alphabet is acceptable as input. For security purposes, the default is `False`.

A *binascii.Error* is raised if *s* is incorrectly padded or if there are non-alphabet characters present in the input.

`base64.a85encode`(*b*, ***, *foldspaces=False*, *wrapcol=0*, *pad=False*, *adobe=False*)
Encode the *bytes-like object* *b* using Ascii85 and return the encoded *bytes*.

foldspaces is an optional flag that uses the special short sequence 'y' instead of 4 consecutive spaces (ASCII 0x20) as supported by 'btoa'. This feature is not supported by the "standard" Ascii85 encoding.

wrapcol controls whether the output should have newline (`b'\n'`) characters added to it. If this is non-zero, each output line will be at most this many characters long.

pad controls whether the input is padded to a multiple of 4 before encoding. Note that the `btoa` implementation always pads.

adobe controls whether the encoded byte sequence is framed with `<~` and `~>`, which is used by the Adobe implementation.

New in version 3.4.

`base64.a85decode`(*b*, ***, *foldspaces=False*, *adobe=False*, *ignorechars=b' \t\n\r\v'*)
Decode the Ascii85 encoded *bytes-like object* or ASCII string *b* and return the decoded *bytes*.

foldspaces is a flag that specifies whether the 'y' short sequence should be accepted as shorthand for 4 consecutive spaces (ASCII 0x20). This feature is not supported by the "standard" Ascii85 encoding.

adobe controls whether the input sequence is in Adobe Ascii85 format (i.e. is framed with <~ and ~>).

ignorechars should be a *bytes-like object* or ASCII string containing characters to ignore from the input. This should only contain whitespace characters, and by default contains all whitespace characters in ASCII.

New in version 3.4.

`base64.b85encode`(*b*, *pad=False*)
Encode the *bytes-like object* *b* using base85 (as used in e.g. git-style binary diffs) and return the encoded *bytes*.

If *pad* is true, the input is padded with `b'\0'` so its length is a multiple of 4 bytes before encoding.

New in version 3.4.

`base64.b85decode`(*b*)
Decode the base85-encoded *bytes-like object* or ASCII string *b* and return the decoded *bytes*. Padding is implicitly removed, if necessary.

New in version 3.4.

The legacy interface:

`base64.decode`(*input*, *output*)
Decode the contents of the binary *input* file and write the resulting binary data to the *output* file. *input* and *output* must be *file objects*. *input* will be read until `input.readline()` returns an empty bytes object.

`base64.decodebytes`(*s*)
Decode the *bytes-like object* *s*, which must contain one or more lines of base64 encoded data, and return the decoded *bytes*.

New in version 3.1.

`base64.decodestring`(*s*)
Deprecated alias of *decodebytes()*.

Deprecated since version 3.1.

base64.encode(*input*, *output*)
Encode the contents of the binary *input* file and write the resulting base64 encoded data to the *output* file. *input* and *output* must be *file objects*. *input* will be read until `input.read()` returns an empty bytes object. *encode()* inserts a newline character (`b'\n'`) after every 76 bytes of the output, as well as ensuring that the output always ends with a newline, as per **RFC 2045** (MIME).

base64.encodebytes(*s*)
Encode the *bytes-like object* *s*, which can contain arbitrary binary data, and return *bytes* containing the base64-encoded data, with newlines (`b'\n'`) inserted after every 76 bytes of output, and ensuring that there is a trailing newline, as per **RFC 2045** (MIME).

New in version 3.1.

base64.encodestring(*s*)
Deprecated alias of *encodebytes()*.

Deprecated since version 3.1.

An example usage of the module:

```
>>> import base64
>>> encoded = base64.b64encode(b'data to be encoded')
>>> encoded
b'ZGF0YSBOYyBiZSBlbmNvZGVk'
>>> data = base64.b64decode(encoded)
>>> data
b'data to be encoded'
```

Module *binascii* Support module containing ASCII-to-binary and binary-to-ASCII conversions.

RFC 1521 - MIME (Multipurpose Internet Mail Extensions) Part One: Mechanisms for Specifying and Des
Section 5.2, "Base64 Content-Transfer-Encoding," provides the definition of the base64 encoding.

20.7 binhex — Encode and decode binhex4 files

Source code: Lib/binhex.py

This module encodes and decodes files in binhex4 format, a format allowing representation of Macintosh files in ASCII. Only the data fork is handled.

The *binhex* module defines the following functions:

binhex.binhex(*input*, *output*)
Convert a binary file with filename *input* to binhex file *output*. The *output* parameter can either be a filename or a file-like object (any object supporting a `write()` and `close()` method).

binhex.hexbin(*input*, *output*)
Decode a binhex file *input*. *input* may be a filename or a file-like object supporting `read()` and `close()` methods. The resulting file is written to a file named *output*, unless the argument is `None` in which case the output filename is read from the binhex file.

The following exception is also defined:

exception binhex.Error
Exception raised when something can't be encoded using the binhex format (for example, a filename is too long to fit in the filename field), or when input is not properly encoded binhex data.

See also:

Module *binascii* Support module containing ASCII-to-binary and binary-to-ASCII conversions.

20.7.1 Notes

There is an alternative, more powerful interface to the coder and decoder, see the source for details.

If you code or decode textfiles on non-Macintosh platforms they will still use the old Macintosh newline convention (carriage-return as end of line).

20.8 binascii — Convert between binary and ASCII

The *binascii* module contains a number of methods to convert between binary and various ASCII-encoded binary representations. Normally, you will not use these functions directly but use wrapper modules like *uu*, *base64*, or *binhex* instead. The *binascii* module contains low-level functions written in C for greater speed that are used by the higher-level modules.

Note: `a2b_*` functions accept Unicode strings containing only ASCII characters. Other functions only accept *bytes-like objects* (such as *bytes*, *bytearray* and other objects that support the buffer protocol).

Changed in version 3.3: ASCII-only unicode strings are now accepted by the `a2b_*` functions.

The *binascii* module defines the following functions:

`binascii.a2b_uu(`*string*`)`
: Convert a single line of uuencoded data back to binary and return the binary data. Lines normally contain 45 (binary) bytes, except for the last line. Line data may be followed by whitespace.

`binascii.b2a_uu(`*data*, ***, *backtick=False*`)`
: Convert binary data to a line of ASCII characters, the return value is the converted line, including a newline char. The length of *data* should be at most 45. If *backtick* is true, zeros are represented by `'`'` instead of spaces.

  Changed in version 3.7: Added the *backtick* parameter.

`binascii.a2b_base64(`*string*`)`
: Convert a block of base64 data back to binary and return the binary data. More than one line may be passed at a time.

`binascii.b2a_base64(`*data*, ***, *newline=True*`)`
: Convert binary data to a line of ASCII characters in base64 coding. The return value is the converted line, including a newline char if *newline* is true. The output of this function conforms to **RFC 3548**.

  Changed in version 3.6: Added the *newline* parameter.

`binascii.a2b_qp(`*data*, *header=False*`)`
: Convert a block of quoted-printable data back to binary and return the binary data. More than one line may be passed at a time. If the optional argument *header* is present and true, underscores will be decoded as spaces.

`binascii.b2a_qp(`*data*, *quotetabs=False*, *istext=True*, *header=False*`)`
: Convert binary data to a line(s) of ASCII characters in quoted-printable encoding. The return value is the converted line(s). If the optional argument *quotetabs* is present and true, all tabs and spaces will be encoded. If the optional argument *istext* is present and true, newlines are not encoded but

trailing whitespace will be encoded. If the optional argument *header* is present and true, spaces will be encoded as underscores per **RFC 1522**. If the optional argument *header* is present and false, newline characters will be encoded as well; otherwise linefeed conversion might corrupt the binary data stream.

binascii.a2b_hqx(*string*)
Convert binhex4 formatted ASCII data to binary, without doing RLE-decompression. The string should contain a complete number of binary bytes, or (in case of the last portion of the binhex4 data) have the remaining bits zero.

binascii.rledecode_hqx(*data*)
Perform RLE-decompression on the data, as per the binhex4 standard. The algorithm uses `0x90` after a byte as a repeat indicator, followed by a count. A count of `0` specifies a byte value of `0x90`. The routine returns the decompressed data, unless data input data ends in an orphaned repeat indicator, in which case the *Incomplete* exception is raised.

Changed in version 3.2: Accept only bytestring or bytearray objects as input.

binascii.rlecode_hqx(*data*)
Perform binhex4 style RLE-compression on *data* and return the result.

binascii.b2a_hqx(*data*)
Perform hexbin4 binary-to-ASCII translation and return the resulting string. The argument should already be RLE-coded, and have a length divisible by 3 (except possibly the last fragment).

binascii.crc_hqx(*data*, *value*)
Compute a 16-bit CRC value of *data*, starting with *value* as the initial CRC, and return the result. This uses the CRC-CCITT polynomial $x^{16} + x^{12} + x^5 + 1$, often represented as 0x1021. This CRC is used in the binhex4 format.

binascii.crc32(*data*[, *value*])
Compute CRC-32, the 32-bit checksum of *data*, starting with an initial CRC of *value*. The default initial CRC is zero. The algorithm is consistent with the ZIP file checksum. Since the algorithm is designed for use as a checksum algorithm, it is not suitable for use as a general hash algorithm. Use as follows:

```
print(binascii.crc32(b"hello world"))
# Or, in two pieces:
crc = binascii.crc32(b"hello")
crc = binascii.crc32(b" world", crc)
print('crc32 = {:#010x}'.format(crc))
```

Changed in version 3.0: The result is always unsigned. To generate the same numeric value across all Python versions and platforms, use `crc32(data) & 0xffffffff`.

binascii.b2a_hex(*data*)
binascii.hexlify(*data*)
Return the hexadecimal representation of the binary *data*. Every byte of *data* is converted into the corresponding 2-digit hex representation. The returned bytes object is therefore twice as long as the length of *data*.

binascii.a2b_hex(*hexstr*)
binascii.unhexlify(*hexstr*)
Return the binary data represented by the hexadecimal string *hexstr*. This function is the inverse of *b2a_hex()*. *hexstr* must contain an even number of hexadecimal digits (which can be upper or lower case), otherwise an *Error* exception is raised.

exception binascii.Error
Exception raised on errors. These are usually programming errors.

exception binascii.Incomplete
Exception raised on incomplete data. These are usually not programming errors, but may be handled

by reading a little more data and trying again.

Module *base64* Support for RFC compliant base64-style encoding in base 16, 32, 64, and 85.

Module *binhex* Support for the binhex format used on the Macintosh.

Module *uu* Support for UU encoding used on Unix.

Module *quopri* Support for quoted-printable encoding used in MIME email messages.

20.9 quopri — Encode and decode MIME quoted-printable data

Source code: Lib/quopri.py

This module performs quoted-printable transport encoding and decoding, as defined in **RFC 1521**: "MIME (Multipurpose Internet Mail Extensions) Part One: Mechanisms for Specifying and Describing the Format of Internet Message Bodies". The quoted-printable encoding is designed for data where there are relatively few nonprintable characters; the base64 encoding scheme available via the *base64* module is more compact if there are many such characters, as when sending a graphics file.

`quopri.decode`(*input*, *output*, *header=False*)
Decode the contents of the *input* file and write the resulting decoded binary data to the *output* file. *input* and *output* must be *binary file objects*. If the optional argument *header* is present and true, underscore will be decoded as space. This is used to decode "Q"-encoded headers as described in **RFC 1522**: "MIME (Multipurpose Internet Mail Extensions) Part Two: Message Header Extensions for Non-ASCII Text".

`quopri.encode`(*input*, *output*, *quotetabs*, *header=False*)
Encode the contents of the *input* file and write the resulting quoted-printable data to the *output* file. *input* and *output* must be *binary file objects*. *quotetabs*, a non-optional flag which controls whether to encode embedded spaces and tabs; when true it encodes such embedded whitespace, and when false it leaves them unencoded. Note that spaces and tabs appearing at the end of lines are always encoded, as per **RFC 1521**. *header* is a flag which controls if spaces are encoded as underscores as per **RFC 1522**.

`quopri.decodestring`(*s*, *header=False*)
Like *decode()*, except that it accepts a source *bytes* and returns the corresponding decoded *bytes*.

`quopri.encodestring`(*s*, *quotetabs=False*, *header=False*)
Like *encode()*, except that it accepts a source *bytes* and returns the corresponding encoded *bytes*. By default, it sends a `False` value to *quotetabs* parameter of the *encode()* function.

Module *base64* Encode and decode MIME base64 data

20.10 uu — Encode and decode uuencode files

Source code: Lib/uu.py

This module encodes and decodes files in uuencode format, allowing arbitrary binary data to be transferred over ASCII-only connections. Wherever a file argument is expected, the methods accept a file-like object. For backwards compatibility, a string containing a pathname is also accepted, and the corresponding file will

be opened for reading and writing; the pathname `'-'` is understood to mean the standard input or output. However, this interface is deprecated; it's better for the caller to open the file itself, and be sure that, when required, the mode is `'rb'` or `'wb'` on Windows.

This code was contributed by Lance Ellinghouse, and modified by Jack Jansen.

The *uu* module defines the following functions:

uu.encode(*in_file*, *out_file*, *name=None*, *mode=None*, ***, *backtick=False*)
Uuencode file *in_file* into file *out_file*. The uuencoded file will have the header specifying *name* and *mode* as the defaults for the results of decoding the file. The default defaults are taken from *in_file*, or `'-'` and `0o666` respectively. If *backtick* is true, zeros are represented by `'`'` instead of spaces.

Changed in version 3.7: Added the *backtick* parameter.

uu.decode(*in_file*, *out_file=None*, *mode=None*, *quiet=False*)
This call decodes uuencoded file *in_file* placing the result on file *out_file*. If *out_file* is a pathname, *mode* is used to set the permission bits if the file must be created. Defaults for *out_file* and *mode* are taken from the uuencode header. However, if the file specified in the header already exists, a *uu.Error* is raised.

decode() may print a warning to standard error if the input was produced by an incorrect uuencoder and Python could recover from that error. Setting *quiet* to a true value silences this warning.

exception uu.Error
Subclass of *Exception*, this can be raised by *uu.decode()* under various situations, such as described above, but also including a badly formatted header, or truncated input file.

CHAPTER

TWENTYONE

STRUCTURED MARKUP PROCESSING TOOLS

Python supports a variety of modules to work with various forms of structured data markup. This includes modules to work with the Standard Generalized Markup Language (SGML) and the Hypertext Markup Language (HTML), and several interfaces for working with the Extensible Markup Language (XML).

21.1 `html` — HyperText Markup Language support

Source code: Lib/html/__init__.py

This module defines utilities to manipulate HTML.

`html.escape`(*s*, *quote=True*)
Convert the characters `&`, `<` and `>` in string *s* to HTML-safe sequences. Use this if you need to display text that might contain such characters in HTML. If the optional flag *quote* is true, the characters (`"`) and (`'`) are also translated; this helps for inclusion in an HTML attribute value delimited by quotes, as in `<a href="...">`.

New in version 3.2.

`html.unescape`(*s*)
Convert all named and numeric character references (e.g. `>`, `&#62;`, `&x3e;`) in the string *s* to the corresponding unicode characters. This function uses the rules defined by the HTML 5 standard for both valid and invalid character references, and the *list of HTML 5 named character references*.

New in version 3.4.

Submodules in the `html` package are:

- *`html.parser`* – HTML/XHTML parser with lenient parsing mode
- *`html.entities`* – HTML entity definitions

21.2 `html.parser` — Simple HTML and XHTML parser

Source code: Lib/html/parser.py

This module defines a class *`HTMLParser`* which serves as the basis for parsing text files formatted in HTML (HyperText Mark-up Language) and XHTML.

class html.parser.HTMLParser(*, *convert_charrefs=True*)

Create a parser instance able to parse invalid markup.

If *convert_charrefs* is `True` (the default), all character references (except the ones in `script`/`style` elements) are automatically converted to the corresponding Unicode characters.

An *HTMLParser* instance is fed HTML data and calls handler methods when start tags, end tags, text, comments, and other markup elements are encountered. The user should subclass *HTMLParser* and override its methods to implement the desired behavior.

This parser does not check that end tags match start tags or call the end-tag handler for elements which are closed implicitly by closing an outer element.

Changed in version 3.4: *convert_charrefs* keyword argument added.

Changed in version 3.5: The default value for argument *convert_charrefs* is now `True`.

21.2.1 Example HTML Parser Application

As a basic example, below is a simple HTML parser that uses the *HTMLParser* class to print out start tags, end tags, and data as they are encountered:

```
from html.parser import HTMLParser

class MyHTMLParser(HTMLParser):
    def handle_starttag(self, tag, attrs):
        print("Encountered a start tag:", tag)

    def handle_endtag(self, tag):
        print("Encountered an end tag :", tag)

    def handle_data(self, data):
        print("Encountered some data  :", data)

parser = MyHTMLParser()
parser.feed('<html><head><title>Test</title></head>'
            '<body><h1>Parse me!</h1></body></html>')
```

The output will then be:

```
Encountered a start tag: html
Encountered a start tag: head
Encountered a start tag: title
Encountered some data  : Test
Encountered an end tag : title
Encountered an end tag : head
Encountered a start tag: body
Encountered a start tag: h1
Encountered some data  : Parse me!
Encountered an end tag : h1
Encountered an end tag : body
Encountered an end tag : html
```

21.2.2 `HTMLParser` Methods

HTMLParser instances have the following methods:

HTMLParser.**feed**(*data*)
Feed some text to the parser. It is processed insofar as it consists of complete elements; incomplete data is buffered until more data is fed or *close()* is called. *data* must be *str*.

HTMLParser.**close**()
Force processing of all buffered data as if it were followed by an end-of-file mark. This method may be redefined by a derived class to define additional processing at the end of the input, but the redefined version should always call the *HTMLParser* base class method *close()*.

HTMLParser.**reset**()
Reset the instance. Loses all unprocessed data. This is called implicitly at instantiation time.

HTMLParser.**getpos**()
Return current line number and offset.

HTMLParser.**get_starttag_text**()
Return the text of the most recently opened start tag. This should not normally be needed for structured processing, but may be useful in dealing with HTML "as deployed" or for re-generating input with minimal changes (whitespace between attributes can be preserved, etc.).

The following methods are called when data or markup elements are encountered and they are meant to be overridden in a subclass. The base class implementations do nothing (except for *handle_startendtag()*):

HTMLParser.**handle_starttag**(*tag*, *attrs*)
This method is called to handle the start of a tag (e.g. `<div id="main">`).

The *tag* argument is the name of the tag converted to lower case. The *attrs* argument is a list of `(name, value)` pairs containing the attributes found inside the tag's `<>` brackets. The *name* will be translated to lower case, and quotes in the *value* have been removed, and character and entity references have been replaced.

For instance, for the tag `<A HREF="https://www.cwi.nl/">`, this method would be called as `handle_starttag('a', [('href', 'https://www.cwi.nl/')])`.

All entity references from *html.entities* are replaced in the attribute values.

HTMLParser.**handle_endtag**(*tag*)
This method is called to handle the end tag of an element (e.g. `</div>`).

The *tag* argument is the name of the tag converted to lower case.

HTMLParser.**handle_startendtag**(*tag*, *attrs*)
Similar to *handle_starttag()*, but called when the parser encounters an XHTML-style empty tag (`<img ... />`). This method may be overridden by subclasses which require this particular lexical information; the default implementation simply calls *handle_starttag()* and *handle_endtag()*.

HTMLParser.**handle_data**(*data*)
This method is called to process arbitrary data (e.g. text nodes and the content of `<script>...</script>` and `<style>...</style>`).

HTMLParser.**handle_entityref**(*name*)
This method is called to process a named character reference of the form `&name;` (e.g. `&gt;`), where *name* is a general entity reference (e.g. `'gt'`). This method is never called if *convert_charrefs* is `True`.

HTMLParser.**handle_charref**(*name*)
This method is called to process decimal and hexadecimal numeric character references of the form `&#NNN;` and `&#xNNN;`. For example, the decimal equivalent for `&gt;` is `&#62;`, whereas the hexadecimal is `&#x3E;`; in this case the method will receive `'62'` or `'x3E'`. This method is never called if *convert_charrefs* is `True`.

HTMLParser.**handle_comment**(*data*)
This method is called when a comment is encountered (e.g. `<!--comment-->`).

For example, the comment `<!-- comment -->` will cause this method to be called with the argument `' comment '`.

The content of Internet Explorer conditional comments (condcoms) will also be sent to this method, so, for `<!--[if IE 9]>IE9-specific content<![endif]-->`, this method will receive `'[if IE 9]>IE9-specific content<![endif]'`.

`HTMLParser.handle_decl(`*decl*`)`
This method is called to handle an HTML doctype declaration (e.g. `<!DOCTYPE html>`).

The *decl* parameter will be the entire contents of the declaration inside the `<!...>` markup (e.g. `'DOCTYPE html'`).

`HTMLParser.handle_pi(`*data*`)`
Method called when a processing instruction is encountered. The *data* parameter will contain the entire processing instruction. For example, for the processing instruction `<?proc color='red'>`, this method would be called as `handle_pi("proc color='red'")`. It is intended to be overridden by a derived class; the base class implementation does nothing.

Note: The *HTMLParser* class uses the SGML syntactic rules for processing instructions. An XHTML processing instruction using the trailing `'?'` will cause the `'?'` to be included in *data*.

`HTMLParser.unknown_decl(`*data*`)`
This method is called when an unrecognized declaration is read by the parser.

The *data* parameter will be the entire contents of the declaration inside the `<![...]>` markup. It is sometimes useful to be overridden by a derived class. The base class implementation does nothing.

21.2.3 Examples

The following class implements a parser that will be used to illustrate more examples:

```
from html.parser import HTMLParser
from html.entities import name2codepoint

class MyHTMLParser(HTMLParser):
    def handle_starttag(self, tag, attrs):
        print("Start tag:", tag)
        for attr in attrs:
            print("     attr:", attr)

    def handle_endtag(self, tag):
        print("End tag  :", tag)

    def handle_data(self, data):
        print("Data     :", data)

    def handle_comment(self, data):
        print("Comment  :", data)

    def handle_entityref(self, name):
        c = chr(name2codepoint[name])
        print("Named ent:", c)

    def handle_charref(self, name):
        if name.startswith('x'):
            c = chr(int(name[1:], 16))
```

(continues on next page)

(continued from previous page)

```
        else:
            c = chr(int(name))
        print("Num ent  :", c)

    def handle_decl(self, data):
        print("Decl     :", data)

parser = MyHTMLParser()
```

Parsing a doctype:

```
>>> parser.feed('<!DOCTYPE HTML PUBLIC "-//W3C//DTD HTML 4.01//EN" '
...             '"http://www.w3.org/TR/html4/strict.dtd">')
Decl     : DOCTYPE HTML PUBLIC "-//W3C//DTD HTML 4.01//EN" "http://www.w3.org/TR/html4/strict.dtd"
```

Parsing an element with a few attributes and a title:

```
>>> parser.feed('<img src="python-logo.png" alt="The Python logo">')
Start tag: img
     attr: ('src', 'python-logo.png')
     attr: ('alt', 'The Python logo')
>>>
>>> parser.feed('<h1>Python</h1>')
Start tag: h1
Data     : Python
End tag  : h1
```

The content of `script` and `style` elements is returned as is, without further parsing:

```
>>> parser.feed('<style type="text/css">#python { color: green }</style>')
Start tag: style
     attr: ('type', 'text/css')
Data     : #python { color: green }
End tag  : style

>>> parser.feed('<script type="text/javascript">'
...             'alert("<strong>hello!</strong>");</script>')
Start tag: script
     attr: ('type', 'text/javascript')
Data     : alert("<strong>hello!</strong>");
End tag  : script
```

Parsing comments:

```
>>> parser.feed('<!-- a comment -->'
...             '<!--[if IE 9]>IE-specific content<![endif]-->')
Comment  :  a comment
Comment  : [if IE 9]>IE-specific content<![endif]
```

Parsing named and numeric character references and converting them to the correct char (note: these 3 references are all equivalent to `'>'`):

```
>>> parser.feed('&gt;&#62;&#x3E;')
Named ent: >
Num ent  : >
Num ent  : >
```

Feeding incomplete chunks to *feed()* works, but *handle_data()* might be called more than once (unless *convert_charrefs* is set to `True`):

```
>>> for chunk in ['<sp', 'an>buff', 'ered ', 'text</s', 'pan>']:
...     parser.feed(chunk)
...
Start tag: span
Data     : buff
Data     : ered
Data     : text
End tag  : span
```

Parsing invalid HTML (e.g. unquoted attributes) also works:

```
>>> parser.feed('<p><a class=link href=#main>tag soup</p ></a>')
Start tag: p
Start tag: a
     attr: ('class', 'link')
     attr: ('href', '#main')
Data     : tag soup
End tag  : p
End tag  : a
```

21.3 `html.entities` — Definitions of HTML general entities

Source code: Lib/html/entities.py

This module defines four dictionaries, *html5*, *name2codepoint*, *codepoint2name*, and *entitydefs*.

html.entities.html5
A dictionary that maps HTML5 named character references[1] to the equivalent Unicode character(s), e.g. `html5['gt;'] == '>'`. Note that the trailing semicolon is included in the name (e.g. `'gt;'`), however some of the names are accepted by the standard even without the semicolon: in this case the name is present with and without the `';'`. See also *html.unescape()*.

New in version 3.3.

html.entities.entitydefs
A dictionary mapping XHTML 1.0 entity definitions to their replacement text in ISO Latin-1.

html.entities.name2codepoint
A dictionary that maps HTML entity names to the Unicode code points.

html.entities.codepoint2name
A dictionary that maps Unicode code points to HTML entity names.

21.4 XML Processing Modules

Source code: Lib/xml/

Python's interfaces for processing XML are grouped in the `xml` package.

[1] See https://www.w3.org/TR/html5/syntax.html#named-character-references

Warning: The XML modules are not secure against erroneous or maliciously constructed data. If you need to parse untrusted or unauthenticated data see the *XML vulnerabilities* and *The defusedxml and defusedexpat Packages* sections.

It is important to note that modules in the *xml* package require that there be at least one SAX-compliant XML parser available. The Expat parser is included with Python, so the *xml.parsers.expat* module will always be available.

The documentation for the *xml.dom* and *xml.sax* packages are the definition of the Python bindings for the DOM and SAX interfaces.

The XML handling submodules are:

- *xml.etree.ElementTree*: the ElementTree API, a simple and lightweight XML processor
- *xml.dom*: the DOM API definition
- *xml.dom.minidom*: a minimal DOM implementation
- *xml.dom.pulldom*: support for building partial DOM trees
- *xml.sax*: SAX2 base classes and convenience functions
- *xml.parsers.expat*: the Expat parser binding

21.4.1 XML vulnerabilities

The XML processing modules are not secure against maliciously constructed data. An attacker can abuse XML features to carry out denial of service attacks, access local files, generate network connections to other machines, or circumvent firewalls.

The following table gives an overview of the known attacks and whether the various modules are vulnerable to them.

kind	sax	etree	minidom	pulldom	xmlrpc
billion laughs	**Vulnerable**	**Vulnerable**	**Vulnerable**	**Vulnerable**	**Vulnerable**
quadratic blowup	**Vulnerable**	**Vulnerable**	**Vulnerable**	**Vulnerable**	**Vulnerable**
external entity expansion	**Vulnerable**	Safe (1)	Safe (2)	**Vulnerable**	Safe (3)
DTD retrieval	**Vulnerable**	Safe	Safe	**Vulnerable**	Safe
decompression bomb	Safe	Safe	Safe	Safe	**Vulnerable**

1. *xml.etree.ElementTree* doesn't expand external entities and raises a `ParserError` when an entity occurs.
2. *xml.dom.minidom* doesn't expand external entities and simply returns the unexpanded entity verbatim.
3. `xmlrpclib` doesn't expand external entities and omits them.

billion laughs / exponential entity expansion The Billion Laughs attack – also known as exponential entity expansion – uses multiple levels of nested entities. Each entity refers to another entity several times, and the final entity definition contains a small string. The exponential expansion results in several gigabytes of text and consumes lots of memory and CPU time.

quadratic blowup entity expansion A quadratic blowup attack is similar to a Billion Laughs attack; it abuses entity expansion, too. Instead of nested entities it repeats one large entity with a couple of thousand chars over and over again. The attack isn't as efficient as the exponential case but it avoids triggering parser countermeasures that forbid deeply-nested entities.

external entity expansion Entity declarations can contain more than just text for replacement. They can also point to external resources or local files. The XML parser accesses the resource and embeds the content into the XML document.

DTD retrieval Some XML libraries like Python's *xml.dom.pulldom* retrieve document type definitions from remote or local locations. The feature has similar implications as the external entity expansion issue.

decompression bomb Decompression bombs (aka ZIP bomb) apply to all XML libraries that can parse compressed XML streams such as gzipped HTTP streams or LZMA-compressed files. For an attacker it can reduce the amount of transmitted data by three magnitudes or more.

The documentation for defusedxml on PyPI has further information about all known attack vectors with examples and references.

21.4.2 The `defusedxml` and `defusedexpat` Packages

defusedxml is a pure Python package with modified subclasses of all stdlib XML parsers that prevent any potentially malicious operation. Use of this package is recommended for any server code that parses untrusted XML data. The package also ships with example exploits and extended documentation on more XML exploits such as XPath injection.

defusedexpat provides a modified libexpat and a patched `pyexpat` module that have countermeasures against entity expansion DoS attacks. The `defusedexpat` module still allows a sane and configurable amount of entity expansions. The modifications may be included in some future release of Python, but will not be included in any bugfix releases of Python because they break backward compatibility.

21.5 `xml.etree.ElementTree` — The ElementTree XML API

Source code: Lib/xml/etree/ElementTree.py

The *xml.etree.ElementTree* module implements a simple and efficient API for parsing and creating XML data.

Changed in version 3.3: This module will use a fast implementation whenever available. The `xml.etree.cElementTree` module is deprecated.

> **Warning:** The *xml.etree.ElementTree* module is not secure against maliciously constructed data. If you need to parse untrusted or unauthenticated data see *XML vulnerabilities*.

21.5.1 Tutorial

This is a short tutorial for using *xml.etree.ElementTree* (`ET` in short). The goal is to demonstrate some of the building blocks and basic concepts of the module.

XML tree and elements

XML is an inherently hierarchical data format, and the most natural way to represent it is with a tree. `ET` has two classes for this purpose - *ElementTree* represents the whole XML document as a tree, and *Element* represents a single node in this tree. Interactions with the whole document (reading and writing to/from files) are usually done on the *ElementTree* level. Interactions with a single XML element and its sub-elements are done on the *Element* level.

Parsing XML

We'll be using the following XML document as the sample data for this section:

```
<?xml version="1.0"?>
<data>
    <country name="Liechtenstein">
        <rank>1</rank>
        <year>2008</year>
        <gdppc>141100</gdppc>
        <neighbor name="Austria" direction="E"/>
        <neighbor name="Switzerland" direction="W"/>
    </country>
    <country name="Singapore">
        <rank>4</rank>
        <year>2011</year>
        <gdppc>59900</gdppc>
        <neighbor name="Malaysia" direction="N"/>
    </country>
    <country name="Panama">
        <rank>68</rank>
        <year>2011</year>
        <gdppc>13600</gdppc>
        <neighbor name="Costa Rica" direction="W"/>
        <neighbor name="Colombia" direction="E"/>
    </country>
</data>
```

We can import this data by reading from a file:

```
import xml.etree.ElementTree as ET
tree = ET.parse('country_data.xml')
root = tree.getroot()
```

Or directly from a string:

```
root = ET.fromstring(country_data_as_string)
```

fromstring() parses XML from a string directly into an *Element*, which is the root element of the parsed tree. Other parsing functions may create an *ElementTree*. Check the documentation to be sure.

As an *Element*, `root` has a tag and a dictionary of attributes:

```
>>> root.tag
'data'
>>> root.attrib
{}
```

It also has children nodes over which we can iterate:

```
>>> for child in root:
...     print(child.tag, child.attrib)
...
country {'name': 'Liechtenstein'}
country {'name': 'Singapore'}
country {'name': 'Panama'}
```

Children are nested, and we can access specific child nodes by index:

```
>>> root[0][1].text
'2008'
```

Note: Not all elements of the XML input will end up as elements of the parsed tree. Currently, this module skips over any XML comments, processing instructions, and document type declarations in the input. Nevertheless, trees built using this module's API rather than parsing from XML text can have comments and processing instructions in them; they will be included when generating XML output. A document type declaration may be accessed by passing a custom *TreeBuilder* instance to the *XMLParser* constructor.

Pull API for non-blocking parsing

Most parsing functions provided by this module require the whole document to be read at once before returning any result. It is possible to use an *XMLParser* and feed data into it incrementally, but it is a push API that calls methods on a callback target, which is too low-level and inconvenient for most needs. Sometimes what the user really wants is to be able to parse XML incrementally, without blocking operations, while enjoying the convenience of fully constructed *Element* objects.

The most powerful tool for doing this is *XMLPullParser*. It does not require a blocking read to obtain the XML data, and is instead fed with data incrementally with *XMLPullParser.feed()* calls. To get the parsed XML elements, call *XMLPullParser.read_events()*. Here is an example:

```
>>> parser = ET.XMLPullParser(['start', 'end'])
>>> parser.feed('<mytag>sometext')
>>> list(parser.read_events())
[('start', <Element 'mytag' at 0x7fa66db2be58>)]
>>> parser.feed(' more text</mytag>')
>>> for event, elem in parser.read_events():
...     print(event)
...     print(elem.tag, 'text=', elem.text)
...
end
```

The obvious use case is applications that operate in a non-blocking fashion where the XML data is being received from a socket or read incrementally from some storage device. In such cases, blocking reads are unacceptable.

Because it's so flexible, *XMLPullParser* can be inconvenient to use for simpler use-cases. If you don't mind your application blocking on reading XML data but would still like to have incremental parsing capabilities, take a look at *iterparse()*. It can be useful when you're reading a large XML document and don't want to hold it wholly in memory.

Finding interesting elements

Element has some useful methods that help iterate recursively over all the sub-tree below it (its children, their children, and so on). For example, *Element.iter()*:

```
>>> for neighbor in root.iter('neighbor'):
...     print(neighbor.attrib)
...
{'name': 'Austria', 'direction': 'E'}
{'name': 'Switzerland', 'direction': 'W'}
{'name': 'Malaysia', 'direction': 'N'}
```

(continues on next page)

(continued from previous page)

```
{'name': 'Costa Rica', 'direction': 'W'}
{'name': 'Colombia', 'direction': 'E'}
```

Element.findall() finds only elements with a tag which are direct children of the current element. *Element.find()* finds the *first* child with a particular tag, and *Element.text* accesses the element's text content. *Element.get()* accesses the element's attributes:

```
>>> for country in root.findall('country'):
...     rank = country.find('rank').text
...     name = country.get('name')
...     print(name, rank)
...
Liechtenstein 1
Singapore 4
Panama 68
```

More sophisticated specification of which elements to look for is possible by using *XPath*.

Modifying an XML File

ElementTree provides a simple way to build XML documents and write them to files. The *ElementTree.write()* method serves this purpose.

Once created, an *Element* object may be manipulated by directly changing its fields (such as *Element.text*), adding and modifying attributes (*Element.set()* method), as well as adding new children (for example with *Element.append()*).

Let's say we want to add one to each country's rank, and add an `updated` attribute to the rank element:

```
>>> for rank in root.iter('rank'):
...     new_rank = int(rank.text) + 1
...     rank.text = str(new_rank)
...     rank.set('updated', 'yes')
...
>>> tree.write('output.xml')
```

Our XML now looks like this:

```
<?xml version="1.0"?>
<data>
    <country name="Liechtenstein">
        <rank updated="yes">2</rank>
        <year>2008</year>
        <gdppc>141100</gdppc>
        <neighbor name="Austria" direction="E"/>
        <neighbor name="Switzerland" direction="W"/>
    </country>
    <country name="Singapore">
        <rank updated="yes">5</rank>
        <year>2011</year>
        <gdppc>59900</gdppc>
        <neighbor name="Malaysia" direction="N"/>
    </country>
    <country name="Panama">
        <rank updated="yes">69</rank>
        <year>2011</year>
```

(continues on next page)

(continued from previous page)

```
        <gdppc>13600</gdppc>
        <neighbor name="Costa Rica" direction="W"/>
        <neighbor name="Colombia" direction="E"/>
    </country>
</data>
```

We can remove elements using *Element.remove()*. Let's say we want to remove all countries with a rank higher than 50:

```
>>> for country in root.findall('country'):
...     rank = int(country.find('rank').text)
...     if rank > 50:
...         root.remove(country)
...
>>> tree.write('output.xml')
```

Our XML now looks like this:

```
<?xml version="1.0"?>
<data>
    <country name="Liechtenstein">
        <rank updated="yes">2</rank>
        <year>2008</year>
        <gdppc>141100</gdppc>
        <neighbor name="Austria" direction="E"/>
        <neighbor name="Switzerland" direction="W"/>
    </country>
    <country name="Singapore">
        <rank updated="yes">5</rank>
        <year>2011</year>
        <gdppc>59900</gdppc>
        <neighbor name="Malaysia" direction="N"/>
    </country>
</data>
```

Building XML documents

The *SubElement()* function also provides a convenient way to create new sub-elements for a given element:

```
>>> a = ET.Element('a')
>>> b = ET.SubElement(a, 'b')
>>> c = ET.SubElement(a, 'c')
>>> d = ET.SubElement(c, 'd')
>>> ET.dump(a)
<a><b /><c><d /></c></a>
```

Parsing XML with Namespaces

If the XML input has namespaces, tags and attributes with prefixes in the form `prefix:sometag` get expanded to `{uri}sometag` where the *prefix* is replaced by the full *URI*. Also, if there is a default namespace, that full URI gets prepended to all of the non-prefixed tags.

Here is an XML example that incorporates two namespaces, one with the prefix "fictional" and the other serving as the default namespace:

```
<?xml version="1.0"?>
<actors xmlns:fictional="http://characters.example.com"
        xmlns="http://people.example.com">
    <actor>
        <name>John Cleese</name>
        <fictional:character>Lancelot</fictional:character>
        <fictional:character>Archie Leach</fictional:character>
    </actor>
    <actor>
        <name>Eric Idle</name>
        <fictional:character>Sir Robin</fictional:character>
        <fictional:character>Gunther</fictional:character>
        <fictional:character>Commander Clement</fictional:character>
    </actor>
</actors>
```

One way to search and explore this XML example is to manually add the URI to every tag or attribute in the xpath of a *find()* or *findall()*:

```
root = fromstring(xml_text)
for actor in root.findall('{http://people.example.com}actor'):
    name = actor.find('{http://people.example.com}name')
    print(name.text)
    for char in actor.findall('{http://characters.example.com}character'):
        print(' |-->', char.text)
```

A better way to search the namespaced XML example is to create a dictionary with your own prefixes and use those in the search functions:

```
ns = {'real_person': 'http://people.example.com',
      'role': 'http://characters.example.com'}

for actor in root.findall('real_person:actor', ns):
    name = actor.find('real_person:name', ns)
    print(name.text)
    for char in actor.findall('role:character', ns):
        print(' |-->', char.text)
```

These two approaches both output:

```
John Cleese
 |--> Lancelot
 |--> Archie Leach
Eric Idle
 |--> Sir Robin
 |--> Gunther
 |--> Commander Clement
```

Additional resources

See http://effbot.org/zone/element-index.htm for tutorials and links to other docs.

21.5.2 XPath support

This module provides limited support for XPath expressions for locating elements in a tree. The goal is to support a small subset of the abbreviated syntax; a full XPath engine is outside the scope of the module.

Example

Here's an example that demonstrates some of the XPath capabilities of the module. We'll be using the `countrydata` XML document from the *Parsing XML* section:

```
import xml.etree.ElementTree as ET

root = ET.fromstring(countrydata)

# Top-level elements
root.findall(".")

# All 'neighbor' grand-children of 'country' children of the top-level
# elements
root.findall("./country/neighbor")

# Nodes with name='Singapore' that have a 'year' child
root.findall(".//year/..[@name='Singapore']")

# 'year' nodes that are children of nodes with name='Singapore'
root.findall(".//*[@name='Singapore']/year")

# All 'neighbor' nodes that are the second child of their parent
root.findall(".//neighbor[2]")
```

Supported XPath syntax

Syntax	Meaning
`tag`	Selects all child elements with the given tag. For example, `spam` selects all child elements named `spam`, and `spam/egg` selects all grandchildren named `egg` in all children named `spam`.
`*`	Selects all child elements. For example, `*/egg` selects all grandchildren named `egg`.
`.`	Selects the current node. This is mostly useful at the beginning of the path, to indicate that it's a relative path.
`//`	Selects all subelements, on all levels beneath the current element. For example, `.//egg` selects all `egg` elements in the entire tree.
`..`	Selects the parent element. Returns `None` if the path attempts to reach the ancestors of the start element (the element `find` was called on).
`[@attrib]`	Selects all elements that have the given attribute.
`[@attrib='value']`	Selects all elements for which the given attribute has the given value. The value cannot contain quotes.
`[tag]`	Selects all elements that have a child named `tag`. Only immediate children are supported.
`[.='text']`	Selects all elements whose complete text content, including descendants, equals the given `text`. New in version 3.7.
`[tag='text']`	Selects all elements that have a child named `tag` whose complete text content, including descendants, equals the given `text`.
`[position]`	Selects all elements that are located at the given position. The position can be either an integer (1 is the first position), the expression `last()` (for the last position), or a position relative to the last position (e.g. `last()-1`).

Predicates (expressions within square brackets) must be preceded by a tag name, an asterisk, or another

predicate. `position` predicates must be preceded by a tag name.

21.5.3 Reference

Functions

`xml.etree.ElementTree.Comment`(*text=None*)
Comment element factory. This factory function creates a special element that will be serialized as an XML comment by the standard serializer. The comment string can be either a bytestring or a Unicode string. *text* is a string containing the comment string. Returns an element instance representing a comment.

Note that *XMLParser* skips over comments in the input instead of creating comment objects for them. An *ElementTree* will only contain comment nodes if they have been inserted into to the tree using one of the *Element* methods.

`xml.etree.ElementTree.dump`(*elem*)
Writes an element tree or element structure to sys.stdout. This function should be used for debugging only.

The exact output format is implementation dependent. In this version, it's written as an ordinary XML file.

elem is an element tree or an individual element.

`xml.etree.ElementTree.fromstring`(*text*)
Parses an XML section from a string constant. Same as *XML()*. *text* is a string containing XML data. Returns an *Element* instance.

`xml.etree.ElementTree.fromstringlist`(*sequence*, *parser=None*)
Parses an XML document from a sequence of string fragments. *sequence* is a list or other sequence containing XML data fragments. *parser* is an optional parser instance. If not given, the standard *XMLParser* parser is used. Returns an *Element* instance.

New in version 3.2.

`xml.etree.ElementTree.iselement`(*element*)
Checks if an object appears to be a valid element object. *element* is an element instance. Returns a true value if this is an element object.

`xml.etree.ElementTree.iterparse`(*source*, *events=None*, *parser=None*)
Parses an XML section into an element tree incrementally, and reports what's going on to the user. *source* is a filename or *file object* containing XML data. *events* is a sequence of events to report back. The supported events are the strings `"start"`, `"end"`, `"start-ns"` and `"end-ns"` (the "ns" events are used to get detailed namespace information). If *events* is omitted, only `"end"` events are reported. *parser* is an optional parser instance. If not given, the standard *XMLParser* parser is used. *parser* must be a subclass of *XMLParser* and can only use the default *TreeBuilder* as a target. Returns an *iterator* providing `(event, elem)` pairs.

Note that while *iterparse()* builds the tree incrementally, it issues blocking reads on *source* (or the file it names). As such, it's unsuitable for applications where blocking reads can't be made. For fully non-blocking parsing, see *XMLPullParser*.

Note: *iterparse()* only guarantees that it has seen the ">" character of a starting tag when it emits a "start" event, so the attributes are defined, but the contents of the text and tail attributes are undefined at that point. The same applies to the element children; they may or may not be present.

If you need a fully populated element, look for "end" events instead.

Deprecated since version 3.4: The *parser* argument.

xml.etree.ElementTree.**parse**(*source*, *parser=None*)
Parses an XML section into an element tree. *source* is a filename or file object containing XML data. *parser* is an optional parser instance. If not given, the standard *XMLParser* parser is used. Returns an *ElementTree* instance.

xml.etree.ElementTree.**ProcessingInstruction**(*target*, *text=None*)
PI element factory. This factory function creates a special element that will be serialized as an XML processing instruction. *target* is a string containing the PI target. *text* is a string containing the PI contents, if given. Returns an element instance, representing a processing instruction.

Note that *XMLParser* skips over processing instructions in the input instead of creating comment objects for them. An *ElementTree* will only contain processing instruction nodes if they have been inserted into to the tree using one of the *Element* methods.

xml.etree.ElementTree.**register_namespace**(*prefix*, *uri*)
Registers a namespace prefix. The registry is global, and any existing mapping for either the given prefix or the namespace URI will be removed. *prefix* is a namespace prefix. *uri* is a namespace uri. Tags and attributes in this namespace will be serialized with the given prefix, if at all possible.

New in version 3.2.

xml.etree.ElementTree.**SubElement**(*parent*, *tag*, *attrib={}*, ***extra*)
Subelement factory. This function creates an element instance, and appends it to an existing element.

The element name, attribute names, and attribute values can be either bytestrings or Unicode strings. *parent* is the parent element. *tag* is the subelement name. *attrib* is an optional dictionary, containing element attributes. *extra* contains additional attributes, given as keyword arguments. Returns an element instance.

xml.etree.ElementTree.**tostring**(*element*, *encoding="us-ascii"*, *method="xml"*, ***, *short_empty_elements=True*)
Generates a string representation of an XML element, including all subelements. *element* is an *Element* instance. *encoding*[1] is the output encoding (default is US-ASCII). Use `encoding="unicode"` to generate a Unicode string (otherwise, a bytestring is generated). *method* is either `"xml"`, `"html"` or `"text"` (default is `"xml"`). *short_empty_elements* has the same meaning as in *ElementTree.write()*. Returns an (optionally) encoded string containing the XML data.

New in version 3.4: The *short_empty_elements* parameter.

xml.etree.ElementTree.**tostringlist**(*element*, *encoding="us-ascii"*, *method="xml"*, ***, *short_empty_elements=True*)
Generates a string representation of an XML element, including all subelements. *element* is an *Element* instance. *encoding*[1] is the output encoding (default is US-ASCII). Use `encoding="unicode"` to generate a Unicode string (otherwise, a bytestring is generated). *method* is either `"xml"`, `"html"` or `"text"` (default is `"xml"`). *short_empty_elements* has the same meaning as in *ElementTree.write()*. Returns a list of (optionally) encoded strings containing the XML data. It does not guarantee any specific sequence, except that `b"".join(tostringlist(element)) == tostring(element)`.

New in version 3.2.

New in version 3.4: The *short_empty_elements* parameter.

xml.etree.ElementTree.**XML**(*text*, *parser=None*)
Parses an XML section from a string constant. This function can be used to embed "XML literals" in Python code. *text* is a string containing XML data. *parser* is an optional parser instance. If not given, the standard *XMLParser* parser is used. Returns an *Element* instance.

[1] The encoding string included in XML output should conform to the appropriate standards. For example, "UTF-8" is valid, but "UTF8" is not. See https://www.w3.org/TR/2006/REC-xml11-20060816/#NT-EncodingDecl and https://www.iana.org/assignments/character-sets/character-sets.xhtml.

xml.etree.ElementTree.**XMLID**(*text*, *parser=None*)
Parses an XML section from a string constant, and also returns a dictionary which maps from element id:s to elements. *text* is a string containing XML data. *parser* is an optional parser instance. If not given, the standard *XMLParser* parser is used. Returns a tuple containing an *Element* instance and a dictionary.

Element Objects

class xml.etree.ElementTree.**Element**(*tag*, *attrib={}*, ***extra*)
Element class. This class defines the Element interface, and provides a reference implementation of this interface.

The element name, attribute names, and attribute values can be either bytestrings or Unicode strings. *tag* is the element name. *attrib* is an optional dictionary, containing element attributes. *extra* contains additional attributes, given as keyword arguments.

tag
A string identifying what kind of data this element represents (the element type, in other words).

text
tail
These attributes can be used to hold additional data associated with the element. Their values are usually strings but may be any application-specific object. If the element is created from an XML file, the *text* attribute holds either the text between the element's start tag and its first child or end tag, or `None`, and the *tail* attribute holds either the text between the element's end tag and the next tag, or `None`. For the XML data

```
<a><b>1<c>2<d/>3</c></b>4</a>
```

the *a* element has `None` for both *text* and *tail* attributes, the *b* element has *text* `"1"` and *tail* `"4"`, the *c* element has *text* `"2"` and *tail* `None`, and the *d* element has *text* `None` and *tail* `"3"`.

To collect the inner text of an element, see *itertext()*, for example `"".join(element.itertext())`.

Applications may store arbitrary objects in these attributes.

attrib
A dictionary containing the element's attributes. Note that while the *attrib* value is always a real mutable Python dictionary, an ElementTree implementation may choose to use another internal representation, and create the dictionary only if someone asks for it. To take advantage of such implementations, use the dictionary methods below whenever possible.

The following dictionary-like methods work on the element attributes.

clear()
Resets an element. This function removes all subelements, clears all attributes, and sets the text and tail attributes to `None`.

get(*key*, *default=None*)
Gets the element attribute named *key*.

Returns the attribute value, or *default* if the attribute was not found.

items()
Returns the element attributes as a sequence of (name, value) pairs. The attributes are returned in an arbitrary order.

keys()
Returns the elements attribute names as a list. The names are returned in an arbitrary order.

set(*key*, *value*)
Set the attribute *key* on the element to *value*.

The following methods work on the element's children (subelements).

append(*subelement*)
Adds the element *subelement* to the end of this element's internal list of subelements. Raises *TypeError* if *subelement* is not an *Element*.

extend(*subelements*)
Appends *subelements* from a sequence object with zero or more elements. Raises *TypeError* if a subelement is not an *Element*.

New in version 3.2.

find(*match*, *namespaces=None*)
Finds the first subelement matching *match*. *match* may be a tag name or a *path*. Returns an element instance or `None`. *namespaces* is an optional mapping from namespace prefix to full name.

findall(*match*, *namespaces=None*)
Finds all matching subelements, by tag name or *path*. Returns a list containing all matching elements in document order. *namespaces* is an optional mapping from namespace prefix to full name.

findtext(*match*, *default=None*, *namespaces=None*)
Finds text for the first subelement matching *match*. *match* may be a tag name or a *path*. Returns the text content of the first matching element, or *default* if no element was found. Note that if the matching element has no text content an empty string is returned. *namespaces* is an optional mapping from namespace prefix to full name.

getchildren()
Deprecated since version 3.2: Use `list(elem)` or iteration.

getiterator(*tag=None*)
Deprecated since version 3.2: Use method *Element.iter()* instead.

insert(*index*, *subelement*)
Inserts *subelement* at the given position in this element. Raises *TypeError* if *subelement* is not an *Element*.

iter(*tag=None*)
Creates a tree *iterator* with the current element as the root. The iterator iterates over this element and all elements below it, in document (depth first) order. If *tag* is not `None` or `'*'`, only elements whose tag equals *tag* are returned from the iterator. If the tree structure is modified during iteration, the result is undefined.

New in version 3.2.

iterfind(*match*, *namespaces=None*)
Finds all matching subelements, by tag name or *path*. Returns an iterable yielding all matching elements in document order. *namespaces* is an optional mapping from namespace prefix to full name.

New in version 3.2.

itertext()
Creates a text iterator. The iterator loops over this element and all subelements, in document order, and returns all inner text.

New in version 3.2.

makeelement(*tag*, *attrib*)
Creates a new element object of the same type as this element. Do not call this method, use the *SubElement()* factory function instead.

remove(*subelement*)
Removes *subelement* from the element. Unlike the find* methods this method compares elements based on the instance identity, not on tag value or contents.

Element objects also support the following sequence type methods for working with subelements: `__delitem__()`, `__getitem__()`, `__setitem__()`, `__len__()`.

Caution: Elements with no subelements will test as `False`. This behavior will change in future versions. Use specific `len(elem)` or `elem is None` test instead.

```
element = root.find('foo')

if not element:  # careful!
    print("element not found, or element has no subelements")

if element is None:
    print("element not found")
```

ElementTree Objects

class xml.etree.ElementTree.**ElementTree**(*element=None*, *file=None*)
ElementTree wrapper class. This class represents an entire element hierarchy, and adds some extra support for serialization to and from standard XML.

element is the root element. The tree is initialized with the contents of the XML *file* if given.

_setroot(*element*)
Replaces the root element for this tree. This discards the current contents of the tree, and replaces it with the given element. Use with care. *element* is an element instance.

find(*match*, *namespaces=None*)
Same as *Element.find()*, starting at the root of the tree.

findall(*match*, *namespaces=None*)
Same as *Element.findall()*, starting at the root of the tree.

findtext(*match*, *default=None*, *namespaces=None*)
Same as *Element.findtext()*, starting at the root of the tree.

getiterator(*tag=None*)
Deprecated since version 3.2: Use method *ElementTree.iter()* instead.

getroot()
Returns the root element for this tree.

iter(*tag=None*)
Creates and returns a tree iterator for the root element. The iterator loops over all elements in this tree, in section order. *tag* is the tag to look for (default is to return all elements).

iterfind(*match*, *namespaces=None*)
Same as *Element.iterfind()*, starting at the root of the tree.

New in version 3.2.

parse(*source*, *parser=None*)
Loads an external XML section into this element tree. *source* is a file name or *file object*. *parser* is an optional parser instance. If not given, the standard *XMLParser* parser is used. Returns the section root element.

write(*file*, *encoding="us-ascii"*, *xml_declaration=None*, *default_namespace=None*, *method="xml"*, ***, *short_empty_elements=True*)
Writes the element tree to a file, as XML. *file* is a file name, or a *file object* opened for writing.

encoding[1] is the output encoding (default is US-ASCII). *xml_declaration* controls if an XML declaration should be added to the file. Use `False` for never, `True` for always, `None` for only if not US-ASCII or UTF-8 or Unicode (default is `None`). *default_namespace* sets the default XML namespace (for "xmlns"). *method* is either `"xml"`, `"html"` or `"text"` (default is `"xml"`). The keyword-only *short_empty_elements* parameter controls the formatting of elements that contain no content. If `True` (the default), they are emitted as a single self-closed tag, otherwise they are emitted as a pair of start/end tags.

The output is either a string (*str*) or binary (*bytes*). This is controlled by the *encoding* argument. If *encoding* is `"unicode"`, the output is a string; otherwise, it's binary. Note that this may conflict with the type of *file* if it's an open *file object*; make sure you do not try to write a string to a binary stream and vice versa.

New in version 3.4: The *short_empty_elements* parameter.

This is the XML file that is going to be manipulated:

```
<html>
    <head>
        <title>Example page</title>
    </head>
    <body>
        <p>Moved to <a href="http://example.org/">example.org</a>
        or <a href="http://example.com/">example.com</a>.</p>
    </body>
</html>
```

Example of changing the attribute "target" of every link in first paragraph:

```
>>> from xml.etree.ElementTree import ElementTree
>>> tree = ElementTree()
>>> tree.parse("index.xhtml")
<Element 'html' at 0xb77e6fac>
>>> p = tree.find("body/p")     # Finds first occurrence of tag p in body
>>> p
<Element 'p' at 0xb77ec26c>
>>> links = list(p.iter("a"))   # Returns list of all links
>>> links
[<Element 'a' at 0xb77ec2ac>, <Element 'a' at 0xb77ec1cc>]
>>> for i in links:             # Iterates through all found links
...     i.attrib["target"] = "blank"
>>> tree.write("output.xhtml")
```

QName Objects

class xml.etree.ElementTree.**QName**(*text_or_uri*, *tag=None*)

QName wrapper. This can be used to wrap a QName attribute value, in order to get proper namespace handling on output. *text_or_uri* is a string containing the QName value, in the form {uri}local, or, if the tag argument is given, the URI part of a QName. If *tag* is given, the first argument is interpreted as a URI, and this argument is interpreted as a local name. *QName* instances are opaque.

TreeBuilder Objects

class xml.etree.ElementTree.**TreeBuilder**(*element_factory=None*)

Generic element structure builder. This builder converts a sequence of start, data, and end method calls to a well-formed element structure. You can use this class to build an element structure using a

custom XML parser, or a parser for some other XML-like format. *element_factory*, when given, must be a callable accepting two positional arguments: a tag and a dict of attributes. It is expected to return a new element instance.

close()
Flushes the builder buffers, and returns the toplevel document element. Returns an *Element* instance.

data(*data*)
Adds text to the current element. *data* is a string. This should be either a bytestring, or a Unicode string.

end(*tag*)
Closes the current element. *tag* is the element name. Returns the closed element.

start(*tag*, *attrs*)
Opens a new element. *tag* is the element name. *attrs* is a dictionary containing element attributes. Returns the opened element.

In addition, a custom *TreeBuilder* object can provide the following method:

doctype(*name*, *pubid*, *system*)
Handles a doctype declaration. *name* is the doctype name. *pubid* is the public identifier. *system* is the system identifier. This method does not exist on the default *TreeBuilder* class.

New in version 3.2.

XMLParser Objects

class xml.etree.ElementTree.**XMLParser**(*html=0*, *target=None*, *encoding=None*)
This class is the low-level building block of the module. It uses *xml.parsers.expat* for efficient, event-based parsing of XML. It can be fed XML data incrementally with the *feed()* method, and parsing events are translated to a push API - by invoking callbacks on the *target* object. If *target* is omitted, the standard *TreeBuilder* is used. The *html* argument was historically used for backwards compatibility and is now deprecated. If *encoding*[1] is given, the value overrides the encoding specified in the XML file.

Deprecated since version 3.4: The *html* argument. The remaining arguments should be passed via keyword to prepare for the removal of the *html* argument.

close()
Finishes feeding data to the parser. Returns the result of calling the `close()` method of the *target* passed during construction; by default, this is the toplevel document element.

doctype(*name*, *pubid*, *system*)
Deprecated since version 3.2: Define the *TreeBuilder.doctype()* method on a custom TreeBuilder target.

feed(*data*)
Feeds data to the parser. *data* is encoded data.

XMLParser.feed() calls *target*'s `start(tag, attrs_dict)` method for each opening tag, its `end(tag)` method for each closing tag, and data is processed by method `data(data)`. *XMLParser.close()* calls *target*'s method `close()`. *XMLParser* can be used not only for building a tree structure. This is an example of counting the maximum depth of an XML file:

```
>>> from xml.etree.ElementTree import XMLParser
>>> class MaxDepth:                     # The target object of the parser
...     maxDepth = 0
...     depth = 0
```

(continues on next page)

(continued from previous page)

```
...     def start(self, tag, attrib):   # Called for each opening tag.
...         self.depth += 1
...         if self.depth > self.maxDepth:
...             self.maxDepth = self.depth
...     def end(self, tag):             # Called for each closing tag.
...         self.depth -= 1
...     def data(self, data):
...         pass            # We do not need to do anything with data.
...     def close(self):    # Called when all data has been parsed.
...         return self.maxDepth
...
>>> target = MaxDepth()
>>> parser = XMLParser(target=target)
>>> exampleXml = """
... <a>
...   <b>
...   </b>
...   <b>
...     <c>
...       <d>
...       </d>
...     </c>
...   </b>
... </a>"""
>>> parser.feed(exampleXml)
>>> parser.close()
4
```

XMLPullParser Objects

class xml.etree.ElementTree.**XMLPullParser**(*events=None*)

A pull parser suitable for non-blocking applications. Its input-side API is similar to that of *XMLParser*, but instead of pushing calls to a callback target, *XMLPullParser* collects an internal list of parsing events and lets the user read from it. *events* is a sequence of events to report back. The supported events are the strings `"start"`, `"end"`, `"start-ns"` and `"end-ns"` (the "ns" events are used to get detailed namespace information). If *events* is omitted, only `"end"` events are reported.

feed(*data*)

Feed the given bytes data to the parser.

close()

Signal the parser that the data stream is terminated. Unlike *XMLParser.close()*, this method always returns *None*. Any events not yet retrieved when the parser is closed can still be read with *read_events()*.

read_events()

Return an iterator over the events which have been encountered in the data fed to the parser. The iterator yields `(event, elem)` pairs, where *event* is a string representing the type of event (e.g. `"end"`) and *elem* is the encountered *Element* object.

Events provided in a previous call to *read_events()* will not be yielded again. Events are consumed from the internal queue only when they are retrieved from the iterator, so multiple readers iterating in parallel over iterators obtained from *read_events()* will have unpredictable results.

Note: *XMLPullParser* only guarantees that it has seen the ">" character of a starting tag when it emits a "start" event, so the attributes are defined, but the contents of the text and tail attributes are undefined at that point. The same applies to the element children; they may or may not be present.

If you need a fully populated element, look for "end" events instead.

New in version 3.4.

Exceptions

`class xml.etree.ElementTree.ParseError`
XML parse error, raised by the various parsing methods in this module when parsing fails. The string representation of an instance of this exception will contain a user-friendly error message. In addition, it will have the following attributes available:

`code`
A numeric error code from the expat parser. See the documentation of *xml.parsers.expat* for the list of error codes and their meanings.

`position`
A tuple of *line*, *column* numbers, specifying where the error occurred.

21.6 `xml.dom` — The Document Object Model API

Source code: Lib/xml/dom/__init__.py

The Document Object Model, or "DOM," is a cross-language API from the World Wide Web Consortium (W3C) for accessing and modifying XML documents. A DOM implementation presents an XML document as a tree structure, or allows client code to build such a structure from scratch. It then gives access to the structure through a set of objects which provided well-known interfaces.

The DOM is extremely useful for random-access applications. SAX only allows you a view of one bit of the document at a time. If you are looking at one SAX element, you have no access to another. If you are looking at a text node, you have no access to a containing element. When you write a SAX application, you need to keep track of your program's position in the document somewhere in your own code. SAX does not do it for you. Also, if you need to look ahead in the XML document, you are just out of luck.

Some applications are simply impossible in an event driven model with no access to a tree. Of course you could build some sort of tree yourself in SAX events, but the DOM allows you to avoid writing that code. The DOM is a standard tree representation for XML data.

The Document Object Model is being defined by the W3C in stages, or "levels" in their terminology. The Python mapping of the API is substantially based on the DOM Level 2 recommendation.

DOM applications typically start by parsing some XML into a DOM. How this is accomplished is not covered at all by DOM Level 1, and Level 2 provides only limited improvements: There is a `DOMImplementation` object class which provides access to `Document` creation methods, but no way to access an XML reader/parser/Document builder in an implementation-independent way. There is also no well-defined way to access these methods without an existing `Document` object. In Python, each DOM implementation will provide a function *getDOMImplementation()*. DOM Level 3 adds a Load/Store specification, which defines an interface to the reader, but this is not yet available in the Python standard library.

Once you have a DOM document object, you can access the parts of your XML document through its properties and methods. These properties are defined in the DOM specification; this portion of the reference manual describes the interpretation of the specification in Python.

The specification provided by the W3C defines the DOM API for Java, ECMAScript, and OMG IDL. The Python mapping defined here is based in large part on the IDL version of the specification, but strict compliance is not required (though implementations are free to support the strict mapping from IDL). See section *Conformance* for a detailed discussion of mapping requirements.

See also:

Document Object Model (DOM) Level 2 Specification The W3C recommendation upon which the Python DOM API is based.

Document Object Model (DOM) Level 1 Specification The W3C recommendation for the DOM supported by *xml.dom.minidom*.

Python Language Mapping Specification This specifies the mapping from OMG IDL to Python.

21.6.1 Module Contents

The *xml.dom* contains the following functions:

`xml.dom.registerDOMImplementation`(*name*, *factory*)
Register the *factory* function with the name *name*. The factory function should return an object which implements the `DOMImplementation` interface. The factory function can return the same object every time, or a new one for each call, as appropriate for the specific implementation (e.g. if that implementation supports some customization).

`xml.dom.getDOMImplementation`(*name=None*, *features=()*)
Return a suitable DOM implementation. The *name* is either well-known, the module name of a DOM implementation, or `None`. If it is not `None`, imports the corresponding module and returns a `DOMImplementation` object if the import succeeds. If no name is given, and if the environment variable `PYTHON_DOM` is set, this variable is used to find the implementation.

If name is not given, this examines the available implementations to find one with the required feature set. If no implementation can be found, raise an *ImportError*. The features list must be a sequence of `(feature, version)` pairs which are passed to the `hasFeature()` method on available `DOMImplementation` objects.

Some convenience constants are also provided:

`xml.dom.EMPTY_NAMESPACE`
The value used to indicate that no namespace is associated with a node in the DOM. This is typically found as the `namespaceURI` of a node, or used as the *namespaceURI* parameter to a namespaces-specific method.

`xml.dom.XML_NAMESPACE`
The namespace URI associated with the reserved prefix `xml`, as defined by Namespaces in XML (section 4).

`xml.dom.XMLNS_NAMESPACE`
The namespace URI for namespace declarations, as defined by Document Object Model (DOM) Level 2 Core Specification (section 1.1.8).

`xml.dom.XHTML_NAMESPACE`
The URI of the XHTML namespace as defined by XHTML 1.0: The Extensible HyperText Markup Language (section 3.1.1).

In addition, *xml.dom* contains a base `Node` class and the DOM exception classes. The `Node` class provided by this module does not implement any of the methods or attributes defined by the DOM specification;

concrete DOM implementations must provide those. The `Node` class provided as part of this module does provide the constants used for the `nodeType` attribute on concrete `Node` objects; they are located within the class rather than at the module level to conform with the DOM specifications.

21.6.2 Objects in the DOM

The definitive documentation for the DOM is the DOM specification from the W3C.

Note that DOM attributes may also be manipulated as nodes instead of as simple strings. It is fairly rare that you must do this, however, so this usage is not yet documented.

Interface	Section	Purpose
`DOMImplementation`	*DOMImplementation Objects*	Interface to the underlying implementation.
`Node`	*Node Objects*	Base interface for most objects in a document.
`NodeList`	*NodeList Objects*	Interface for a sequence of nodes.
`DocumentType`	*DocumentType Objects*	Information about the declarations needed to process a document.
`Document`	*Document Objects*	Object which represents an entire document.
`Element`	*Element Objects*	Element nodes in the document hierarchy.
`Attr`	*Attr Objects*	Attribute value nodes on element nodes.
`Comment`	*Comment Objects*	Representation of comments in the source document.
`Text`	*Text and CDATASection Objects*	Nodes containing textual content from the document.
`ProcessingInstruction`	*ProcessingInstruction Objects*	Processing instruction representation.

An additional section describes the exceptions defined for working with the DOM in Python.

DOMImplementation Objects

The `DOMImplementation` interface provides a way for applications to determine the availability of particular features in the DOM they are using. DOM Level 2 added the ability to create new `Document` and `DocumentType` objects using the `DOMImplementation` as well.

`DOMImplementation.hasFeature(`*feature*, *version*`)`
Return true if the feature identified by the pair of strings *feature* and *version* is implemented.

`DOMImplementation.createDocument(`*namespaceUri*, *qualifiedName*, *doctype*`)`
Return a new `Document` object (the root of the DOM), with a child `Element` object having the given *namespaceUri* and *qualifiedName*. The *doctype* must be a `DocumentType` object created by *createDocumentType()*, or `None`. In the Python DOM API, the first two arguments can also be `None` in order to indicate that no `Element` child is to be created.

`DOMImplementation.createDocumentType(`*qualifiedName*, *publicId*, *systemId*`)`
Return a new `DocumentType` object that encapsulates the given *qualifiedName*, *publicId*, and *systemId* strings, representing the information contained in an XML document type declaration.

Node Objects

All of the components of an XML document are subclasses of `Node`.

`Node.nodeType`
An integer representing the node type. Symbolic constants for the types are on the `Node`

object: ELEMENT_NODE, ATTRIBUTE_NODE, TEXT_NODE, CDATA_SECTION_NODE, ENTITY_NODE, PROCESSING_INSTRUCTION_NODE, COMMENT_NODE, DOCUMENT_NODE, DOCUMENT_TYPE_NODE, NOTATION_NODE. This is a read-only attribute.

Node.**parentNode**
The parent of the current node, or None for the document node. The value is always a Node object or None. For Element nodes, this will be the parent element, except for the root element, in which case it will be the Document object. For Attr nodes, this is always None. This is a read-only attribute.

Node.**attributes**
A NamedNodeMap of attribute objects. Only elements have actual values for this; others provide None for this attribute. This is a read-only attribute.

Node.**previousSibling**
The node that immediately precedes this one with the same parent. For instance the element with an end-tag that comes just before the *self* element's start-tag. Of course, XML documents are made up of more than just elements so the previous sibling could be text, a comment, or something else. If this node is the first child of the parent, this attribute will be None. This is a read-only attribute.

Node.**nextSibling**
The node that immediately follows this one with the same parent. See also *previousSibling*. If this is the last child of the parent, this attribute will be None. This is a read-only attribute.

Node.**childNodes**
A list of nodes contained within this node. This is a read-only attribute.

Node.**firstChild**
The first child of the node, if there are any, or None. This is a read-only attribute.

Node.**lastChild**
The last child of the node, if there are any, or None. This is a read-only attribute.

Node.**localName**
The part of the tagName following the colon if there is one, else the entire tagName. The value is a string.

Node.**prefix**
The part of the tagName preceding the colon if there is one, else the empty string. The value is a string, or None.

Node.**namespaceURI**
The namespace associated with the element name. This will be a string or None. This is a read-only attribute.

Node.**nodeName**
This has a different meaning for each node type; see the DOM specification for details. You can always get the information you would get here from another property such as the tagName property for elements or the name property for attributes. For all node types, the value of this attribute will be either a string or None. This is a read-only attribute.

Node.**nodeValue**
This has a different meaning for each node type; see the DOM specification for details. The situation is similar to that with *nodeName*. The value is a string or None.

Node.**hasAttributes**()
Returns true if the node has any attributes.

Node.**hasChildNodes**()
Returns true if the node has any child nodes.

Node.**isSameNode**(*other*)
Returns true if *other* refers to the same node as this node. This is especially useful for DOM imple-

mentations which use any sort of proxy architecture (because more than one object can refer to the same node).

Note: This is based on a proposed DOM Level 3 API which is still in the "working draft" stage, but this particular interface appears uncontroversial. Changes from the W3C will not necessarily affect this method in the Python DOM interface (though any new W3C API for this would also be supported).

`Node.appendChild(`*newChild*`)`
Add a new child node to this node at the end of the list of children, returning *newChild*. If the node was already in the tree, it is removed first.

`Node.insertBefore(`*newChild*, *refChild*`)`
Insert a new child node before an existing child. It must be the case that *refChild* is a child of this node; if not, *ValueError* is raised. *newChild* is returned. If *refChild* is `None`, it inserts *newChild* at the end of the children's list.

`Node.removeChild(`*oldChild*`)`
Remove a child node. *oldChild* must be a child of this node; if not, *ValueError* is raised. *oldChild* is returned on success. If *oldChild* will not be used further, its `unlink()` method should be called.

`Node.replaceChild(`*newChild*, *oldChild*`)`
Replace an existing node with a new node. It must be the case that *oldChild* is a child of this node; if not, *ValueError* is raised.

`Node.normalize()`
Join adjacent text nodes so that all stretches of text are stored as single `Text` instances. This simplifies processing text from a DOM tree for many applications.

`Node.cloneNode(`*deep*`)`
Clone this node. Setting *deep* means to clone all child nodes as well. This returns the clone.

NodeList Objects

A `NodeList` represents a sequence of nodes. These objects are used in two ways in the DOM Core recommendation: an `Element` object provides one as its list of child nodes, and the `getElementsByTagName()` and `getElementsByTagNameNS()` methods of `Node` return objects with this interface to represent query results.

The DOM Level 2 recommendation defines one method and one attribute for these objects:

`NodeList.item(`*i*`)`
Return the *i*'th item from the sequence, if there is one, or `None`. The index *i* is not allowed to be less than zero or greater than or equal to the length of the sequence.

`NodeList.length`
The number of nodes in the sequence.

In addition, the Python DOM interface requires that some additional support is provided to allow `NodeList` objects to be used as Python sequences. All `NodeList` implementations must include support for `__len__()` and `__getitem__()`; this allows iteration over the `NodeList` in `for` statements and proper support for the *len()* built-in function.

If a DOM implementation supports modification of the document, the `NodeList` implementation must also support the `__setitem__()` and `__delitem__()` methods.

DocumentType Objects

Information about the notations and entities declared by a document (including the external subset if the parser uses it and can provide the information) is available from a `DocumentType` object. The `DocumentType`

for a document is available from the `Document` object's `doctype` attribute; if there is no `DOCTYPE` declaration for the document, the document's `doctype` attribute will be set to `None` instead of an instance of this interface.

`DocumentType` is a specialization of `Node`, and adds the following attributes:

`DocumentType.publicId`
: The public identifier for the external subset of the document type definition. This will be a string or `None`.

`DocumentType.systemId`
: The system identifier for the external subset of the document type definition. This will be a URI as a string, or `None`.

`DocumentType.internalSubset`
: A string giving the complete internal subset from the document. This does not include the brackets which enclose the subset. If the document has no internal subset, this should be `None`.

`DocumentType.name`
: The name of the root element as given in the `DOCTYPE` declaration, if present.

`DocumentType.entities`
: This is a `NamedNodeMap` giving the definitions of external entities. For entity names defined more than once, only the first definition is provided (others are ignored as required by the XML recommendation). This may be `None` if the information is not provided by the parser, or if no entities are defined.

`DocumentType.notations`
: This is a `NamedNodeMap` giving the definitions of notations. For notation names defined more than once, only the first definition is provided (others are ignored as required by the XML recommendation). This may be `None` if the information is not provided by the parser, or if no notations are defined.

Document Objects

A `Document` represents an entire XML document, including its constituent elements, attributes, processing instructions, comments etc. Remember that it inherits properties from `Node`.

`Document.documentElement`
: The one and only root element of the document.

`Document.createElement(`*tagName*`)`
: Create and return a new element node. The element is not inserted into the document when it is created. You need to explicitly insert it with one of the other methods such as `insertBefore()` or `appendChild()`.

`Document.createElementNS(`*namespaceURI*`, `*tagName*`)`
: Create and return a new element with a namespace. The *tagName* may have a prefix. The element is not inserted into the document when it is created. You need to explicitly insert it with one of the other methods such as `insertBefore()` or `appendChild()`.

`Document.createTextNode(`*data*`)`
: Create and return a text node containing the data passed as a parameter. As with the other creation methods, this one does not insert the node into the tree.

`Document.createComment(`*data*`)`
: Create and return a comment node containing the data passed as a parameter. As with the other creation methods, this one does not insert the node into the tree.

`Document.createProcessingInstruction(`*target*`, `*data*`)`
: Create and return a processing instruction node containing the *target* and *data* passed as parameters. As with the other creation methods, this one does not insert the node into the tree.

`Document.createAttribute(`*name*`)`
Create and return an attribute node. This method does not associate the attribute node with any particular element. You must use `setAttributeNode()` on the appropriate `Element` object to use the newly created attribute instance.

`Document.createAttributeNS(`*namespaceURI*, *qualifiedName*`)`
Create and return an attribute node with a namespace. The *tagName* may have a prefix. This method does not associate the attribute node with any particular element. You must use `setAttributeNode()` on the appropriate `Element` object to use the newly created attribute instance.

`Document.getElementsByTagName(`*tagName*`)`
Search for all descendants (direct children, children's children, etc.) with a particular element type name.

`Document.getElementsByTagNameNS(`*namespaceURI*, *localName*`)`
Search for all descendants (direct children, children's children, etc.) with a particular namespace URI and localname. The localname is the part of the namespace after the prefix.

Element Objects

`Element` is a subclass of `Node`, so inherits all the attributes of that class.

`Element.tagName`
The element type name. In a namespace-using document it may have colons in it. The value is a string.

`Element.getElementsByTagName(`*tagName*`)`
Same as equivalent method in the `Document` class.

`Element.getElementsByTagNameNS(`*namespaceURI*, *localName*`)`
Same as equivalent method in the `Document` class.

`Element.hasAttribute(`*name*`)`
Returns true if the element has an attribute named by *name*.

`Element.hasAttributeNS(`*namespaceURI*, *localName*`)`
Returns true if the element has an attribute named by *namespaceURI* and *localName*.

`Element.getAttribute(`*name*`)`
Return the value of the attribute named by *name* as a string. If no such attribute exists, an empty string is returned, as if the attribute had no value.

`Element.getAttributeNode(`*attrname*`)`
Return the `Attr` node for the attribute named by *attrname*.

`Element.getAttributeNS(`*namespaceURI*, *localName*`)`
Return the value of the attribute named by *namespaceURI* and *localName* as a string. If no such attribute exists, an empty string is returned, as if the attribute had no value.

`Element.getAttributeNodeNS(`*namespaceURI*, *localName*`)`
Return an attribute value as a node, given a *namespaceURI* and *localName*.

`Element.removeAttribute(`*name*`)`
Remove an attribute by name. If there is no matching attribute, a *NotFoundErr* is raised.

`Element.removeAttributeNode(`*oldAttr*`)`
Remove and return *oldAttr* from the attribute list, if present. If *oldAttr* is not present, *NotFoundErr* is raised.

`Element.removeAttributeNS(`*namespaceURI*, *localName*`)`
Remove an attribute by name. Note that it uses a localName, not a qname. No exception is raised if there is no matching attribute.

Element.**setAttribute**(*name*, *value*)
Set an attribute value from a string.

Element.**setAttributeNode**(*newAttr*)
Add a new attribute node to the element, replacing an existing attribute if necessary if the `name` attribute matches. If a replacement occurs, the old attribute node will be returned. If *newAttr* is already in use, *InuseAttributeErr* will be raised.

Element.**setAttributeNodeNS**(*newAttr*)
Add a new attribute node to the element, replacing an existing attribute if necessary if the `namespaceURI` and `localName` attributes match. If a replacement occurs, the old attribute node will be returned. If *newAttr* is already in use, *InuseAttributeErr* will be raised.

Element.**setAttributeNS**(*namespaceURI*, *qname*, *value*)
Set an attribute value from a string, given a *namespaceURI* and a *qname*. Note that a qname is the whole attribute name. This is different than above.

Attr Objects

`Attr` inherits from `Node`, so inherits all its attributes.

Attr.**name**
The attribute name. In a namespace-using document it may include a colon.

Attr.**localName**
The part of the name following the colon if there is one, else the entire name. This is a read-only attribute.

Attr.**prefix**
The part of the name preceding the colon if there is one, else the empty string.

Attr.**value**
The text value of the attribute. This is a synonym for the `nodeValue` attribute.

NamedNodeMap Objects

`NamedNodeMap` does *not* inherit from `Node`.

NamedNodeMap.**length**
The length of the attribute list.

NamedNodeMap.**item**(*index*)
Return an attribute with a particular index. The order you get the attributes in is arbitrary but will be consistent for the life of a DOM. Each item is an attribute node. Get its value with the `value` attribute.

There are also experimental methods that give this class more mapping behavior. You can use them or you can use the standardized `getAttribute*()` family of methods on the `Element` objects.

Comment Objects

`Comment` represents a comment in the XML document. It is a subclass of `Node`, but cannot have child nodes.

Comment.**data**
The content of the comment as a string. The attribute contains all characters between the leading `<!--` and trailing `-->`, but does not include them.

Text and CDATASection Objects

The `Text` interface represents text in the XML document. If the parser and DOM implementation support the DOM's XML extension, portions of the text enclosed in CDATA marked sections are stored in `CDATASection` objects. These two interfaces are identical, but provide different values for the `nodeType` attribute.

These interfaces extend the `Node` interface. They cannot have child nodes.

`Text.data`
The content of the text node as a string.

Note: The use of a `CDATASection` node does not indicate that the node represents a complete CDATA marked section, only that the content of the node was part of a CDATA section. A single CDATA section may be represented by more than one node in the document tree. There is no way to determine whether two adjacent `CDATASection` nodes represent different CDATA marked sections.

ProcessingInstruction Objects

Represents a processing instruction in the XML document; this inherits from the `Node` interface and cannot have child nodes.

`ProcessingInstruction.target`
The content of the processing instruction up to the first whitespace character. This is a read-only attribute.

`ProcessingInstruction.data`
The content of the processing instruction following the first whitespace character.

Exceptions

The DOM Level 2 recommendation defines a single exception, *`DOMException`*, and a number of constants that allow applications to determine what sort of error occurred. *`DOMException`* instances carry a *`code`* attribute that provides the appropriate value for the specific exception.

The Python DOM interface provides the constants, but also expands the set of exceptions so that a specific exception exists for each of the exception codes defined by the DOM. The implementations must raise the appropriate specific exception, each of which carries the appropriate value for the *`code`* attribute.

exception `xml.dom.DOMException`
Base exception class used for all specific DOM exceptions. This exception class cannot be directly instantiated.

exception `xml.dom.DomstringSizeErr`
Raised when a specified range of text does not fit into a string. This is not known to be used in the Python DOM implementations, but may be received from DOM implementations not written in Python.

exception `xml.dom.HierarchyRequestErr`
Raised when an attempt is made to insert a node where the node type is not allowed.

exception `xml.dom.IndexSizeErr`
Raised when an index or size parameter to a method is negative or exceeds the allowed values.

exception `xml.dom.InuseAttributeErr`
Raised when an attempt is made to insert an `Attr` node that is already present elsewhere in the document.

exception xml.dom.InvalidAccessErr
Raised if a parameter or an operation is not supported on the underlying object.

exception xml.dom.InvalidCharacterErr
This exception is raised when a string parameter contains a character that is not permitted in the context it's being used in by the XML 1.0 recommendation. For example, attempting to create an `Element` node with a space in the element type name will cause this error to be raised.

exception xml.dom.InvalidModificationErr
Raised when an attempt is made to modify the type of a node.

exception xml.dom.InvalidStateErr
Raised when an attempt is made to use an object that is not defined or is no longer usable.

exception xml.dom.NamespaceErr
If an attempt is made to change any object in a way that is not permitted with regard to the Namespaces in XML recommendation, this exception is raised.

exception xml.dom.NotFoundErr
Exception when a node does not exist in the referenced context. For example, `NamedNodeMap.removeNamedItem()` will raise this if the node passed in does not exist in the map.

exception xml.dom.NotSupportedErr
Raised when the implementation does not support the requested type of object or operation.

exception xml.dom.NoDataAllowedErr
This is raised if data is specified for a node which does not support data.

exception xml.dom.NoModificationAllowedErr
Raised on attempts to modify an object where modifications are not allowed (such as for read-only nodes).

exception xml.dom.SyntaxErr
Raised when an invalid or illegal string is specified.

exception xml.dom.WrongDocumentErr
Raised when a node is inserted in a different document than it currently belongs to, and the implementation does not support migrating the node from one document to the other.

The exception codes defined in the DOM recommendation map to the exceptions described above according to this table:

Constant	Exception
DOMSTRING_SIZE_ERR	*DomstringSizeErr*
HIERARCHY_REQUEST_ERR	*HierarchyRequestErr*
INDEX_SIZE_ERR	*IndexSizeErr*
INUSE_ATTRIBUTE_ERR	*InuseAttributeErr*
INVALID_ACCESS_ERR	*InvalidAccessErr*
INVALID_CHARACTER_ERR	*InvalidCharacterErr*
INVALID_MODIFICATION_ERR	*InvalidModificationErr*
INVALID_STATE_ERR	*InvalidStateErr*
NAMESPACE_ERR	*NamespaceErr*
NOT_FOUND_ERR	*NotFoundErr*
NOT_SUPPORTED_ERR	*NotSupportedErr*
NO_DATA_ALLOWED_ERR	*NoDataAllowedErr*
NO_MODIFICATION_ALLOWED_ERR	*NoModificationAllowedErr*
SYNTAX_ERR	*SyntaxErr*
WRONG_DOCUMENT_ERR	*WrongDocumentErr*

21.6.3 Conformance

This section describes the conformance requirements and relationships between the Python DOM API, the W3C DOM recommendations, and the OMG IDL mapping for Python.

Type Mapping

The IDL types used in the DOM specification are mapped to Python types according to the following table.

IDL Type	Python Type
`boolean`	`bool` or `int`
`int`	`int`
`long int`	`int`
`unsigned int`	`int`
`DOMString`	`str` or `bytes`
`null`	`None`

Accessor Methods

The mapping from OMG IDL to Python defines accessor functions for IDL `attribute` declarations in much the way the Java mapping does. Mapping the IDL declarations

```
readonly attribute string someValue;
         attribute string anotherValue;
```

yields three accessor functions: a "get" method for `someValue` (`_get_someValue()`), and "get" and "set" methods for `anotherValue` (`_get_anotherValue()` and `_set_anotherValue()`). The mapping, in particular, does not require that the IDL attributes are accessible as normal Python attributes: `object.someValue` is *not* required to work, and may raise an *AttributeError*.

The Python DOM API, however, *does* require that normal attribute access work. This means that the typical surrogates generated by Python IDL compilers are not likely to work, and wrapper objects may be needed on the client if the DOM objects are accessed via CORBA. While this does require some additional consideration for CORBA DOM clients, the implementers with experience using DOM over CORBA from Python do not consider this a problem. Attributes that are declared `readonly` may not restrict write access in all DOM implementations.

In the Python DOM API, accessor functions are not required. If provided, they should take the form defined by the Python IDL mapping, but these methods are considered unnecessary since the attributes are accessible directly from Python. "Set" accessors should never be provided for `readonly` attributes.

The IDL definitions do not fully embody the requirements of the W3C DOM API, such as the notion of certain objects, such as the return value of `getElementsByTagName()`, being "live". The Python DOM API does not require implementations to enforce such requirements.

21.7 `xml.dom.minidom` — Minimal DOM implementation

Source code: Lib/xml/dom/minidom.py

---

xml.dom.minidom is a minimal implementation of the Document Object Model interface, with an API similar to that in other languages. It is intended to be simpler than the full DOM and also significantly smaller.

Users who are not already proficient with the DOM should consider using the *xml.etree.ElementTree* module for their XML processing instead.

Warning: The *xml.dom.minidom* module is not secure against maliciously constructed data. If you need to parse untrusted or unauthenticated data see *XML vulnerabilities*.

DOM applications typically start by parsing some XML into a DOM. With *xml.dom.minidom*, this is done through the parse functions:

```
from xml.dom.minidom import parse, parseString

dom1 = parse('c:\\temp\\mydata.xml')  # parse an XML file by name

datasource = open('c:\\temp\\mydata.xml')
dom2 = parse(datasource)  # parse an open file

dom3 = parseString('<myxml>Some data<empty/> some more data</myxml>')
```

The *parse()* function can take either a filename or an open file object.

xml.dom.minidom.parse(*filename_or_file*, *parser=None*, *bufsize=None*)
Return a `Document` from the given input. *filename_or_file* may be either a file name, or a file-like object. *parser*, if given, must be a SAX2 parser object. This function will change the document handler of the parser and activate namespace support; other parser configuration (like setting an entity resolver) must have been done in advance.

If you have XML in a string, you can use the *parseString()* function instead:

xml.dom.minidom.parseString(*string*, *parser=None*)
Return a `Document` that represents the *string*. This method creates an *io.StringIO* object for the string and passes that on to *parse()*.

Both functions return a `Document` object representing the content of the document.

What the *parse()* and *parseString()* functions do is connect an XML parser with a "DOM builder" that can accept parse events from any SAX parser and convert them into a DOM tree. The name of the functions are perhaps misleading, but are easy to grasp when learning the interfaces. The parsing of the document will be completed before these functions return; it's simply that these functions do not provide a parser implementation themselves.

You can also create a `Document` by calling a method on a "DOM Implementation" object. You can get this object either by calling the `getDOMImplementation()` function in the *xml.dom* package or the *xml.dom.minidom* module. Once you have a `Document`, you can add child nodes to it to populate the DOM:

```
from xml.dom.minidom import getDOMImplementation

impl = getDOMImplementation()

newdoc = impl.createDocument(None, "some_tag", None)
top_element = newdoc.documentElement
text = newdoc.createTextNode('Some textual content.')
top_element.appendChild(text)
```

Once you have a DOM document object, you can access the parts of your XML document through its properties and methods. These properties are defined in the DOM specification. The main property of the document object is the `documentElement` property. It gives you the main element in the XML document: the one that holds all others. Here is an example program:

```
dom3 = parseString("<myxml>Some data</myxml>")
assert dom3.documentElement.tagName == "myxml"
```

When you are finished with a DOM tree, you may optionally call the `unlink()` method to encourage early cleanup of the now-unneeded objects. `unlink()` is an *xml.dom.minidom*-specific extension to the DOM API that renders the node and its descendants are essentially useless. Otherwise, Python's garbage collector will eventually take care of the objects in the tree.

See also:

Document Object Model (DOM) Level 1 Specification The W3C recommendation for the DOM supported by *xml.dom.minidom*.

21.7.1 DOM Objects

The definition of the DOM API for Python is given as part of the *xml.dom* module documentation. This section lists the differences between the API and *xml.dom.minidom*.

`Node.unlink()`
Break internal references within the DOM so that it will be garbage collected on versions of Python without cyclic GC. Even when cyclic GC is available, using this can make large amounts of memory available sooner, so calling this on DOM objects as soon as they are no longer needed is good practice. This only needs to be called on the `Document` object, but may be called on child nodes to discard children of that node.

You can avoid calling this method explicitly by using the `with` statement. The following code will automatically unlink *dom* when the `with` block is exited:

```
with xml.dom.minidom.parse(datasource) as dom:
    ... # Work with dom.
```

`Node.writexml(`*writer*, *indent=""*, *addindent=""*, *newl=""*`)`
Write XML to the writer object. The writer should have a `write()` method which matches that of the file object interface. The *indent* parameter is the indentation of the current node. The *addindent* parameter is the incremental indentation to use for subnodes of the current one. The *newl* parameter specifies the string to use to terminate newlines.

For the `Document` node, an additional keyword argument *encoding* can be used to specify the encoding field of the XML header.

`Node.toxml(`*encoding=None*`)`
Return a string or byte string containing the XML represented by the DOM node.

With an explicit *encoding*[1] argument, the result is a byte string in the specified encoding. With no *encoding* argument, the result is a Unicode string, and the XML declaration in the resulting string does not specify an encoding. Encoding this string in an encoding other than UTF-8 is likely incorrect, since UTF-8 is the default encoding of XML.

`Node.toprettyxml(`*indent=""*, *newl=""*, *encoding=""*`)`
Return a pretty-printed version of the document. *indent* specifies the indentation string and defaults to a tabulator; *newl* specifies the string emitted at the end of each line and defaults to `\n`.

The *encoding* argument behaves like the corresponding argument of *toxml()*.

[1] The encoding name included in the XML output should conform to the appropriate standards. For example, "UTF-8" is valid, but "UTF8" is not valid in an XML document's declaration, even though Python accepts it as an encoding name. See https://www.w3.org/TR/2006/REC-xml11-20060816/#NT-EncodingDecl and https://www.iana.org/assignments/character-sets/character-sets.xhtml.

21.7.2 DOM Example

This example program is a fairly realistic example of a simple program. In this particular case, we do not take much advantage of the flexibility of the DOM.

```
import xml.dom.minidom

document = """\
<slideshow>
<title>Demo slideshow</title>
<slide><title>Slide title</title>
<point>This is a demo</point>
<point>Of a program for processing slides</point>
</slide>

<slide><title>Another demo slide</title>
<point>It is important</point>
<point>To have more than</point>
<point>one slide</point>
</slide>
</slideshow>
"""

dom = xml.dom.minidom.parseString(document)

def getText(nodelist):
    rc = []
    for node in nodelist:
        if node.nodeType == node.TEXT_NODE:
            rc.append(node.data)
    return ''.join(rc)

def handleSlideshow(slideshow):
    print("<html>")
    handleSlideshowTitle(slideshow.getElementsByTagName("title")[0])
    slides = slideshow.getElementsByTagName("slide")
    handleToc(slides)
    handleSlides(slides)
    print("</html>")

def handleSlides(slides):
    for slide in slides:
        handleSlide(slide)

def handleSlide(slide):
    handleSlideTitle(slide.getElementsByTagName("title")[0])
    handlePoints(slide.getElementsByTagName("point"))

def handleSlideshowTitle(title):
    print("<title>%s</title>" % getText(title.childNodes))

def handleSlideTitle(title):
    print("<h2>%s</h2>" % getText(title.childNodes))

def handlePoints(points):
    print("<ul>")
    for point in points:
        handlePoint(point)
```

(continues on next page)

(continued from previous page)

```
    print("</ul>")

def handlePoint(point):
    print("<li>%s</li>" % getText(point.childNodes))

def handleToc(slides):
    for slide in slides:
        title = slide.getElementsByTagName("title")[0]
        print("<p>%s</p>" % getText(title.childNodes))

handleSlideshow(dom)
```

21.7.3 minidom and the DOM standard

The *xml.dom.minidom* module is essentially a DOM 1.0-compatible DOM with some DOM 2 features (primarily namespace features).

Usage of the DOM interface in Python is straight-forward. The following mapping rules apply:

- Interfaces are accessed through instance objects. Applications should not instantiate the classes themselves; they should use the creator functions available on the `Document` object. Derived interfaces support all operations (and attributes) from the base interfaces, plus any new operations.
- Operations are used as methods. Since the DOM uses only `in` parameters, the arguments are passed in normal order (from left to right). There are no optional arguments. `void` operations return `None`.
- IDL attributes map to instance attributes. For compatibility with the OMG IDL language mapping for Python, an attribute `foo` can also be accessed through accessor methods `_get_foo()` and `_set_foo()`. `readonly` attributes must not be changed; this is not enforced at runtime.
- The types `short int`, `unsigned int`, `unsigned long long`, and `boolean` all map to Python integer objects.
- The type `DOMString` maps to Python strings. *xml.dom.minidom* supports either bytes or strings, but will normally produce strings. Values of type `DOMString` may also be `None` where allowed to have the IDL `null` value by the DOM specification from the W3C.
- `const` declarations map to variables in their respective scope (e.g. `xml.dom.minidom.Node.PROCESSING_INSTRUCTION_NODE`); they must not be changed.
- `DOMException` is currently not supported in *xml.dom.minidom*. Instead, *xml.dom.minidom* uses standard Python exceptions such as *TypeError* and *AttributeError*.
- `NodeList` objects are implemented using Python's built-in list type. These objects provide the interface defined in the DOM specification, but with earlier versions of Python they do not support the official API. They are, however, much more "Pythonic" than the interface defined in the W3C recommendations.

The following interfaces have no implementation in *xml.dom.minidom*:

- `DOMTimeStamp`
- `DocumentType`
- `DOMImplementation`
- `CharacterData`
- `CDATASection`
- `Notation`

- Entity
- EntityReference
- DocumentFragment

Most of these reflect information in the XML document that is not of general utility to most DOM users.

21.8 xml.dom.pulldom — Support for building partial DOM trees

Source code: Lib/xml/dom/pulldom.py

The *xml.dom.pulldom* module provides a "pull parser" which can also be asked to produce DOM-accessible fragments of the document where necessary. The basic concept involves pulling "events" from a stream of incoming XML and processing them. In contrast to SAX which also employs an event-driven processing model together with callbacks, the user of a pull parser is responsible for explicitly pulling events from the stream, looping over those events until either processing is finished or an error condition occurs.

> **Warning:** The *xml.dom.pulldom* module is not secure against maliciously constructed data. If you need to parse untrusted or unauthenticated data see *XML vulnerabilities*.

Example:

```
from xml.dom import pulldom

doc = pulldom.parse('sales_items.xml')
for event, node in doc:
    if event == pulldom.START_ELEMENT and node.tagName == 'item':
        if int(node.getAttribute('price')) > 50:
            doc.expandNode(node)
            print(node.toxml())
```

`event` is a constant and can be one of:

- START_ELEMENT
- END_ELEMENT
- COMMENT
- START_DOCUMENT
- END_DOCUMENT
- CHARACTERS
- PROCESSING_INSTRUCTION
- IGNORABLE_WHITESPACE

`node` is an object of type `xml.dom.minidom.Document`, `xml.dom.minidom.Element` or `xml.dom.minidom.Text`.

Since the document is treated as a "flat" stream of events, the document "tree" is implicitly traversed and the desired elements are found regardless of their depth in the tree. In other words, one does not need to consider hierarchical issues such as recursive searching of the document nodes, although if the context of elements were important, one would either need to maintain some context-related state (i.e. remembering where one is in the document at any given point) or to make use of the *DOMEventStream.expandNode()* method and switch to DOM-related processing.

class xml.dom.pulldom.**PullDom**(*documentFactory=None*)
Subclass of *xml.sax.handler.ContentHandler*.

class xml.dom.pulldom.**SAX2DOM**(*documentFactory=None*)
Subclass of *xml.sax.handler.ContentHandler*.

xml.dom.pulldom.**parse**(*stream_or_string*, *parser=None*, *bufsize=None*)
Return a *DOMEventStream* from the given input. *stream_or_string* may be either a file name, or a file-like object. *parser*, if given, must be an *XMLReader* object. This function will change the document handler of the parser and activate namespace support; other parser configuration (like setting an entity resolver) must have been done in advance.

If you have XML in a string, you can use the *parseString()* function instead:

xml.dom.pulldom.**parseString**(*string*, *parser=None*)
Return a *DOMEventStream* that represents the (Unicode) *string*.

xml.dom.pulldom.**default_bufsize**
Default value for the *bufsize* parameter to *parse()*.

The value of this variable can be changed before calling *parse()* and the new value will take effect.

21.8.1 DOMEventStream Objects

class xml.dom.pulldom.**DOMEventStream**(*stream*, *parser*, *bufsize*)

getEvent()
Return a tuple containing *event* and the current *node* as `xml.dom.minidom.Document` if event equals `START_DOCUMENT`, `xml.dom.minidom.Element` if event equals `START_ELEMENT` or `END_ELEMENT` or `xml.dom.minidom.Text` if event equals `CHARACTERS`. The current node does not contain information about its children, unless *expandNode()* is called.

expandNode(*node*)
Expands all children of *node* into *node*. Example:

```
from xml.dom import pulldom

xml = '<html><title>Foo</title> <p>Some text <div>and more</div></p> </html>'
doc = pulldom.parseString(xml)
for event, node in doc:
    if event == pulldom.START_ELEMENT and node.tagName == 'p':
        # Following statement only prints '<p/>'
        print(node.toxml())
        doc.expandNode(node)
        # Following statement prints node with all its children '<p>Some text <div>and␣
↪more</div></p>'
        print(node.toxml())
```

reset()

21.9 xml.sax — Support for SAX2 parsers

Source code: Lib/xml/sax/__init__.py

The *xml.sax* package provides a number of modules which implement the Simple API for XML (SAX) interface for Python. The package itself provides the SAX exceptions and the convenience functions which will be most used by users of the SAX API.

Warning: The *xml.sax* module is not secure against maliciously constructed data. If you need to parse untrusted or unauthenticated data see *XML vulnerabilities*.

The convenience functions are:

`xml.sax.make_parser`(*parser_list=[]*)
: Create and return a SAX *XMLReader* object. The first parser found will be used. If *parser_list* is provided, it must be a sequence of strings which name modules that have a function named `create_parser()`. Modules listed in *parser_list* will be used before modules in the default list of parsers.

`xml.sax.parse`(*filename_or_stream*, *handler*, *error_handler=handler.ErrorHandler()*)
: Create a SAX parser and use it to parse a document. The document, passed in as *filename_or_stream*, can be a filename or a file object. The *handler* parameter needs to be a SAX *ContentHandler* instance. If *error_handler* is given, it must be a SAX *ErrorHandler* instance; if omitted, *SAXParseException* will be raised on all errors. There is no return value; all work must be done by the *handler* passed in.

`xml.sax.parseString`(*string*, *handler*, *error_handler=handler.ErrorHandler()*)
: Similar to *parse()*, but parses from a buffer *string* received as a parameter. *string* must be a *str* instance or a *bytes-like object*.

  Changed in version 3.5: Added support of *str* instances.

A typical SAX application uses three kinds of objects: readers, handlers and input sources. "Reader" in this context is another term for parser, i.e. some piece of code that reads the bytes or characters from the input source, and produces a sequence of events. The events then get distributed to the handler objects, i.e. the reader invokes a method on the handler. A SAX application must therefore obtain a reader object, create or open the input sources, create the handlers, and connect these objects all together. As the final step of preparation, the reader is called to parse the input. During parsing, methods on the handler objects are called based on structural and syntactic events from the input data.

For these objects, only the interfaces are relevant; they are normally not instantiated by the application itself. Since Python does not have an explicit notion of interface, they are formally introduced as classes, but applications may use implementations which do not inherit from the provided classes. The *InputSource*, *Locator*, `Attributes`, `AttributesNS`, and *XMLReader* interfaces are defined in the module *xml.sax.xmlreader*. The handler interfaces are defined in *xml.sax.handler*. For convenience, *InputSource* (which is often instantiated directly) and the handler classes are also available from *xml.sax*. These interfaces are described below.

In addition to these classes, *xml.sax* provides the following exception classes.

exception `xml.sax.SAXException`(*msg*, *exception=None*)
: Encapsulate an XML error or warning. This class can contain basic error or warning information from either the XML parser or the application: it can be subclassed to provide additional functionality or to add localization. Note that although the handlers defined in the *ErrorHandler* interface receive instances of this exception, it is not required to actually raise the exception — it is also useful as a container for information.

  When instantiated, *msg* should be a human-readable description of the error. The optional *exception* parameter, if given, should be `None` or an exception that was caught by the parsing code and is being passed along as information.

  This is the base class for the other SAX exception classes.

exception xml.sax.SAXParseException(*msg*, *exception*, *locator*)
Subclass of *SAXException* raised on parse errors. Instances of this class are passed to the methods of the SAX *ErrorHandler* interface to provide information about the parse error. This class supports the SAX *Locator* interface as well as the *SAXException* interface.

exception xml.sax.SAXNotRecognizedException(*msg*, *exception=None*)
Subclass of *SAXException* raised when a SAX *XMLReader* is confronted with an unrecognized feature or property. SAX applications and extensions may use this class for similar purposes.

exception xml.sax.SAXNotSupportedException(*msg*, *exception=None*)
Subclass of *SAXException* raised when a SAX *XMLReader* is asked to enable a feature that is not supported, or to set a property to a value that the implementation does not support. SAX applications and extensions may use this class for similar purposes.

See also:

SAX: The Simple API for XML This site is the focal point for the definition of the SAX API. It provides a Java implementation and online documentation. Links to implementations and historical information are also available.

Module *xml.sax.handler* Definitions of the interfaces for application-provided objects.

Module *xml.sax.saxutils* Convenience functions for use in SAX applications.

Module *xml.sax.xmlreader* Definitions of the interfaces for parser-provided objects.

21.9.1 SAXException Objects

The *SAXException* exception class supports the following methods:

SAXException.getMessage()
Return a human-readable message describing the error condition.

SAXException.getException()
Return an encapsulated exception object, or `None`.

21.10 xml.sax.handler — Base classes for SAX handlers

Source code: Lib/xml/sax/handler.py

The SAX API defines four kinds of handlers: content handlers, DTD handlers, error handlers, and entity resolvers. Applications normally only need to implement those interfaces whose events they are interested in; they can implement the interfaces in a single object or in multiple objects. Handler implementations should inherit from the base classes provided in the module *xml.sax.handler*, so that all methods get default implementations.

class xml.sax.handler.ContentHandler
This is the main callback interface in SAX, and the one most important to applications. The order of events in this interface mirrors the order of the information in the document.

class xml.sax.handler.DTDHandler
Handle DTD events.

This interface specifies only those DTD events required for basic parsing (unparsed entities and attributes).

class xml.sax.handler.EntityResolver
: Basic interface for resolving entities. If you create an object implementing this interface, then register the object with your Parser, the parser will call the method in your object to resolve all external entities.

class xml.sax.handler.ErrorHandler
: Interface used by the parser to present error and warning messages to the application. The methods of this object control whether errors are immediately converted to exceptions or are handled in some other way.

In addition to these classes, *xml.sax.handler* provides symbolic constants for the feature and property names.

xml.sax.handler.feature_namespaces
: value: "http://xml.org/sax/features/namespaces"
true: Perform Namespace processing.
false: Optionally do not perform Namespace processing (implies namespace-prefixes; default).
access: (parsing) read-only; (not parsing) read/write

xml.sax.handler.feature_namespace_prefixes
: value: "http://xml.org/sax/features/namespace-prefixes"
true: Report the original prefixed names and attributes used for Namespace declarations.
false: Do not report attributes used for Namespace declarations, and optionally do not report original prefixed names (default).
access: (parsing) read-only; (not parsing) read/write

xml.sax.handler.feature_string_interning
: value: "http://xml.org/sax/features/string-interning"
true: All element names, prefixes, attribute names, Namespace URIs, and local names are interned using the built-in intern function.
false: Names are not necessarily interned, although they may be (default).
access: (parsing) read-only; (not parsing) read/write

xml.sax.handler.feature_validation
: value: "http://xml.org/sax/features/validation"
true: Report all validation errors (implies external-general-entities and external-parameter-entities).
false: Do not report validation errors.
access: (parsing) read-only; (not parsing) read/write

xml.sax.handler.feature_external_ges
: value: "http://xml.org/sax/features/external-general-entities"
true: Include all external general (text) entities.
false: Do not include external general entities.
access: (parsing) read-only; (not parsing) read/write

xml.sax.handler.feature_external_pes
: value: "http://xml.org/sax/features/external-parameter-entities"
true: Include all external parameter entities, including the external DTD subset.

false: Do not include any external parameter entities, even the external DTD subset.
access: (parsing) read-only; (not parsing) read/write

xml.sax.handler.all_features
List of all features.

xml.sax.handler.property_lexical_handler

value: "http://xml.org/sax/properties/lexical-handler"
data type: xml.sax.sax2lib.LexicalHandler (not supported in Python 2)
description: An optional extension handler for lexical events like comments.
access: read/write

xml.sax.handler.property_declaration_handler

value: "http://xml.org/sax/properties/declaration-handler"
data type: xml.sax.sax2lib.DeclHandler (not supported in Python 2)
description: An optional extension handler for DTD-related events other than notations and unparsed entities.
access: read/write

xml.sax.handler.property_dom_node

value: "http://xml.org/sax/properties/dom-node"
data type: org.w3c.dom.Node (not supported in Python 2)
description: When parsing, the current DOM node being visited if this is a DOM iterator; when not parsing, the root DOM node for iteration.
access: (parsing) read-only; (not parsing) read/write

xml.sax.handler.property_xml_string

value: "http://xml.org/sax/properties/xml-string"
data type: String
description: The literal string of characters that was the source for the current event.
access: read-only

xml.sax.handler.all_properties
List of all known property names.

21.10.1 ContentHandler Objects

Users are expected to subclass *ContentHandler* to support their application. The following methods are called by the parser on the appropriate events in the input document:

ContentHandler.setDocumentLocator(*locator*)
Called by the parser to give the application a locator for locating the origin of document events.

SAX parsers are strongly encouraged (though not absolutely required) to supply a locator: if it does so, it must supply the locator to the application by invoking this method before invoking any of the other methods in the DocumentHandler interface.

The locator allows the application to determine the end position of any document-related event, even if the parser is not reporting an error. Typically, the application will use this information for reporting its own errors (such as character content that does not match an application's business rules). The information returned by the locator is probably not sufficient for use with a search engine.

Note that the locator will return correct information only during the invocation of the events in this interface. The application should not attempt to use it at any other time.

`ContentHandler.startDocument()`
Receive notification of the beginning of a document.

The SAX parser will invoke this method only once, before any other methods in this interface or in DTDHandler (except for *setDocumentLocator()*).

`ContentHandler.endDocument()`
Receive notification of the end of a document.

The SAX parser will invoke this method only once, and it will be the last method invoked during the parse. The parser shall not invoke this method until it has either abandoned parsing (because of an unrecoverable error) or reached the end of input.

`ContentHandler.startPrefixMapping(`*prefix*, *uri*`)`
Begin the scope of a prefix-URI Namespace mapping.

The information from this event is not necessary for normal Namespace processing: the SAX XML reader will automatically replace prefixes for element and attribute names when the `feature_namespaces` feature is enabled (the default).

There are cases, however, when applications need to use prefixes in character data or in attribute values, where they cannot safely be expanded automatically; the *startPrefixMapping()* and *endPrefixMapping()* events supply the information to the application to expand prefixes in those contexts itself, if necessary.

Note that *startPrefixMapping()* and *endPrefixMapping()* events are not guaranteed to be properly nested relative to each-other: all *startPrefixMapping()* events will occur before the corresponding *startElement()* event, and all *endPrefixMapping()* events will occur after the corresponding *endElement()* event, but their order is not guaranteed.

`ContentHandler.endPrefixMapping(`*prefix*`)`
End the scope of a prefix-URI mapping.

See *startPrefixMapping()* for details. This event will always occur after the corresponding *endElement()* event, but the order of *endPrefixMapping()* events is not otherwise guaranteed.

`ContentHandler.startElement(`*name*, *attrs*`)`
Signals the start of an element in non-namespace mode.

The *name* parameter contains the raw XML 1.0 name of the element type as a string and the *attrs* parameter holds an object of the `Attributes` interface (see *The Attributes Interface*) containing the attributes of the element. The object passed as *attrs* may be re-used by the parser; holding on to a reference to it is not a reliable way to keep a copy of the attributes. To keep a copy of the attributes, use the *copy()* method of the *attrs* object.

`ContentHandler.endElement(`*name*`)`
Signals the end of an element in non-namespace mode.

The *name* parameter contains the name of the element type, just as with the *startElement()* event.

`ContentHandler.startElementNS(`*name*, *qname*, *attrs*`)`
Signals the start of an element in namespace mode.

The *name* parameter contains the name of the element type as a `(uri, localname)` tuple, the *qname* parameter contains the raw XML 1.0 name used in the source document, and the *attrs* parameter holds an instance of the `AttributesNS` interface (see *The AttributesNS Interface*) containing the attributes of the element. If no namespace is associated with the element, the *uri* component of *name* will be `None`. The object passed as *attrs* may be re-used by the parser; holding on to a reference to it is not a reliable way to keep a copy of the attributes. To keep a copy of the attributes, use the *copy()* method of the *attrs* object.

Parsers may set the *qname* parameter to `None`, unless the `feature_namespace_prefixes` feature is activated.

`ContentHandler.endElementNS(`*name*, *qname*`)`
Signals the end of an element in namespace mode.

The *name* parameter contains the name of the element type, just as with the *startElementNS()* method, likewise the *qname* parameter.

`ContentHandler.characters(`*content*`)`
Receive notification of character data.

The Parser will call this method to report each chunk of character data. SAX parsers may return all contiguous character data in a single chunk, or they may split it into several chunks; however, all of the characters in any single event must come from the same external entity so that the Locator provides useful information.

content may be a string or bytes instance; the `expat` reader module always produces strings.

Note: The earlier SAX 1 interface provided by the Python XML Special Interest Group used a more Java-like interface for this method. Since most parsers used from Python did not take advantage of the older interface, the simpler signature was chosen to replace it. To convert old code to the new interface, use *content* instead of slicing content with the old *offset* and *length* parameters.

`ContentHandler.ignorableWhitespace(`*whitespace*`)`
Receive notification of ignorable whitespace in element content.

Validating Parsers must use this method to report each chunk of ignorable whitespace (see the W3C XML 1.0 recommendation, section 2.10): non-validating parsers may also use this method if they are capable of parsing and using content models.

SAX parsers may return all contiguous whitespace in a single chunk, or they may split it into several chunks; however, all of the characters in any single event must come from the same external entity, so that the Locator provides useful information.

`ContentHandler.processingInstruction(`*target*, *data*`)`
Receive notification of a processing instruction.

The Parser will invoke this method once for each processing instruction found: note that processing instructions may occur before or after the main document element.

A SAX parser should never report an XML declaration (XML 1.0, section 2.8) or a text declaration (XML 1.0, section 4.3.1) using this method.

`ContentHandler.skippedEntity(`*name*`)`
Receive notification of a skipped entity.

The Parser will invoke this method once for each entity skipped. Non-validating processors may skip entities if they have not seen the declarations (because, for example, the entity was declared in an external DTD subset). All processors may skip external entities, depending on the values of the `feature_external_ges` and the `feature_external_pes` properties.

21.10.2 DTDHandler Objects

DTDHandler instances provide the following methods:

`DTDHandler.notationDecl(`*name*, *publicId*, *systemId*`)`
Handle a notation declaration event.

`DTDHandler.unparsedEntityDecl(`*name*, *publicId*, *systemId*, *ndata*`)`
Handle an unparsed entity declaration event.

21.10.3 EntityResolver Objects

EntityResolver.**resolveEntity**(*publicId*, *systemId*)
Resolve the system identifier of an entity and return either the system identifier to read from as a string, or an InputSource to read from. The default implementation returns *systemId*.

21.10.4 ErrorHandler Objects

Objects with this interface are used to receive error and warning information from the *XMLReader*. If you create an object that implements this interface, then register the object with your *XMLReader*, the parser will call the methods in your object to report all warnings and errors. There are three levels of errors available: warnings, (possibly) recoverable errors, and unrecoverable errors. All methods take a SAXParseException as the only parameter. Errors and warnings may be converted to an exception by raising the passed-in exception object.

ErrorHandler.**error**(*exception*)
Called when the parser encounters a recoverable error. If this method does not raise an exception, parsing may continue, but further document information should not be expected by the application. Allowing the parser to continue may allow additional errors to be discovered in the input document.

ErrorHandler.**fatalError**(*exception*)
Called when the parser encounters an error it cannot recover from; parsing is expected to terminate when this method returns.

ErrorHandler.**warning**(*exception*)
Called when the parser presents minor warning information to the application. Parsing is expected to continue when this method returns, and document information will continue to be passed to the application. Raising an exception in this method will cause parsing to end.

21.11 xml.sax.saxutils — SAX Utilities

Source code: Lib/xml/sax/saxutils.py

The module *xml.sax.saxutils* contains a number of classes and functions that are commonly useful when creating SAX applications, either in direct use, or as base classes.

xml.sax.saxutils.**escape**(*data*, *entities={}*)
Escape '&', '<', and '>' in a string of data.

You can escape other strings of data by passing a dictionary as the optional *entities* parameter. The keys and values must all be strings; each key will be replaced with its corresponding value. The characters '&', '<' and '>' are always escaped, even if *entities* is provided.

xml.sax.saxutils.**unescape**(*data*, *entities={}*)
Unescape '&', '<', and '>' in a string of data.

You can unescape other strings of data by passing a dictionary as the optional *entities* parameter. The keys and values must all be strings; each key will be replaced with its corresponding value. '&', '<', and '>' are always unescaped, even if *entities* is provided.

xml.sax.saxutils.**quoteattr**(*data*, *entities={}*)
Similar to *escape()*, but also prepares *data* to be used as an attribute value. The return value is a quoted version of *data* with any additional required replacements. *quoteattr()* will select a quote character based on the content of *data*, attempting to avoid encoding any quote characters in the string. If both single- and double-quote characters are already in *data*, the double-quote characters

will be encoded and *data* will be wrapped in double-quotes. The resulting string can be used directly as an attribute value:

```
>>> print("<element attr=%s>" % quoteattr("ab ' cd \" ef"))
<element attr="ab ' cd &quot; ef">
```

This function is useful when generating attribute values for HTML or any SGML using the reference concrete syntax.

class xml.sax.saxutils.XMLGenerator(*out=None*, *encoding='iso-8859-1'*, *short_empty_elements=False*)

This class implements the *ContentHandler* interface by writing SAX events back into an XML document. In other words, using an *XMLGenerator* as the content handler will reproduce the original document being parsed. *out* should be a file-like object which will default to *sys.stdout*. *encoding* is the encoding of the output stream which defaults to `'iso-8859-1'`. *short_empty_elements* controls the formatting of elements that contain no content: if `False` (the default) they are emitted as a pair of start/end tags, if set to `True` they are emitted as a single self-closed tag.

New in version 3.2: The *short_empty_elements* parameter.

class xml.sax.saxutils.XMLFilterBase(*base*)

This class is designed to sit between an *XMLReader* and the client application's event handlers. By default, it does nothing but pass requests up to the reader and events on to the handlers unmodified, but subclasses can override specific methods to modify the event stream or the configuration requests as they pass through.

xml.sax.saxutils.prepare_input_source(*source*, *base=''*)

This function takes an input source and an optional base URL and returns a fully resolved *InputSource* object ready for reading. The input source can be given as a string, a file-like object, or an *InputSource* object; parsers will use this function to implement the polymorphic *source* argument to their `parse()` method.

21.12 xml.sax.xmlreader — Interface for XML parsers

Source code: Lib/xml/sax/xmlreader.py

SAX parsers implement the *XMLReader* interface. They are implemented in a Python module, which must provide a function `create_parser()`. This function is invoked by *xml.sax.make_parser()* with no arguments to create a new parser object.

class xml.sax.xmlreader.XMLReader

Base class which can be inherited by SAX parsers.

class xml.sax.xmlreader.IncrementalParser

In some cases, it is desirable not to parse an input source at once, but to feed chunks of the document as they get available. Note that the reader will normally not read the entire file, but read it in chunks as well; still `parse()` won't return until the entire document is processed. So these interfaces should be used if the blocking behaviour of `parse()` is not desirable.

When the parser is instantiated it is ready to begin accepting data from the feed method immediately. After parsing has been finished with a call to close the reset method must be called to make the parser ready to accept new data, either from feed or using the parse method.

Note that these methods must *not* be called during parsing, that is, after parse has been called and before it returns.

By default, the class also implements the parse method of the XMLReader interface using the feed, close and reset methods of the IncrementalParser interface as a convenience to SAX 2.0 driver writers.

class xml.sax.xmlreader.Locator
Interface for associating a SAX event with a document location. A locator object will return valid results only during calls to DocumentHandler methods; at any other time, the results are unpredictable. If information is not available, methods may return `None`.

class xml.sax.xmlreader.InputSource(*system_id=None*)
Encapsulation of the information needed by the *XMLReader* to read entities.

This class may include information about the public identifier, system identifier, byte stream (possibly with character encoding information) and/or the character stream of an entity.

Applications will create objects of this class for use in the *XMLReader.parse()* method and for returning from EntityResolver.resolveEntity.

An *InputSource* belongs to the application, the *XMLReader* is not allowed to modify *InputSource* objects passed to it from the application, although it may make copies and modify those.

class xml.sax.xmlreader.AttributesImpl(*attrs*)
This is an implementation of the `Attributes` interface (see section *The Attributes Interface*). This is a dictionary-like object which represents the element attributes in a `startElement()` call. In addition to the most useful dictionary operations, it supports a number of other methods as described by the interface. Objects of this class should be instantiated by readers; *attrs* must be a dictionary-like object containing a mapping from attribute names to attribute values.

class xml.sax.xmlreader.AttributesNSImpl(*attrs*, *qnames*)
Namespace-aware variant of *AttributesImpl*, which will be passed to `startElementNS()`. It is derived from *AttributesImpl*, but understands attribute names as two-tuples of *namespaceURI* and *localname*. In addition, it provides a number of methods expecting qualified names as they appear in the original document. This class implements the `AttributesNS` interface (see section *The AttributesNS Interface*).

21.12.1 XMLReader Objects

The *XMLReader* interface supports the following methods:

XMLReader.parse(*source*)
Process an input source, producing SAX events. The *source* object can be a system identifier (a string identifying the input source – typically a file name or a URL), a file-like object, or an *InputSource* object. When *parse()* returns, the input is completely processed, and the parser object can be discarded or reset.

Changed in version 3.5: Added support of character streams.

XMLReader.getContentHandler()
Return the current *ContentHandler*.

XMLReader.setContentHandler(*handler*)
Set the current *ContentHandler*. If no *ContentHandler* is set, content events will be discarded.

XMLReader.getDTDHandler()
Return the current *DTDHandler*.

XMLReader.setDTDHandler(*handler*)
Set the current *DTDHandler*. If no *DTDHandler* is set, DTD events will be discarded.

XMLReader.getEntityResolver()
Return the current *EntityResolver*.

XMLReader.setEntityResolver(*handler*)
Set the current *EntityResolver*. If no *EntityResolver* is set, attempts to resolve an external entity will result in opening the system identifier for the entity, and fail if it is not available.

XMLReader.getErrorHandler()
Return the current *ErrorHandler*.

XMLReader.setErrorHandler(*handler*)
Set the current error handler. If no *ErrorHandler* is set, errors will be raised as exceptions, and warnings will be printed.

XMLReader.setLocale(*locale*)
Allow an application to set the locale for errors and warnings.

SAX parsers are not required to provide localization for errors and warnings; if they cannot support the requested locale, however, they must raise a SAX exception. Applications may request a locale change in the middle of a parse.

XMLReader.getFeature(*featurename*)
Return the current setting for feature *featurename*. If the feature is not recognized, SAXNotRecognizedException is raised. The well-known featurenames are listed in the module *xml.sax.handler*.

XMLReader.setFeature(*featurename*, *value*)
Set the *featurename* to *value*. If the feature is not recognized, SAXNotRecognizedException is raised. If the feature or its setting is not supported by the parser, *SAXNotSupportedException* is raised.

XMLReader.getProperty(*propertyname*)
Return the current setting for property *propertyname*. If the property is not recognized, a SAXNotRecognizedException is raised. The well-known propertynames are listed in the module *xml.sax.handler*.

XMLReader.setProperty(*propertyname*, *value*)
Set the *propertyname* to *value*. If the property is not recognized, SAXNotRecognizedException is raised. If the property or its setting is not supported by the parser, *SAXNotSupportedException* is raised.

21.12.2 IncrementalParser Objects

Instances of *IncrementalParser* offer the following additional methods:

IncrementalParser.feed(*data*)
Process a chunk of *data*.

IncrementalParser.close()
Assume the end of the document. That will check well-formedness conditions that can be checked only at the end, invoke handlers, and may clean up resources allocated during parsing.

IncrementalParser.reset()
This method is called after close has been called to reset the parser so that it is ready to parse new documents. The results of calling parse or feed after close without calling reset are undefined.

21.12.3 Locator Objects

Instances of *Locator* provide these methods:

Locator.getColumnNumber()
Return the column number where the current event begins.

Locator.getLineNumber()
Return the line number where the current event begins.

Locator.getPublicId()
Return the public identifier for the current event.

Locator.getSystemId()
Return the system identifier for the current event.

21.12.4 InputSource Objects

InputSource.setPublicId(*id*)
Sets the public identifier of this *InputSource*.

InputSource.getPublicId()
Returns the public identifier of this *InputSource*.

InputSource.setSystemId(*id*)
Sets the system identifier of this *InputSource*.

InputSource.getSystemId()
Returns the system identifier of this *InputSource*.

InputSource.setEncoding(*encoding*)
Sets the character encoding of this *InputSource*.

The encoding must be a string acceptable for an XML encoding declaration (see section 4.3.3 of the XML recommendation).

The encoding attribute of the *InputSource* is ignored if the *InputSource* also contains a character stream.

InputSource.getEncoding()
Get the character encoding of this InputSource.

InputSource.setByteStream(*bytefile*)
Set the byte stream (a *binary file*) for this input source.

The SAX parser will ignore this if there is also a character stream specified, but it will use a byte stream in preference to opening a URI connection itself.

If the application knows the character encoding of the byte stream, it should set it with the setEncoding method.

InputSource.getByteStream()
Get the byte stream for this input source.

The getEncoding method will return the character encoding for this byte stream, or `None` if unknown.

InputSource.setCharacterStream(*charfile*)
Set the character stream (a *text file*) for this input source.

If there is a character stream specified, the SAX parser will ignore any byte stream and will not attempt to open a URI connection to the system identifier.

InputSource.getCharacterStream()
Get the character stream for this input source.

21.12.5 The `Attributes` Interface

`Attributes` objects implement a portion of the *mapping protocol*, including the methods `copy()`, `get()`, `__contains__()`, `items()`, `keys()`, and `values()`. The following methods are also provided:

Attributes.getLength()
Return the number of attributes.

Attributes.getNames()
Return the names of the attributes.

`Attributes.getType(`*name*`)`
Returns the type of the attribute *name*, which is normally `'CDATA'`.

`Attributes.getValue(`*name*`)`
Return the value of attribute *name*.

21.12.6 The `AttributesNS` Interface

This interface is a subtype of the `Attributes` interface (see section *The Attributes Interface*). All methods supported by that interface are also available on `AttributesNS` objects.

The following methods are also available:

`AttributesNS.getValueByQName(`*name*`)`
Return the value for a qualified name.

`AttributesNS.getNameByQName(`*name*`)`
Return the `(namespace, localname)` pair for a qualified *name*.

`AttributesNS.getQNameByName(`*name*`)`
Return the qualified name for a `(namespace, localname)` pair.

`AttributesNS.getQNames()`
Return the qualified names of all attributes.

21.13 `xml.parsers.expat` — Fast XML parsing using Expat

Warning: The `pyexpat` module is not secure against maliciously constructed data. If you need to parse untrusted or unauthenticated data see *XML vulnerabilities*.

The *`xml.parsers.expat`* module is a Python interface to the Expat non-validating XML parser. The module provides a single extension type, `xmlparser`, that represents the current state of an XML parser. After an `xmlparser` object has been created, various attributes of the object can be set to handler functions. When an XML document is then fed to the parser, the handler functions are called for the character data and markup in the XML document.

This module uses the `pyexpat` module to provide access to the Expat parser. Direct use of the `pyexpat` module is deprecated.

This module provides one exception and one type object:

`exception xml.parsers.expat.ExpatError`
The exception raised when Expat reports an error. See section *ExpatError Exceptions* for more information on interpreting Expat errors.

`exception xml.parsers.expat.error`
Alias for *`ExpatError`*.

`xml.parsers.expat.XMLParserType`
The type of the return values from the *`ParserCreate()`* function.

The *`xml.parsers.expat`* module contains two functions:

`xml.parsers.expat.ErrorString(`*errno*`)`
Returns an explanatory string for a given error number *errno*.

xml.parsers.expat.ParserCreate(*encoding=None*, *namespace_separator=None*)

Creates and returns a new xmlparser object. *encoding*, if specified, must be a string naming the encoding used by the XML data. Expat doesn't support as many encodings as Python does, and its repertoire of encodings can't be extended; it supports UTF-8, UTF-16, ISO-8859-1 (Latin1), and ASCII. If *encoding*[1] is given it will override the implicit or explicit encoding of the document.

Expat can optionally do XML namespace processing for you, enabled by providing a value for *namespace_separator*. The value must be a one-character string; a *ValueError* will be raised if the string has an illegal length (None is considered the same as omission). When namespace processing is enabled, element type names and attribute names that belong to a namespace will be expanded. The element name passed to the element handlers StartElementHandler and EndElementHandler will be the concatenation of the namespace URI, the namespace separator character, and the local part of the name. If the namespace separator is a zero byte (chr(0)) then the namespace URI and the local part will be concatenated without any separator.

For example, if *namespace_separator* is set to a space character (' ') and the following document is parsed:

```
<?xml version="1.0"?>
<root xmlns    = "http://default-namespace.org/"
      xmlns:py = "http://www.python.org/ns/">
  <py:elem1 />
  <elem2 xmlns="" />
</root>
```

StartElementHandler will receive the following strings for each element:

```
http://default-namespace.org/ root
http://www.python.org/ns/ elem1
elem2
```

Due to limitations in the Expat library used by pyexpat, the xmlparser instance returned can only be used to parse a single XML document. Call ParserCreate for each document to provide unique parser instances.

See also:

The Expat XML Parser Home page of the Expat project.

21.13.1 XMLParser Objects

xmlparser objects have the following methods:

xmlparser.Parse(*data*[, *isfinal*])

Parses the contents of the string *data*, calling the appropriate handler functions to process the parsed data. *isfinal* must be true on the final call to this method; it allows the parsing of a single file in fragments, not the submission of multiple files. *data* can be the empty string at any time.

xmlparser.ParseFile(*file*)

Parse XML data reading from the object *file*. *file* only needs to provide the read(nbytes) method, returning the empty string when there's no more data.

xmlparser.SetBase(*base*)

Sets the base to be used for resolving relative URIs in system identifiers in declarations. Resolving relative identifiers is left to the application: this value will be passed through as the *base* argument

[1] The encoding string included in XML output should conform to the appropriate standards. For example, "UTF-8" is valid, but "UTF8" is not. See https://www.w3.org/TR/2006/REC-xml11-20060816/#NT-EncodingDecl and https://www.iana.org/assignments/character-sets/character-sets.xhtml.

to the *ExternalEntityRefHandler()*, *NotationDeclHandler()*, and *UnparsedEntityDeclHandler()* functions.

xmlparser.GetBase()
Returns a string containing the base set by a previous call to *SetBase()*, or `None` if *SetBase()* hasn't been called.

xmlparser.GetInputContext()
Returns the input data that generated the current event as a string. The data is in the encoding of the entity which contains the text. When called while an event handler is not active, the return value is `None`.

xmlparser.ExternalEntityParserCreate(*context*[, *encoding*])
Create a "child" parser which can be used to parse an external parsed entity referred to by content parsed by the parent parser. The *context* parameter should be the string passed to the *ExternalEntityRefHandler()* handler function, described below. The child parser is created with the *ordered_attributes* and *specified_attributes* set to the values of this parser.

xmlparser.SetParamEntityParsing(*flag*)
Control parsing of parameter entities (including the external DTD subset). Possible *flag* values are `XML_PARAM_ENTITY_PARSING_NEVER`, `XML_PARAM_ENTITY_PARSING_UNLESS_STANDALONE` and `XML_PARAM_ENTITY_PARSING_ALWAYS`. Return true if setting the flag was successful.

xmlparser.UseForeignDTD([*flag*])
Calling this with a true value for *flag* (the default) will cause Expat to call the *ExternalEntityRefHandler* with *None* for all arguments to allow an alternate DTD to be loaded. If the document does not contain a document type declaration, the *ExternalEntityRefHandler* will still be called, but the *StartDoctypeDeclHandler* and *EndDoctypeDeclHandler* will not be called.

Passing a false value for *flag* will cancel a previous call that passed a true value, but otherwise has no effect.

This method can only be called before the *Parse()* or *ParseFile()* methods are called; calling it after either of those have been called causes *ExpatError* to be raised with the *code* attribute set to `errors.codes[errors.XML_ERROR_CANT_CHANGE_FEATURE_ONCE_PARSING]`.

`xmlparser` objects have the following attributes:

xmlparser.buffer_size
The size of the buffer used when *buffer_text* is true. A new buffer size can be set by assigning a new integer value to this attribute. When the size is changed, the buffer will be flushed.

xmlparser.buffer_text
Setting this to true causes the `xmlparser` object to buffer textual content returned by Expat to avoid multiple calls to the *CharacterDataHandler()* callback whenever possible. This can improve performance substantially since Expat normally breaks character data into chunks at every line ending. This attribute is false by default, and may be changed at any time.

xmlparser.buffer_used
If *buffer_text* is enabled, the number of bytes stored in the buffer. These bytes represent UTF-8 encoded text. This attribute has no meaningful interpretation when *buffer_text* is false.

xmlparser.ordered_attributes
Setting this attribute to a non-zero integer causes the attributes to be reported as a list rather than a dictionary. The attributes are presented in the order found in the document text. For each attribute, two list entries are presented: the attribute name and the attribute value. (Older versions of this module also used this format.) By default, this attribute is false; it may be changed at any time.

xmlparser.specified_attributes
If set to a non-zero integer, the parser will report only those attributes which were specified in the document instance and not those which were derived from attribute declarations. Applications which

set this need to be especially careful to use what additional information is available from the declarations as needed to comply with the standards for the behavior of XML processors. By default, this attribute is false; it may be changed at any time.

The following attributes contain values relating to the most recent error encountered by an `xmlparser` object, and will only have correct values once a call to `Parse()` or `ParseFile()` has raised an *xml.parsers.expat.ExpatError* exception.

`xmlparser.ErrorByteIndex`
Byte index at which an error occurred.

`xmlparser.ErrorCode`
Numeric code specifying the problem. This value can be passed to the *ErrorString()* function, or compared to one of the constants defined in the `errors` object.

`xmlparser.ErrorColumnNumber`
Column number at which an error occurred.

`xmlparser.ErrorLineNumber`
Line number at which an error occurred.

The following attributes contain values relating to the current parse location in an `xmlparser` object. During a callback reporting a parse event they indicate the location of the first of the sequence of characters that generated the event. When called outside of a callback, the position indicated will be just past the last parse event (regardless of whether there was an associated callback).

`xmlparser.CurrentByteIndex`
Current byte index in the parser input.

`xmlparser.CurrentColumnNumber`
Current column number in the parser input.

`xmlparser.CurrentLineNumber`
Current line number in the parser input.

Here is the list of handlers that can be set. To set a handler on an `xmlparser` object *o*, use `o.handlername = func`. *handlername* must be taken from the following list, and *func* must be a callable object accepting the correct number of arguments. The arguments are all strings, unless otherwise stated.

`xmlparser.XmlDeclHandler(`*version*, *encoding*, *standalone*`)`
Called when the XML declaration is parsed. The XML declaration is the (optional) declaration of the applicable version of the XML recommendation, the encoding of the document text, and an optional "standalone" declaration. *version* and *encoding* will be strings, and *standalone* will be `1` if the document is declared standalone, `0` if it is declared not to be standalone, or `-1` if the standalone clause was omitted. This is only available with Expat version 1.95.0 or newer.

`xmlparser.StartDoctypeDeclHandler(`*doctypeName*, *systemId*, *publicId*, *has_internal_subset*`)`
Called when Expat begins parsing the document type declaration (`<!DOCTYPE ...`). The *doctypeName* is provided exactly as presented. The *systemId* and *publicId* parameters give the system and public identifiers if specified, or `None` if omitted. *has_internal_subset* will be true if the document contains and internal document declaration subset. This requires Expat version 1.2 or newer.

`xmlparser.EndDoctypeDeclHandler()`
Called when Expat is done parsing the document type declaration. This requires Expat version 1.2 or newer.

`xmlparser.ElementDeclHandler(`*name*, *model*`)`
Called once for each element type declaration. *name* is the name of the element type, and *model* is a representation of the content model.

`xmlparser.AttlistDeclHandler(`*elname*, *attname*, *type*, *default*, *required*`)`
Called for each declared attribute for an element type. If an attribute list declaration declares three attributes, this handler is called three times, once for each attribute. *elname* is the name of the element

to which the declaration applies and *attname* is the name of the attribute declared. The attribute type is a string passed as *type*; the possible values are `'CDATA'`, `'ID'`, `'IDREF'`, ... *default* gives the default value for the attribute used when the attribute is not specified by the document instance, or `None` if there is no default value (`#IMPLIED` values). If the attribute is required to be given in the document instance, *required* will be true. This requires Expat version 1.95.0 or newer.

xmlparser.StartElementHandler(*name*, *attributes*)
Called for the start of every element. *name* is a string containing the element name, and *attributes* is the element attributes. If *ordered_attributes* is true, this is a list (see *ordered_attributes* for a full description). Otherwise it's a dictionary mapping names to values.

xmlparser.EndElementHandler(*name*)
Called for the end of every element.

xmlparser.ProcessingInstructionHandler(*target*, *data*)
Called for every processing instruction.

xmlparser.CharacterDataHandler(*data*)
Called for character data. This will be called for normal character data, CDATA marked content, and ignorable whitespace. Applications which must distinguish these cases can use the *StartCdataSectionHandler*, *EndCdataSectionHandler*, and *ElementDeclHandler* callbacks to collect the required information.

xmlparser.UnparsedEntityDeclHandler(*entityName*, *base*, *systemId*, *publicId*, *notationName*)
Called for unparsed (NDATA) entity declarations. This is only present for version 1.2 of the Expat library; for more recent versions, use *EntityDeclHandler* instead. (The underlying function in the Expat library has been declared obsolete.)

xmlparser.EntityDeclHandler(*entityName*, *is_parameter_entity*, *value*, *base*, *systemId*, *publicId*, *notationName*)
Called for all entity declarations. For parameter and internal entities, *value* will be a string giving the declared contents of the entity; this will be `None` for external entities. The *notationName* parameter will be `None` for parsed entities, and the name of the notation for unparsed entities. *is_parameter_entity* will be true if the entity is a parameter entity or false for general entities (most applications only need to be concerned with general entities). This is only available starting with version 1.95.0 of the Expat library.

xmlparser.NotationDeclHandler(*notationName*, *base*, *systemId*, *publicId*)
Called for notation declarations. *notationName*, *base*, and *systemId*, and *publicId* are strings if given. If the public identifier is omitted, *publicId* will be `None`.

xmlparser.StartNamespaceDeclHandler(*prefix*, *uri*)
Called when an element contains a namespace declaration. Namespace declarations are processed before the *StartElementHandler* is called for the element on which declarations are placed.

xmlparser.EndNamespaceDeclHandler(*prefix*)
Called when the closing tag is reached for an element that contained a namespace declaration. This is called once for each namespace declaration on the element in the reverse of the order for which the *StartNamespaceDeclHandler* was called to indicate the start of each namespace declaration's scope. Calls to this handler are made after the corresponding *EndElementHandler* for the end of the element.

xmlparser.CommentHandler(*data*)
Called for comments. *data* is the text of the comment, excluding the leading `'<!--'` and trailing `'-->'`.

xmlparser.StartCdataSectionHandler()
Called at the start of a CDATA section. This and *EndCdataSectionHandler* are needed to be able to identify the syntactical start and end for CDATA sections.

xmlparser.EndCdataSectionHandler()
Called at the end of a CDATA section.

xmlparser.DefaultHandler(*data*)
: Called for any characters in the XML document for which no applicable handler has been specified. This means characters that are part of a construct which could be reported, but for which no handler has been supplied.

xmlparser.DefaultHandlerExpand(*data*)
: This is the same as the *DefaultHandler()*, but doesn't inhibit expansion of internal entities. The entity reference will not be passed to the default handler.

xmlparser.NotStandaloneHandler()
: Called if the XML document hasn't been declared as being a standalone document. This happens when there is an external subset or a reference to a parameter entity, but the XML declaration does not set standalone to `yes` in an XML declaration. If this handler returns `0`, then the parser will raise an `XML_ERROR_NOT_STANDALONE` error. If this handler is not set, no exception is raised by the parser for this condition.

xmlparser.ExternalEntityRefHandler(*context*, *base*, *systemId*, *publicId*)
: Called for references to external entities. *base* is the current base, as set by a previous call to *SetBase()*. The public and system identifiers, *systemId* and *publicId*, are strings if given; if the public identifier is not given, *publicId* will be `None`. The *context* value is opaque and should only be used as described below.

  For external entities to be parsed, this handler must be implemented. It is responsible for creating the sub-parser using `ExternalEntityParserCreate(context)`, initializing it with the appropriate callbacks, and parsing the entity. This handler should return an integer; if it returns `0`, the parser will raise an `XML_ERROR_EXTERNAL_ENTITY_HANDLING` error, otherwise parsing will continue.

  If this handler is not provided, external entities are reported by the *DefaultHandler* callback, if provided.

21.13.2 ExpatError Exceptions

ExpatError exceptions have a number of interesting attributes:

ExpatError.code
: Expat's internal error number for the specific error. The *errors.messages* dictionary maps these error numbers to Expat's error messages. For example:

```
from xml.parsers.expat import ParserCreate, ExpatError, errors

p = ParserCreate()
try:
    p.Parse(some_xml_document)
except ExpatError as err:
    print("Error:", errors.messages[err.code])
```

  The *errors* module also provides error message constants and a dictionary *codes* mapping these messages back to the error codes, see below.

ExpatError.lineno
: Line number on which the error was detected. The first line is numbered `1`.

ExpatError.offset
: Character offset into the line where the error occurred. The first column is numbered `0`.

21.13.3 Example

The following program defines three handlers that just print out their arguments.

```
import xml.parsers.expat

# 3 handler functions
def start_element(name, attrs):
    print('Start element:', name, attrs)
def end_element(name):
    print('End element:', name)
def char_data(data):
    print('Character data:', repr(data))

p = xml.parsers.expat.ParserCreate()

p.StartElementHandler = start_element
p.EndElementHandler = end_element
p.CharacterDataHandler = char_data

p.Parse("""<?xml version="1.0"?>
<parent id="top"><child1 name="paul">Text goes here</child1>
<child2 name="fred">More text</child2>
</parent>""", 1)
```

The output from this program is:

```
Start element: parent {'id': 'top'}
Start element: child1 {'name': 'paul'}
Character data: 'Text goes here'
End element: child1
Character data: '\n'
Start element: child2 {'name': 'fred'}
Character data: 'More text'
End element: child2
Character data: '\n'
End element: parent
```

21.13.4 Content Model Descriptions

Content models are described using nested tuples. Each tuple contains four values: the type, the quantifier, the name, and a tuple of children. Children are simply additional content model descriptions.

The values of the first two fields are constants defined in the *xml.parsers.expat.model* module. These constants can be collected in two groups: the model type group and the quantifier group.

The constants in the model type group are:

xml.parsers.expat.model.XML_CTYPE_ANY
The element named by the model name was declared to have a content model of `ANY`.

xml.parsers.expat.model.XML_CTYPE_CHOICE
The named element allows a choice from a number of options; this is used for content models such as `(A | B | C)`.

xml.parsers.expat.model.XML_CTYPE_EMPTY
Elements which are declared to be `EMPTY` have this model type.

xml.parsers.expat.model.XML_CTYPE_MIXED

xml.parsers.expat.model.XML_CTYPE_NAME

xml.parsers.expat.model.**XML_CTYPE_SEQ**
: Models which represent a series of models which follow one after the other are indicated with this model type. This is used for models such as `(A, B, C)`.

The constants in the quantifier group are:

xml.parsers.expat.model.**XML_CQUANT_NONE**
: No modifier is given, so it can appear exactly once, as for `A`.

xml.parsers.expat.model.**XML_CQUANT_OPT**
: The model is optional: it can appear once or not at all, as for `A?`.

xml.parsers.expat.model.**XML_CQUANT_PLUS**
: The model must occur one or more times (like `A+`).

xml.parsers.expat.model.**XML_CQUANT_REP**
: The model must occur zero or more times, as for `A*`.

21.13.5 Expat error constants

The following constants are provided in the *xml.parsers.expat.errors* module. These constants are useful in interpreting some of the attributes of the `ExpatError` exception objects raised when an error has occurred. Since for backwards compatibility reasons, the constants' value is the error *message* and not the numeric error *code*, you do this by comparing its *code* attribute with `errors.codes[errors.XML_ERROR_`*CONSTANT_NAME*`]`.

The `errors` module has the following attributes:

xml.parsers.expat.errors.**codes**
: A dictionary mapping numeric error codes to their string descriptions.

  New in version 3.2.

xml.parsers.expat.errors.**messages**
: A dictionary mapping string descriptions to their error codes.

  New in version 3.2.

xml.parsers.expat.errors.**XML_ERROR_ASYNC_ENTITY**

xml.parsers.expat.errors.**XML_ERROR_ATTRIBUTE_EXTERNAL_ENTITY_REF**
: An entity reference in an attribute value referred to an external entity instead of an internal entity.

xml.parsers.expat.errors.**XML_ERROR_BAD_CHAR_REF**
: A character reference referred to a character which is illegal in XML (for example, character `0`, or '`&#0;`').

xml.parsers.expat.errors.**XML_ERROR_BINARY_ENTITY_REF**
: An entity reference referred to an entity which was declared with a notation, so cannot be parsed.

xml.parsers.expat.errors.**XML_ERROR_DUPLICATE_ATTRIBUTE**
: An attribute was used more than once in a start tag.

xml.parsers.expat.errors.**XML_ERROR_INCORRECT_ENCODING**

xml.parsers.expat.errors.**XML_ERROR_INVALID_TOKEN**
: Raised when an input byte could not properly be assigned to a character; for example, a NUL byte (value `0`) in a UTF-8 input stream.

xml.parsers.expat.errors.**XML_ERROR_JUNK_AFTER_DOC_ELEMENT**
: Something other than whitespace occurred after the document element.

xml.parsers.expat.errors.**XML_ERROR_MISPLACED_XML_PI**
: An XML declaration was found somewhere other than the start of the input data.

xml.parsers.expat.errors.XML_ERROR_NO_ELEMENTS
: The document contains no elements (XML requires all documents to contain exactly one top-level element)..

xml.parsers.expat.errors.XML_ERROR_NO_MEMORY
: Expat was not able to allocate memory internally.

xml.parsers.expat.errors.XML_ERROR_PARAM_ENTITY_REF
: A parameter entity reference was found where it was not allowed.

xml.parsers.expat.errors.XML_ERROR_PARTIAL_CHAR
: An incomplete character was found in the input.

xml.parsers.expat.errors.XML_ERROR_RECURSIVE_ENTITY_REF
: An entity reference contained another reference to the same entity; possibly via a different name, and possibly indirectly.

xml.parsers.expat.errors.XML_ERROR_SYNTAX
: Some unspecified syntax error was encountered.

xml.parsers.expat.errors.XML_ERROR_TAG_MISMATCH
: An end tag did not match the innermost open start tag.

xml.parsers.expat.errors.XML_ERROR_UNCLOSED_TOKEN
: Some token (such as a start tag) was not closed before the end of the stream or the next token was encountered.

xml.parsers.expat.errors.XML_ERROR_UNDEFINED_ENTITY
: A reference was made to an entity which was not defined.

xml.parsers.expat.errors.XML_ERROR_UNKNOWN_ENCODING
: The document encoding is not supported by Expat.

xml.parsers.expat.errors.XML_ERROR_UNCLOSED_CDATA_SECTION
: A CDATA marked section was not closed.

xml.parsers.expat.errors.XML_ERROR_EXTERNAL_ENTITY_HANDLING

xml.parsers.expat.errors.XML_ERROR_NOT_STANDALONE
: The parser determined that the document was not "standalone" though it declared itself to be in the XML declaration, and the `NotStandaloneHandler` was set and returned `0`.

xml.parsers.expat.errors.XML_ERROR_UNEXPECTED_STATE

xml.parsers.expat.errors.XML_ERROR_ENTITY_DECLARED_IN_PE

xml.parsers.expat.errors.XML_ERROR_FEATURE_REQUIRES_XML_DTD
: An operation was requested that requires DTD support to be compiled in, but Expat was configured without DTD support. This should never be reported by a standard build of the *xml.parsers.expat* module.

xml.parsers.expat.errors.XML_ERROR_CANT_CHANGE_FEATURE_ONCE_PARSING
: A behavioral change was requested after parsing started that can only be changed before parsing has started. This is (currently) only raised by `UseForeignDTD()`.

xml.parsers.expat.errors.XML_ERROR_UNBOUND_PREFIX
: An undeclared prefix was found when namespace processing was enabled.

xml.parsers.expat.errors.XML_ERROR_UNDECLARING_PREFIX
: The document attempted to remove the namespace declaration associated with a prefix.

xml.parsers.expat.errors.XML_ERROR_INCOMPLETE_PE
: A parameter entity contained incomplete markup.

xml.parsers.expat.errors.XML_ERROR_XML_DECL
: The document contained no document element at all.

xml.parsers.expat.errors.XML_ERROR_TEXT_DECL
: There was an error parsing a text declaration in an external entity.

xml.parsers.expat.errors.XML_ERROR_PUBLICID
: Characters were found in the public id that are not allowed.

xml.parsers.expat.errors.XML_ERROR_SUSPENDED
: The requested operation was made on a suspended parser, but isn't allowed. This includes attempts to provide additional input or to stop the parser.

xml.parsers.expat.errors.XML_ERROR_NOT_SUSPENDED
: An attempt to resume the parser was made when the parser had not been suspended.

xml.parsers.expat.errors.XML_ERROR_ABORTED
: This should not be reported to Python applications.

xml.parsers.expat.errors.XML_ERROR_FINISHED
: The requested operation was made on a parser which was finished parsing input, but isn't allowed. This includes attempts to provide additional input or to stop the parser.

xml.parsers.expat.errors.XML_ERROR_SUSPEND_PE

CHAPTER

TWENTYTWO

INTERNET PROTOCOLS AND SUPPORT

The modules described in this chapter implement Internet protocols and support for related technology. They are all implemented in Python. Most of these modules require the presence of the system-dependent module *socket*, which is currently supported on most popular platforms. Here is an overview:

22.1 webbrowser — Convenient Web-browser controller

Source code: Lib/webbrowser.py

The *webbrowser* module provides a high-level interface to allow displaying Web-based documents to users. Under most circumstances, simply calling the *open()* function from this module will do the right thing.

Under Unix, graphical browsers are preferred under X11, but text-mode browsers will be used if graphical browsers are not available or an X11 display isn't available. If text-mode browsers are used, the calling process will block until the user exits the browser.

If the environment variable BROWSER exists, it is interpreted as the *os.pathsep*-separated list of browsers to try ahead of the platform defaults. When the value of a list part contains the string %s, then it is interpreted as a literal browser command line to be used with the argument URL substituted for %s; if the part does not contain %s, it is simply interpreted as the name of the browser to launch.[1]

For non-Unix platforms, or when a remote browser is available on Unix, the controlling process will not wait for the user to finish with the browser, but allow the remote browser to maintain its own windows on the display. If remote browsers are not available on Unix, the controlling process will launch a new browser and wait.

The script **webbrowser** can be used as a command-line interface for the module. It accepts a URL as the argument. It accepts the following optional parameters: -n opens the URL in a new browser window, if possible; -t opens the URL in a new browser page ("tab"). The options are, naturally, mutually exclusive. Usage example:

```
python -m webbrowser -t "http://www.python.org"
```

The following exception is defined:

exception webbrowser.Error
Exception raised when a browser control error occurs.

The following functions are defined:

webbrowser.open(*url*, *new=0*, *autoraise=True*)
Display *url* using the default browser. If *new* is 0, the *url* is opened in the same browser window if possible. If *new* is 1, a new browser window is opened if possible. If *new* is 2, a new browser page

[1] Executables named here without a full path will be searched in the directories given in the PATH environment variable.

("tab") is opened if possible. If *autoraise* is `True`, the window is raised if possible (note that under many window managers this will occur regardless of the setting of this variable).

Note that on some platforms, trying to open a filename using this function, may work and start the operating system's associated program. However, this is neither supported nor portable.

`webbrowser.open_new(`*url*`)`
Open *url* in a new window of the default browser, if possible, otherwise, open *url* in the only browser window.

`webbrowser.open_new_tab(`*url*`)`
Open *url* in a new page ("tab") of the default browser, if possible, otherwise equivalent to *open_new()*.

`webbrowser.get(`*using=None*`)`
Return a controller object for the browser type *using*. If *using* is `None`, return a controller for a default browser appropriate to the caller's environment.

`webbrowser.register(`*name*, *constructor*, *instance=None*, ***, *preferred=False*`)`
Register the browser type *name*. Once a browser type is registered, the *get()* function can return a controller for that browser type. If *instance* is not provided, or is `None`, *constructor* will be called without parameters to create an instance when needed. If *instance* is provided, *constructor* will never be called, and may be `None`.

Setting *preferred* to `True` makes this browser a preferred result for a *get()* call with no argument. Otherwise, this entry point is only useful if you plan to either set the `BROWSER` variable or call *get()* with a nonempty argument matching the name of a handler you declare.

Changed in version 3.7: *preferred* keyword-only parameter was added.

A number of browser types are predefined. This table gives the type names that may be passed to the *get()* function and the corresponding instantiations for the controller classes, all defined in this module.

Type Name	Class Name	Notes
`'mozilla'`	`Mozilla('mozilla')`	
`'firefox'`	`Mozilla('mozilla')`	
`'netscape'`	`Mozilla('netscape')`	
`'galeon'`	`Galeon('galeon')`	
`'epiphany'`	`Galeon('epiphany')`	
`'skipstone'`	`BackgroundBrowser('skipstone')`	
`'kfmclient'`	`Konqueror()`	(1)
`'konqueror'`	`Konqueror()`	(1)
`'kfm'`	`Konqueror()`	(1)
`'mosaic'`	`BackgroundBrowser('mosaic')`	
`'opera'`	`Opera()`	
`'grail'`	`Grail()`	
`'links'`	`GenericBrowser('links')`	
`'elinks'`	`Elinks('elinks')`	
`'lynx'`	`GenericBrowser('lynx')`	
`'w3m'`	`GenericBrowser('w3m')`	
`'windows-default'`	`WindowsDefault`	(2)
`'macosx'`	`MacOSX('default')`	(3)
`'safari'`	`MacOSX('safari')`	(3)
`'google-chrome'`	`Chrome('google-chrome')`	
`'chrome'`	`Chrome('chrome')`	
`'chromium'`	`Chromium('chromium')`	
`'chromium-browser'`	`Chromium('chromium-browser')`	

Notes:

1. "Konqueror" is the file manager for the KDE desktop environment for Unix, and only makes sense to use if KDE is running. Some way of reliably detecting KDE would be nice; the `KDEDIR` variable is not sufficient. Note also that the name "kfm" is used even when using the **konqueror** command with KDE 2 — the implementation selects the best strategy for running Konqueror.
2. Only on Windows platforms.
3. Only on Mac OS X platform.

New in version 3.3: Support for Chrome/Chromium has been added.

Here are some simple examples:

```
url = 'http://docs.python.org/'

# Open URL in a new tab, if a browser window is already open.
webbrowser.open_new_tab(url)

# Open URL in new window, raising the window if possible.
webbrowser.open_new(url)
```

22.1.1 Browser Controller Objects

Browser controllers provide these methods which parallel three of the module-level convenience functions:

`controller.open(`*url*, *new=0*, *autoraise=True*`)`
Display *url* using the browser handled by this controller. If *new* is 1, a new browser window is opened if possible. If *new* is 2, a new browser page ("tab") is opened if possible.

`controller.open_new(`*url*`)`
Open *url* in a new window of the browser handled by this controller, if possible, otherwise, open *url* in the only browser window. Alias *open_new()*.

`controller.open_new_tab(`*url*`)`
Open *url* in a new page ("tab") of the browser handled by this controller, if possible, otherwise equivalent to *open_new()*.

22.2 cgi — Common Gateway Interface support

Source code: Lib/cgi.py

Support module for Common Gateway Interface (CGI) scripts.

This module defines a number of utilities for use by CGI scripts written in Python.

22.2.1 Introduction

A CGI script is invoked by an HTTP server, usually to process user input submitted through an HTML `<FORM>` or `<ISINDEX>` element.

Most often, CGI scripts live in the server's special `cgi-bin` directory. The HTTP server places all sorts of information about the request (such as the client's hostname, the requested URL, the query string, and lots of other goodies) in the script's shell environment, executes the script, and sends the script's output back to the client.

The script's input is connected to the client too, and sometimes the form data is read this way; at other times the form data is passed via the "query string" part of the URL. This module is intended to take care of the different cases and provide a simpler interface to the Python script. It also provides a number of utilities that help in debugging scripts, and the latest addition is support for file uploads from a form (if your browser supports it).

The output of a CGI script should consist of two sections, separated by a blank line. The first section contains a number of headers, telling the client what kind of data is following. Python code to generate a minimal header section looks like this:

```
print("Content-Type: text/html")    # HTML is following
print()                             # blank line, end of headers
```

The second section is usually HTML, which allows the client software to display nicely formatted text with header, in-line images, etc. Here's Python code that prints a simple piece of HTML:

```
print("<TITLE>CGI script output</TITLE>")
print("<H1>This is my first CGI script</H1>")
print("Hello, world!")
```

22.2.2 Using the cgi module

Begin by writing `import cgi`.

When you write a new script, consider adding these lines:

```
import cgitb
cgitb.enable()
```

This activates a special exception handler that will display detailed reports in the Web browser if any errors occur. If you'd rather not show the guts of your program to users of your script, you can have the reports saved to files instead, with code like this:

```
import cgitb
cgitb.enable(display=0, logdir="/path/to/logdir")
```

It's very helpful to use this feature during script development. The reports produced by *cgitb* provide information that can save you a lot of time in tracking down bugs. You can always remove the `cgitb` line later when you have tested your script and are confident that it works correctly.

To get at submitted form data, use the `FieldStorage` class. If the form contains non-ASCII characters, use the *encoding* keyword parameter set to the value of the encoding defined for the document. It is usually contained in the META tag in the HEAD section of the HTML document or by the *Content-Type* header). This reads the form contents from the standard input or the environment (depending on the value of various environment variables set according to the CGI standard). Since it may consume standard input, it should be instantiated only once.

The `FieldStorage` instance can be indexed like a Python dictionary. It allows membership testing with the `in` operator, and also supports the standard dictionary method *keys()* and the built-in function *len()*. Form fields containing empty strings are ignored and do not appear in the dictionary; to keep such values, provide a true value for the optional *keep_blank_values* keyword parameter when creating the `FieldStorage` instance.

For instance, the following code (which assumes that the *Content-Type* header and blank line have already been printed) checks that the fields `name` and `addr` are both set to a non-empty string:

```
form = cgi.FieldStorage()
if "name" not in form or "addr" not in form:
    print("<H1>Error</H1>")
    print("Please fill in the name and addr fields.")
    return
print("<p>name:", form["name"].value)
print("<p>addr:", form["addr"].value)
...further form processing here...
```

Here the fields, accessed through `form[key]`, are themselves instances of `FieldStorage` (or `MiniFieldStorage`, depending on the form encoding). The `value` attribute of the instance yields the string value of the field. The `getvalue()` method returns this string value directly; it also accepts an optional second argument as a default to return if the requested key is not present.

If the submitted form data contains more than one field with the same name, the object retrieved by `form[key]` is not a `FieldStorage` or `MiniFieldStorage` instance but a list of such instances. Similarly, in this situation, `form.getvalue(key)` would return a list of strings. If you expect this possibility (when your HTML form contains multiple fields with the same name), use the *`getlist()`* method, which always returns a list of values (so that you do not need to special-case the single item case). For example, this code concatenates any number of username fields, separated by commas:

```
value = form.getlist("username")
usernames = ",".join(value)
```

If a field represents an uploaded file, accessing the value via the `value` attribute or the `getvalue()` method reads the entire file in memory as bytes. This may not be what you want. You can test for an uploaded file by testing either the `filename` attribute or the `file` attribute. You can then read the data from the `file` attribute before it is automatically closed as part of the garbage collection of the `FieldStorage` instance (the *`read()`* and *`readline()`* methods will return bytes):

```
fileitem = form["userfile"]
if fileitem.file:
    # It's an uploaded file; count lines
    linecount = 0
    while True:
        line = fileitem.file.readline()
        if not line: break
        linecount = linecount + 1
```

`FieldStorage` objects also support being used in a `with` statement, which will automatically close them when done.

If an error is encountered when obtaining the contents of an uploaded file (for example, when the user interrupts the form submission by clicking on a Back or Cancel button) the `done` attribute of the object for the field will be set to the value -1.

The file upload draft standard entertains the possibility of uploading multiple files from one field (using a recursive *`multipart/*`* encoding). When this occurs, the item will be a dictionary-like `FieldStorage` item. This can be determined by testing its `type` attribute, which should be *`multipart/form-data`* (or perhaps another MIME type matching *`multipart/*`*). In this case, it can be iterated over recursively just like the top-level form object.

When a form is submitted in the "old" format (as the query string or as a single data part of type *`application/x-www-form-urlencoded`*), the items will actually be instances of the class `MiniFieldStorage`. In this case, the `list`, `file`, and `filename` attributes are always `None`.

A form submitted via POST that also has a query string will contain both `FieldStorage` and `MiniFieldStorage` items.

Changed in version 3.4: The `file` attribute is automatically closed upon the garbage collection of the creating `FieldStorage` instance.

Changed in version 3.5: Added support for the context management protocol to the `FieldStorage` class.

22.2.3 Higher Level Interface

The previous section explains how to read CGI form data using the `FieldStorage` class. This section describes a higher level interface which was added to this class to allow one to do it in a more readable and intuitive way. The interface doesn't make the techniques described in previous sections obsolete — they are still useful to process file uploads efficiently, for example.

The interface consists of two simple methods. Using the methods you can process form data in a generic way, without the need to worry whether only one or more values were posted under one name.

In the previous section, you learned to write following code anytime you expected a user to post more than one value under one name:

```
item = form.getvalue("item")
if isinstance(item, list):
    # The user is requesting more than one item.
else:
    # The user is requesting only one item.
```

This situation is common for example when a form contains a group of multiple checkboxes with the same name:

```
<input type="checkbox" name="item" value="1" />
<input type="checkbox" name="item" value="2" />
```

In most situations, however, there's only one form control with a particular name in a form and then you expect and need only one value associated with this name. So you write a script containing for example this code:

```
user = form.getvalue("user").upper()
```

The problem with the code is that you should never expect that a client will provide valid input to your scripts. For example, if a curious user appends another `user=foo` pair to the query string, then the script would crash, because in this situation the `getvalue("user")` method call returns a list instead of a string. Calling the *upper()* method on a list is not valid (since lists do not have a method of this name) and results in an *AttributeError* exception.

Therefore, the appropriate way to read form data values was to always use the code which checks whether the obtained value is a single value or a list of values. That's annoying and leads to less readable scripts.

A more convenient approach is to use the methods *getfirst()* and *getlist()* provided by this higher level interface.

`FieldStorage.getfirst`(*name*, *default=None*)

This method always returns only one value associated with form field *name*. The method returns only the first value in case that more values were posted under such name. Please note that the order in which the values are received may vary from browser to browser and should not be counted on.[1] If no such form field or value exists then the method returns the value specified by the optional parameter *default*. This parameter defaults to `None` if not specified.

[1] Note that some recent versions of the HTML specification do state what order the field values should be supplied in, but knowing whether a request was received from a conforming browser, or even from a browser at all, is tedious and error-prone.

FieldStorage.getlist(*name*)
: This method always returns a list of values associated with form field *name*. The method returns an empty list if no such form field or value exists for *name*. It returns a list consisting of one item if only one such value exists.

Using these methods you can write nice compact code:

```
import cgi
form = cgi.FieldStorage()
user = form.getfirst("user", "").upper()    # This way it's safe.
for item in form.getlist("item"):
    do_something(item)
```

22.2.4 Functions

These are useful if you want more control, or if you want to employ some of the algorithms implemented in this module in other circumstances.

cgi.parse(*fp=None*, *environ=os.environ*, *keep_blank_values=False*, *strict_parsing=False*)
: Parse a query in the environment or from a file (the file defaults to `sys.stdin`). The *keep_blank_values* and *strict_parsing* parameters are passed to *urllib.parse.parse_qs()* unchanged.

cgi.parse_qs(*qs*, *keep_blank_values=False*, *strict_parsing=False*)
: This function is deprecated in this module. Use *urllib.parse.parse_qs()* instead. It is maintained here only for backward compatibility.

cgi.parse_qsl(*qs*, *keep_blank_values=False*, *strict_parsing=False*)
: This function is deprecated in this module. Use *urllib.parse.parse_qsl()* instead. It is maintained here only for backward compatibility.

cgi.parse_multipart(*fp*, *pdict*, *encoding="utf-8"*, *errors="replace"*)
: Parse input of type *multipart/form-data* (for file uploads). Arguments are *fp* for the input file, *pdict* for a dictionary containing other parameters in the *Content-Type* header, and *encoding*, the request encoding.

  Returns a dictionary just like *urllib.parse.parse_qs()*: keys are the field names, each value is a list of values for that field. For non-file fields, the value is a list of strings.

  This is easy to use but not much good if you are expecting megabytes to be uploaded — in that case, use the `FieldStorage` class instead which is much more flexible.

  Changed in version 3.7: Added the *encoding* and *errors* parameters. For non-file fields, the value is now a list of strings, not bytes.

cgi.parse_header(*string*)
: Parse a MIME header (such as *Content-Type*) into a main value and a dictionary of parameters.

cgi.test()
: Robust test CGI script, usable as main program. Writes minimal HTTP headers and formats all information provided to the script in HTML form.

cgi.print_environ()
: Format the shell environment in HTML.

cgi.print_form(*form*)
: Format a form in HTML.

cgi.print_directory()
: Format the current directory in HTML.

cgi.print_environ_usage()
: Print a list of useful (used by CGI) environment variables in HTML.

cgi.escape(*s*, *quote=False*)

Convert the characters '&', '<' and '>' in string *s* to HTML-safe sequences. Use this if you need to display text that might contain such characters in HTML. If the optional flag *quote* is true, the quotation mark character (") is also translated; this helps for inclusion in an HTML attribute value delimited by double quotes, as in <a href="...">. Note that single quotes are never translated.

Deprecated since version 3.2: This function is unsafe because *quote* is false by default, and therefore deprecated. Use *html.escape()* instead.

22.2.5 Caring about security

There's one important rule: if you invoke an external program (via the *os.system()* or *os.popen()* functions. or others with similar functionality), make very sure you don't pass arbitrary strings received from the client to the shell. This is a well-known security hole whereby clever hackers anywhere on the Web can exploit a gullible CGI script to invoke arbitrary shell commands. Even parts of the URL or field names cannot be trusted, since the request doesn't have to come from your form!

To be on the safe side, if you must pass a string gotten from a form to a shell command, you should make sure the string contains only alphanumeric characters, dashes, underscores, and periods.

22.2.6 Installing your CGI script on a Unix system

Read the documentation for your HTTP server and check with your local system administrator to find the directory where CGI scripts should be installed; usually this is in a directory cgi-bin in the server tree.

Make sure that your script is readable and executable by "others"; the Unix file mode should be 0o755 octal (use chmod 0755 filename). Make sure that the first line of the script contains #! starting in column 1 followed by the pathname of the Python interpreter, for instance:

```
#!/usr/local/bin/python
```

Make sure the Python interpreter exists and is executable by "others".

Make sure that any files your script needs to read or write are readable or writable, respectively, by "others" — their mode should be 0o644 for readable and 0o666 for writable. This is because, for security reasons, the HTTP server executes your script as user "nobody", without any special privileges. It can only read (write, execute) files that everybody can read (write, execute). The current directory at execution time is also different (it is usually the server's cgi-bin directory) and the set of environment variables is also different from what you get when you log in. In particular, don't count on the shell's search path for executables (PATH) or the Python module search path (PYTHONPATH) to be set to anything interesting.

If you need to load modules from a directory which is not on Python's default module search path, you can change the path in your script, before importing other modules. For example:

```
import sys
sys.path.insert(0, "/usr/home/joe/lib/python")
sys.path.insert(0, "/usr/local/lib/python")
```

(This way, the directory inserted last will be searched first!)

Instructions for non-Unix systems will vary; check your HTTP server's documentation (it will usually have a section on CGI scripts).

22.2.7 Testing your CGI script

Unfortunately, a CGI script will generally not run when you try it from the command line, and a script that works perfectly from the command line may fail mysteriously when run from the server. There's one reason why you should still test your script from the command line: if it contains a syntax error, the Python interpreter won't execute it at all, and the HTTP server will most likely send a cryptic error to the client.

Assuming your script has no syntax errors, yet it does not work, you have no choice but to read the next section.

22.2.8 Debugging CGI scripts

First of all, check for trivial installation errors — reading the section above on installing your CGI script carefully can save you a lot of time. If you wonder whether you have understood the installation procedure correctly, try installing a copy of this module file (`cgi.py`) as a CGI script. When invoked as a script, the file will dump its environment and the contents of the form in HTML form. Give it the right mode etc, and send it a request. If it's installed in the standard `cgi-bin` directory, it should be possible to send it a request by entering a URL into your browser of the form:

```
http://yourhostname/cgi-bin/cgi.py?name=Joe+Blow&addr=At+Home
```

If this gives an error of type 404, the server cannot find the script – perhaps you need to install it in a different directory. If it gives another error, there's an installation problem that you should fix before trying to go any further. If you get a nicely formatted listing of the environment and form content (in this example, the fields should be listed as "addr" with value "At Home" and "name" with value "Joe Blow"), the `cgi.py` script has been installed correctly. If you follow the same procedure for your own script, you should now be able to debug it.

The next step could be to call the *cgi* module's *test()* function from your script: replace its main code with the single statement

```
cgi.test()
```

This should produce the same results as those gotten from installing the `cgi.py` file itself.

When an ordinary Python script raises an unhandled exception (for whatever reason: of a typo in a module name, a file that can't be opened, etc.), the Python interpreter prints a nice traceback and exits. While the Python interpreter will still do this when your CGI script raises an exception, most likely the traceback will end up in one of the HTTP server's log files, or be discarded altogether.

Fortunately, once you have managed to get your script to execute *some* code, you can easily send tracebacks to the Web browser using the *cgitb* module. If you haven't done so already, just add the lines:

```
import cgitb
cgitb.enable()
```

to the top of your script. Then try running it again; when a problem occurs, you should see a detailed report that will likely make apparent the cause of the crash.

If you suspect that there may be a problem in importing the *cgitb* module, you can use an even more robust approach (which only uses built-in modules):

```
import sys
sys.stderr = sys.stdout
print("Content-Type: text/plain")
print()
...your code here...
```

This relies on the Python interpreter to print the traceback. The content type of the output is set to plain text, which disables all HTML processing. If your script works, the raw HTML will be displayed by your client. If it raises an exception, most likely after the first two lines have been printed, a traceback will be displayed. Because no HTML interpretation is going on, the traceback will be readable.

22.2.9 Common problems and solutions

- Most HTTP servers buffer the output from CGI scripts until the script is completed. This means that it is not possible to display a progress report on the client's display while the script is running.
- Check the installation instructions above.
- Check the HTTP server's log files. (`tail -f logfile` in a separate window may be useful!)
- Always check a script for syntax errors first, by doing something like `python script.py`.
- If your script does not have any syntax errors, try adding `import cgitb; cgitb.enable()` to the top of the script.
- When invoking external programs, make sure they can be found. Usually, this means using absolute path names — `PATH` is usually not set to a very useful value in a CGI script.
- When reading or writing external files, make sure they can be read or written by the userid under which your CGI script will be running: this is typically the userid under which the web server is running, or some explicitly specified userid for a web server's `suexec` feature.
- Don't try to give a CGI script a set-uid mode. This doesn't work on most systems, and is a security liability as well.

22.3 `cgitb` — Traceback manager for CGI scripts

Source code: Lib/cgitb.py

The *cgitb* module provides a special exception handler for Python scripts. (Its name is a bit misleading. It was originally designed to display extensive traceback information in HTML for CGI scripts. It was later generalized to also display this information in plain text.) After this module is activated, if an uncaught exception occurs, a detailed, formatted report will be displayed. The report includes a traceback showing excerpts of the source code for each level, as well as the values of the arguments and local variables to currently running functions, to help you debug the problem. Optionally, you can save this information to a file instead of sending it to the browser.

To enable this feature, simply add this to the top of your CGI script:

```
import cgitb
cgitb.enable()
```

The options to the *enable()* function control whether the report is displayed in the browser and whether the report is logged to a file for later analysis.

`cgitb.enable`(*display=1*, *logdir=None*, *context=5*, *format="html"*)

This function causes the *cgitb* module to take over the interpreter's default handling for exceptions by setting the value of *sys.excepthook*.

The optional argument *display* defaults to `1` and can be set to `0` to suppress sending the traceback to the browser. If the argument *logdir* is present, the traceback reports are written to files. The value of *logdir* should be a directory where these files will be placed. The optional argument *context* is the number of lines of context to display around the current line of source code in the traceback; this

defaults to 5. If the optional argument *format* is "html", the output is formatted as HTML. Any other value forces plain text output. The default value is "html".

cgitb.**text**(*info*, *context=5*)
: This function handles the exception described by *info* (a 3-tuple containing the result of *sys.exc_info()*), formatting its traceback as text and returning the result as a string. The optional argument *context* is the number of lines of context to display around the current line of source code in the traceback; this defaults to 5.

cgitb.**html**(*info*, *context=5*)
: This function handles the exception described by *info* (a 3-tuple containing the result of *sys.exc_info()*), formatting its traceback as HTML and returning the result as a string. The optional argument *context* is the number of lines of context to display around the current line of source code in the traceback; this defaults to 5.

cgitb.**handler**(*info=None*)
: This function handles an exception using the default settings (that is, show a report in the browser, but don't log to a file). This can be used when you've caught an exception and want to report it using *cgitb*. The optional *info* argument should be a 3-tuple containing an exception type, exception value, and traceback object, exactly like the tuple returned by *sys.exc_info()*. If the *info* argument is not supplied, the current exception is obtained from *sys.exc_info()*.

22.4 wsgiref — WSGI Utilities and Reference Implementation

The Web Server Gateway Interface (WSGI) is a standard interface between web server software and web applications written in Python. Having a standard interface makes it easy to use an application that supports WSGI with a number of different web servers.

Only authors of web servers and programming frameworks need to know every detail and corner case of the WSGI design. You don't need to understand every detail of WSGI just to install a WSGI application or to write a web application using an existing framework.

wsgiref is a reference implementation of the WSGI specification that can be used to add WSGI support to a web server or framework. It provides utilities for manipulating WSGI environment variables and response headers, base classes for implementing WSGI servers, a demo HTTP server that serves WSGI applications, and a validation tool that checks WSGI servers and applications for conformance to the WSGI specification (**PEP 3333**).

See wsgi.readthedocs.io for more information about WSGI, and links to tutorials and other resources.

22.4.1 wsgiref.util – WSGI environment utilities

This module provides a variety of utility functions for working with WSGI environments. A WSGI environment is a dictionary containing HTTP request variables as described in **PEP 3333**. All of the functions taking an *environ* parameter expect a WSGI-compliant dictionary to be supplied; please see **PEP 3333** for a detailed specification.

wsgiref.util.**guess_scheme**(*environ*)
: Return a guess for whether wsgi.url_scheme should be "http" or "https", by checking for a HTTPS environment variable in the *environ* dictionary. The return value is a string.

  This function is useful when creating a gateway that wraps CGI or a CGI-like protocol such as FastCGI. Typically, servers providing such protocols will include a HTTPS variable with a value of "1" "yes", or "on" when a request is received via SSL. So, this function returns "https" if such a value is found, and "http" otherwise.

wsgiref.util.request_uri(*environ*, *include_query=True*)
Return the full request URI, optionally including the query string, using the algorithm found in the "URL Reconstruction" section of **PEP 3333**. If *include_query* is false, the query string is not included in the resulting URI.

wsgiref.util.application_uri(*environ*)
Similar to *request_uri()*, except that the PATH_INFO and QUERY_STRING variables are ignored. The result is the base URI of the application object addressed by the request.

wsgiref.util.shift_path_info(*environ*)
Shift a single name from PATH_INFO to SCRIPT_NAME and return the name. The *environ* dictionary is *modified* in-place; use a copy if you need to keep the original PATH_INFO or SCRIPT_NAME intact.

If there are no remaining path segments in PATH_INFO, None is returned.

Typically, this routine is used to process each portion of a request URI path, for example to treat the path as a series of dictionary keys. This routine modifies the passed-in environment to make it suitable for invoking another WSGI application that is located at the target URI. For example, if there is a WSGI application at /foo, and the request URI path is /foo/bar/baz, and the WSGI application at /foo calls *shift_path_info()*, it will receive the string "bar", and the environment will be updated to be suitable for passing to a WSGI application at /foo/bar. That is, SCRIPT_NAME will change from /foo to /foo/bar, and PATH_INFO will change from /bar/baz to /baz.

When PATH_INFO is just a "/", this routine returns an empty string and appends a trailing slash to SCRIPT_NAME, even though empty path segments are normally ignored, and SCRIPT_NAME doesn't normally end in a slash. This is intentional behavior, to ensure that an application can tell the difference between URIs ending in /x from ones ending in /x/ when using this routine to do object traversal.

wsgiref.util.setup_testing_defaults(*environ*)
Update *environ* with trivial defaults for testing purposes.

This routine adds various parameters required for WSGI, including HTTP_HOST, SERVER_NAME, SERVER_PORT, REQUEST_METHOD, SCRIPT_NAME, PATH_INFO, and all of the **PEP 3333**-defined wsgi.* variables. It only supplies default values, and does not replace any existing settings for these variables.

This routine is intended to make it easier for unit tests of WSGI servers and applications to set up dummy environments. It should NOT be used by actual WSGI servers or applications, since the data is fake!

Example usage:

```
from wsgiref.util import setup_testing_defaults
from wsgiref.simple_server import make_server

# A relatively simple WSGI application. It's going to print out the
# environment dictionary after being updated by setup_testing_defaults
def simple_app(environ, start_response):
    setup_testing_defaults(environ)

    status = '200 OK'
    headers = [('Content-type', 'text/plain; charset=utf-8')]

    start_response(status, headers)

    ret = [("%s: %s\n" % (key, value)).encode("utf-8")
           for key, value in environ.items()]
    return ret

with make_server('', 8000, simple_app) as httpd:
    print("Serving on port 8000...")
    httpd.serve_forever()
```

In addition to the environment functions above, the *wsgiref.util* module also provides these miscellaneous utilities:

wsgiref.util.is_hop_by_hop(*header_name*)
Return true if 'header_name' is an HTTP/1.1 "Hop-by-Hop" header, as defined by **RFC 2616**.

class wsgiref.util.FileWrapper(*filelike*, *blksize=8192*)
A wrapper to convert a file-like object to an *iterator*. The resulting objects support both `__getitem__()` and `__iter__()` iteration styles, for compatibility with Python 2.1 and Jython. As the object is iterated over, the optional *blksize* parameter will be repeatedly passed to the *filelike* object's `read()` method to obtain bytestrings to yield. When `read()` returns an empty bytestring, iteration is ended and is not resumable.

If *filelike* has a `close()` method, the returned object will also have a `close()` method, and it will invoke the *filelike* object's `close()` method when called.

Example usage:

```
from io import StringIO
from wsgiref.util import FileWrapper

# We're using a StringIO-buffer for as the file-like object
filelike = StringIO("This is an example file-like object"*10)
wrapper = FileWrapper(filelike, blksize=5)

for chunk in wrapper:
    print(chunk)
```

22.4.2 wsgiref.headers – WSGI response header tools

This module provides a single class, *Headers*, for convenient manipulation of WSGI response headers using a mapping-like interface.

class wsgiref.headers.Headers([*headers*])
Create a mapping-like object wrapping *headers*, which must be a list of header name/value tuples as described in **PEP 3333**. The default value of *headers* is an empty list.

Headers objects support typical mapping operations including `__getitem__()`, `get()`, `__setitem__()`, `setdefault()`, `__delitem__()` and `__contains__()`. For each of these methods, the key is the header name (treated case-insensitively), and the value is the first value associated with that header name. Setting a header deletes any existing values for that header, then adds a new value at the end of the wrapped header list. Headers' existing order is generally maintained, with new headers added to the end of the wrapped list.

Unlike a dictionary, *Headers* objects do not raise an error when you try to get or delete a key that isn't in the wrapped header list. Getting a nonexistent header just returns `None`, and deleting a nonexistent header does nothing.

Headers objects also support `keys()`, `values()`, and `items()` methods. The lists returned by `keys()` and `items()` can include the same key more than once if there is a multi-valued header. The `len()` of a *Headers* object is the same as the length of its `items()`, which is the same as the length of the wrapped header list. In fact, the `items()` method just returns a copy of the wrapped header list.

Calling `bytes()` on a *Headers* object returns a formatted bytestring suitable for transmission as HTTP response headers. Each header is placed on a line with its value, separated by a colon and a space. Each line is terminated by a carriage return and line feed, and the bytestring is terminated with a blank line.

In addition to their mapping interface and formatting features, *Headers* objects also have the following methods for querying and adding multi-valued headers, and for adding headers with MIME parameters:

get_all(*name*)
Return a list of all the values for the named header.

The returned list will be sorted in the order they appeared in the original header list or were added to this instance, and may contain duplicates. Any fields deleted and re-inserted are always appended to the header list. If no fields exist with the given name, returns an empty list.

add_header(*name*, *value*, ***_params*)
Add a (possibly multi-valued) header, with optional MIME parameters specified via keyword arguments.

name is the header field to add. Keyword arguments can be used to set MIME parameters for the header field. Each parameter must be a string or `None`. Underscores in parameter names are converted to dashes, since dashes are illegal in Python identifiers, but many MIME parameter names include dashes. If the parameter value is a string, it is added to the header value parameters in the form `name="value"`. If it is `None`, only the parameter name is added. (This is used for MIME parameters without a value.) Example usage:

```
h.add_header('content-disposition', 'attachment', filename='bud.gif')
```

The above will add a header that looks like this:

```
Content-Disposition: attachment; filename="bud.gif"
```

Changed in version 3.5: *headers* parameter is optional.

22.4.3 wsgiref.simple_server – a simple WSGI HTTP server

This module implements a simple HTTP server (based on *http.server*) that serves WSGI applications. Each server instance serves a single WSGI application on a given host and port. If you want to serve multiple applications on a single host and port, you should create a WSGI application that parses `PATH_INFO` to select which application to invoke for each request. (E.g., using the `shift_path_info()` function from *wsgiref.util*.)

wsgiref.simple_server.make_server(*host*, *port*, *app*, *server_class=WSGIServer*, *handler_class=WSGIRequestHandler*)
Create a new WSGI server listening on *host* and *port*, accepting connections for *app*. The return value is an instance of the supplied *server_class*, and will process requests using the specified *handler_class*. *app* must be a WSGI application object, as defined by **PEP 3333**.

Example usage:

```
from wsgiref.simple_server import make_server, demo_app

with make_server('', 8000, demo_app) as httpd:
    print("Serving HTTP on port 8000...")

    # Respond to requests until process is killed
    httpd.serve_forever()

    # Alternative: serve one request, then exit
    httpd.handle_request()
```

wsgiref.simple_server.demo_app(*environ*, *start_response*)
This function is a small but complete WSGI application that returns a text page containing the

message "Hello world!" and a list of the key/value pairs provided in the *environ* parameter. It's useful for verifying that a WSGI server (such as *wsgiref.simple_server*) is able to run a simple WSGI application correctly.

class wsgiref.simple_server.WSGIServer(*server_address*, *RequestHandlerClass*)
Create a *WSGIServer* instance. *server_address* should be a `(host,port)` tuple, and *RequestHandlerClass* should be the subclass of *http.server.BaseHTTPRequestHandler* that will be used to process requests.

You do not normally need to call this constructor, as the *make_server()* function can handle all the details for you.

WSGIServer is a subclass of *http.server.HTTPServer*, so all of its methods (such as `serve_forever()` and `handle_request()`) are available. *WSGIServer* also provides these WSGI-specific methods:

set_app(*application*)
Sets the callable *application* as the WSGI application that will receive requests.

get_app()
Returns the currently-set application callable.

Normally, however, you do not need to use these additional methods, as *set_app()* is normally called by *make_server()*, and the *get_app()* exists mainly for the benefit of request handler instances.

class wsgiref.simple_server.WSGIRequestHandler(*request*, *client_address*, *server*)
Create an HTTP handler for the given *request* (i.e. a socket), *client_address* (a `(host,port)` tuple), and *server* (*WSGIServer* instance).

You do not need to create instances of this class directly; they are automatically created as needed by *WSGIServer* objects. You can, however, subclass this class and supply it as a *handler_class* to the *make_server()* function. Some possibly relevant methods for overriding in subclasses:

get_environ()
Returns a dictionary containing the WSGI environment for a request. The default implementation copies the contents of the *WSGIServer* object's `base_environ` dictionary attribute and then adds various headers derived from the HTTP request. Each call to this method should return a new dictionary containing all of the relevant CGI environment variables as specified in **PEP 3333**.

get_stderr()
Return the object that should be used as the `wsgi.errors` stream. The default implementation just returns `sys.stderr`.

handle()
Process the HTTP request. The default implementation creates a handler instance using a *wsgiref.handlers* class to implement the actual WSGI application interface.

22.4.4 wsgiref.validate — WSGI conformance checker

When creating new WSGI application objects, frameworks, servers, or middleware, it can be useful to validate the new code's conformance using *wsgiref.validate*. This module provides a function that creates WSGI application objects that validate communications between a WSGI server or gateway and a WSGI application object, to check both sides for protocol conformance.

Note that this utility does not guarantee complete **PEP 3333** compliance; an absence of errors from this module does not necessarily mean that errors do not exist. However, if this module does produce an error, then it is virtually certain that either the server or application is not 100% compliant.

This module is based on the `paste.lint` module from Ian Bicking's "Python Paste" library.

wsgiref.validate.validator(*application*)
Wrap *application* and return a new WSGI application object. The returned application will forward

all requests to the original *application*, and will check that both the *application* and the server invoking it are conforming to the WSGI specification and to **RFC 2616**.

Any detected nonconformance results in an *AssertionError* being raised; note, however, that how these errors are handled is server-dependent. For example, *wsgiref.simple_server* and other servers based on *wsgiref.handlers* (that don't override the error handling methods to do something else) will simply output a message that an error has occurred, and dump the traceback to `sys.stderr` or some other error stream.

This wrapper may also generate output using the *warnings* module to indicate behaviors that are questionable but which may not actually be prohibited by **PEP 3333**. Unless they are suppressed using Python command-line options or the *warnings* API, any such warnings will be written to `sys.stderr` (*not* `wsgi.errors`, unless they happen to be the same object).

Example usage:

```
from wsgiref.validate import validator
from wsgiref.simple_server import make_server

# Our callable object which is intentionally not compliant to the
# standard, so the validator is going to break
def simple_app(environ, start_response):
    status = '200 OK'  # HTTP Status
    headers = [('Content-type', 'text/plain')]  # HTTP Headers
    start_response(status, headers)

    # This is going to break because we need to return a list, and
    # the validator is going to inform us
    return b"Hello World"

# This is the application wrapped in a validator
validator_app = validator(simple_app)

with make_server('', 8000, validator_app) as httpd:
    print("Listening on port 8000....")
    httpd.serve_forever()
```

22.4.5 `wsgiref.handlers` – server/gateway base classes

This module provides base handler classes for implementing WSGI servers and gateways. These base classes handle most of the work of communicating with a WSGI application, as long as they are given a CGI-like environment, along with input, output, and error streams.

`class wsgiref.handlers.CGIHandler`

CGI-based invocation via `sys.stdin`, `sys.stdout`, `sys.stderr` and `os.environ`. This is useful when you have a WSGI application and want to run it as a CGI script. Simply invoke `CGIHandler().run(app)`, where `app` is the WSGI application object you wish to invoke.

This class is a subclass of *BaseCGIHandler* that sets `wsgi.run_once` to true, `wsgi.multithread` to false, and `wsgi.multiprocess` to true, and always uses *sys* and *os* to obtain the necessary CGI streams and environment.

`class wsgiref.handlers.IISCGIHandler`

A specialized alternative to *CGIHandler*, for use when deploying on Microsoft's IIS web server, without having set the config allowPathInfo option (IIS>=7) or metabase allowPathInfoForScriptMappings (IIS<7).

By default, IIS gives a `PATH_INFO` that duplicates the `SCRIPT_NAME` at the front, causing problems for WSGI applications that wish to implement routing. This handler strips any such duplicated path.

IIS can be configured to pass the correct `PATH_INFO`, but this causes another bug where `PATH_TRANSLATED` is wrong. Luckily this variable is rarely used and is not guaranteed by WSGI. On IIS<7, though, the setting can only be made on a vhost level, affecting all other script mappings, many of which break when exposed to the `PATH_TRANSLATED` bug. For this reason IIS<7 is almost never deployed with the fix. (Even IIS7 rarely uses it because there is still no UI for it.)

There is no way for CGI code to tell whether the option was set, so a separate handler class is provided. It is used in the same way as *CGIHandler*, i.e., by calling `IISCGIHandler().run(app)`, where `app` is the WSGI application object you wish to invoke.

New in version 3.2.

class wsgiref.handlers.BaseCGIHandler(*stdin*, *stdout*, *stderr*, *environ*, *multithread=True*, *multiprocess=False*)

Similar to *CGIHandler*, but instead of using the *sys* and *os* modules, the CGI environment and I/O streams are specified explicitly. The *multithread* and *multiprocess* values are used to set the `wsgi.multithread` and `wsgi.multiprocess` flags for any applications run by the handler instance.

This class is a subclass of *SimpleHandler* intended for use with software other than HTTP "origin servers". If you are writing a gateway protocol implementation (such as CGI, FastCGI, SCGI, etc.) that uses a `Status:` header to send an HTTP status, you probably want to subclass this instead of *SimpleHandler*.

class wsgiref.handlers.SimpleHandler(*stdin*, *stdout*, *stderr*, *environ*, *multithread=True*, *multiprocess=False*)

Similar to *BaseCGIHandler*, but designed for use with HTTP origin servers. If you are writing an HTTP server implementation, you will probably want to subclass this instead of *BaseCGIHandler*.

This class is a subclass of *BaseHandler*. It overrides the `__init__()`, `get_stdin()`, `get_stderr()`, `add_cgi_vars()`, `_write()`, and `_flush()` methods to support explicitly setting the environment and streams via the constructor. The supplied environment and streams are stored in the `stdin`, `stdout`, `stderr`, and `environ` attributes.

The *write()* method of *stdout* should write each chunk in full, like *io.BufferedIOBase*.

class wsgiref.handlers.BaseHandler

This is an abstract base class for running WSGI applications. Each instance will handle a single HTTP request, although in principle you could create a subclass that was reusable for multiple requests.

BaseHandler instances have only one method intended for external use:

run(*app*)

Run the specified WSGI application, *app*.

All of the other *BaseHandler* methods are invoked by this method in the process of running the application, and thus exist primarily to allow customizing the process.

The following methods MUST be overridden in a subclass:

_write(*data*)

Buffer the bytes *data* for transmission to the client. It's okay if this method actually transmits the data; *BaseHandler* just separates write and flush operations for greater efficiency when the underlying system actually has such a distinction.

_flush()

Force buffered data to be transmitted to the client. It's okay if this method is a no-op (i.e., if *_write()* actually sends the data).

get_stdin()

Return an input stream object suitable for use as the `wsgi.input` of the request currently being processed.

`get_stderr()`
Return an output stream object suitable for use as the `wsgi.errors` of the request currently being processed.

`add_cgi_vars()`
Insert CGI variables for the current request into the `environ` attribute.

Here are some other methods and attributes you may wish to override. This list is only a summary, however, and does not include every method that can be overridden. You should consult the docstrings and source code for additional information before attempting to create a customized *BaseHandler* subclass.

Attributes and methods for customizing the WSGI environment:

`wsgi_multithread`
The value to be used for the `wsgi.multithread` environment variable. It defaults to true in *BaseHandler*, but may have a different default (or be set by the constructor) in the other subclasses.

`wsgi_multiprocess`
The value to be used for the `wsgi.multiprocess` environment variable. It defaults to true in *BaseHandler*, but may have a different default (or be set by the constructor) in the other subclasses.

`wsgi_run_once`
The value to be used for the `wsgi.run_once` environment variable. It defaults to false in *BaseHandler*, but *CGIHandler* sets it to true by default.

`os_environ`
The default environment variables to be included in every request's WSGI environment. By default, this is a copy of `os.environ` at the time that *wsgiref.handlers* was imported, but subclasses can either create their own at the class or instance level. Note that the dictionary should be considered read-only, since the default value is shared between multiple classes and instances.

`server_software`
If the *origin_server* attribute is set, this attribute's value is used to set the default `SERVER_SOFTWARE` WSGI environment variable, and also to set a default `Server:` header in HTTP responses. It is ignored for handlers (such as *BaseCGIHandler* and *CGIHandler*) that are not HTTP origin servers.

Changed in version 3.3: The term "Python" is replaced with implementation specific term like "CPython", "Jython" etc.

`get_scheme()`
Return the URL scheme being used for the current request. The default implementation uses the `guess_scheme()` function from *wsgiref.util* to guess whether the scheme should be "http" or "https", based on the current request's `environ` variables.

`setup_environ()`
Set the `environ` attribute to a fully-populated WSGI environment. The default implementation uses all of the above methods and attributes, plus the *get_stdin()*, *get_stderr()*, and *add_cgi_vars()* methods and the *wsgi_file_wrapper* attribute. It also inserts a `SERVER_SOFTWARE` key if not present, as long as the *origin_server* attribute is a true value and the *server_software* attribute is set.

Methods and attributes for customizing exception handling:

`log_exception(`*exc_info*`)`
Log the *exc_info* tuple in the server log. *exc_info* is a `(type, value, traceback)` tuple. The default implementation simply writes the traceback to the request's `wsgi.errors` stream and

flushes it. Subclasses can override this method to change the format or retarget the output, mail the traceback to an administrator, or whatever other action may be deemed suitable.

traceback_limit
The maximum number of frames to include in tracebacks output by the default *log_exception()* method. If `None`, all frames are included.

error_output(*environ*, *start_response*)
This method is a WSGI application to generate an error page for the user. It is only invoked if an error occurs before headers are sent to the client.

This method can access the current error information using `sys.exc_info()`, and should pass that information to *start_response* when calling it (as described in the "Error Handling" section of **PEP 3333**).

The default implementation just uses the *error_status*, *error_headers*, and *error_body* attributes to generate an output page. Subclasses can override this to produce more dynamic error output.

Note, however, that it's not recommended from a security perspective to spit out diagnostics to any old user; ideally, you should have to do something special to enable diagnostic output, which is why the default implementation doesn't include any.

error_status
The HTTP status used for error responses. This should be a status string as defined in **PEP 3333**; it defaults to a 500 code and message.

error_headers
The HTTP headers used for error responses. This should be a list of WSGI response headers (`(name, value)` tuples), as described in **PEP 3333**. The default list just sets the content type to `text/plain`.

error_body
The error response body. This should be an HTTP response body bytestring. It defaults to the plain text, "A server error occurred. Please contact the administrator."

Methods and attributes for **PEP 3333**'s "Optional Platform-Specific File Handling" feature:

wsgi_file_wrapper
A `wsgi.file_wrapper` factory, or `None`. The default value of this attribute is the *wsgiref.util.FileWrapper* class.

sendfile()
Override to implement platform-specific file transmission. This method is called only if the application's return value is an instance of the class specified by the *wsgi_file_wrapper* attribute. It should return a true value if it was able to successfully transmit the file, so that the default transmission code will not be executed. The default implementation of this method just returns a false value.

Miscellaneous methods and attributes:

origin_server
This attribute should be set to a true value if the handler's *_write()* and *_flush()* are being used to communicate directly to the client, rather than via a CGI-like gateway protocol that wants the HTTP status in a special `Status:` header.

This attribute's default value is true in *BaseHandler*, but false in *BaseCGIHandler* and *CGIHandler*.

http_version
If *origin_server* is true, this string attribute is used to set the HTTP version of the response set to the client. It defaults to `"1.0"`.

wsgiref.handlers.read_environ()
: Transcode CGI variables from os.environ to PEP 3333 "bytes in unicode" strings, returning a new dictionary. This function is used by *CGIHandler* and *IISCGIHandler* in place of directly using os.environ, which is not necessarily WSGI-compliant on all platforms and web servers using Python 3 – specifically, ones where the OS's actual environment is Unicode (i.e. Windows), or ones where the environment is bytes, but the system encoding used by Python to decode it is anything other than ISO-8859-1 (e.g. Unix systems using UTF-8).

  If you are implementing a CGI-based handler of your own, you probably want to use this routine instead of just copying values out of os.environ directly.

  New in version 3.2.

22.4.6 Examples

This is a working "Hello World" WSGI application:

```
from wsgiref.simple_server import make_server

# Every WSGI application must have an application object - a callable
# object that accepts two arguments. For that purpose, we're going to
# use a function (note that you're not limited to a function, you can
# use a class for example). The first argument passed to the function
# is a dictionary containing CGI-style environment variables and the
# second variable is the callable object (see PEP 333).
def hello_world_app(environ, start_response):
    status = '200 OK'  # HTTP Status
    headers = [('Content-type', 'text/plain; charset=utf-8')]  # HTTP Headers
    start_response(status, headers)

    # The returned object is going to be printed
    return [b"Hello World"]

with make_server('', 8000, hello_world_app) as httpd:
    print("Serving on port 8000...")

    # Serve until process is killed
    httpd.serve_forever()
```

22.5 urllib — URL handling modules

Source code: Lib/urllib/

---

urllib is a package that collects several modules for working with URLs:

- *urllib.request* for opening and reading URLs
- *urllib.error* containing the exceptions raised by *urllib.request*
- *urllib.parse* for parsing URLs
- *urllib.robotparser* for parsing robots.txt files

22.6 urllib.request — Extensible library for opening URLs

Source code: Lib/urllib/request.py

The *urllib.request* module defines functions and classes which help in opening URLs (mostly HTTP) in a complex world — basic and digest authentication, redirections, cookies and more.

See also:

The Requests package is recommended for a higher-level HTTP client interface.

The *urllib.request* module defines the following functions:

urllib.request.urlopen(*url*, *data=None*[, *timeout*], ***, *cafile=None*, *capath=None*, *cadefault=False*, *context=None*)

Open the URL *url*, which can be either a string or a *Request* object.

data must be an object specifying additional data to be sent to the server, or `None` if no such data is needed. See *Request* for details.

urllib.request module uses HTTP/1.1 and includes `Connection:close` header in its HTTP requests.

The optional *timeout* parameter specifies a timeout in seconds for blocking operations like the connection attempt (if not specified, the global default timeout setting will be used). This actually only works for HTTP, HTTPS and FTP connections.

If *context* is specified, it must be a *ssl.SSLContext* instance describing the various SSL options. See *HTTPSConnection* for more details.

The optional *cafile* and *capath* parameters specify a set of trusted CA certificates for HTTPS requests. *cafile* should point to a single file containing a bundle of CA certificates, whereas *capath* should point to a directory of hashed certificate files. More information can be found in *ssl.SSLContext.load_verify_locations()*.

The *cadefault* parameter is ignored.

This function always returns an object which can work as a *context manager* and has methods such as

- `geturl()` — return the URL of the resource retrieved, commonly used to determine if a redirect was followed
- `info()` — return the meta-information of the page, such as headers, in the form of an *email.message_from_string()* instance (see Quick Reference to HTTP Headers)
- `getcode()` – return the HTTP status code of the response.

For HTTP and HTTPS URLs, this function returns a *http.client.HTTPResponse* object slightly modified. In addition to the three new methods above, the msg attribute contains the same information as the *reason* attribute — the reason phrase returned by server — instead of the response headers as it is specified in the documentation for *HTTPResponse*.

For FTP, file, and data URLs and requests explicitly handled by legacy *URLopener* and *FancyURLopener* classes, this function returns a `urllib.response.addinfourl` object.

Raises *URLError* on protocol errors.

Note that `None` may be returned if no handler handles the request (though the default installed global *OpenerDirector* uses *UnknownHandler* to ensure this never happens).

In addition, if proxy settings are detected (for example, when a `*_proxy` environment variable like `http_proxy` is set), *ProxyHandler* is default installed and makes sure the requests are handled through the proxy.

The legacy `urllib.urlopen` function from Python 2.6 and earlier has been discontinued; *urllib.request.urlopen()* corresponds to the old `urllib2.urlopen`. Proxy handling, which was done by passing a dictionary parameter to `urllib.urlopen`, can be obtained by using *ProxyHandler* objects.

Changed in version 3.2: *cafile* and *capath* were added.

Changed in version 3.2: HTTPS virtual hosts are now supported if possible (that is, if *ssl.HAS_SNI* is true).

New in version 3.2: *data* can be an iterable object.

Changed in version 3.3: *cadefault* was added.

Changed in version 3.4.3: *context* was added.

Deprecated since version 3.6: *cafile*, *capath* and *cadefault* are deprecated in favor of *context*. Please use *ssl.SSLContext.load_cert_chain()* instead, or let *ssl.create_default_context()* select the system's trusted CA certificates for you.

`urllib.request.install_opener(`*opener*`)`
Install an *OpenerDirector* instance as the default global opener. Installing an opener is only necessary if you want urlopen to use that opener; otherwise, simply call *OpenerDirector.open()* instead of *urlopen()*. The code does not check for a real *OpenerDirector*, and any class with the appropriate interface will work.

`urllib.request.build_opener(`[*handler*, ...]`)`
Return an *OpenerDirector* instance, which chains the handlers in the order given. *handler*s can be either instances of *BaseHandler*, or subclasses of *BaseHandler* (in which case it must be possible to call the constructor without any parameters). Instances of the following classes will be in front of the *handler*s, unless the *handler*s contain them, instances of them or subclasses of them: *ProxyHandler* (if proxy settings are detected), *UnknownHandler*, *HTTPHandler*, *HTTPDefaultErrorHandler*, *HTTPRedirectHandler*, *FTPHandler*, *FileHandler*, *HTTPErrorProcessor*.

If the Python installation has SSL support (i.e., if the *ssl* module can be imported), *HTTPSHandler* will also be added.

A *BaseHandler* subclass may also change its `handler_order` attribute to modify its position in the handlers list.

`urllib.request.pathname2url(`*path*`)`
Convert the pathname *path* from the local syntax for a path to the form used in the path component of a URL. This does not produce a complete URL. The return value will already be quoted using the *quote()* function.

`urllib.request.url2pathname(`*path*`)`
Convert the path component *path* from a percent-encoded URL to the local syntax for a path. This does not accept a complete URL. This function uses *unquote()* to decode *path*.

`urllib.request.getproxies()`
This helper function returns a dictionary of scheme to proxy server URL mappings. It scans the environment for variables named `<scheme>_proxy`, in a case insensitive approach, for all operating systems first, and when it cannot find it, looks for proxy information from Mac OSX System Configuration for Mac OS X and Windows Systems Registry for Windows. If both lowercase and uppercase environment variables exist (and disagree), lowercase is preferred.

Note: If the environment variable `REQUEST_METHOD` is set, which usually indicates your script is running in a CGI environment, the environment variable `HTTP_PROXY` (uppercase `_PROXY`) will be ignored. This is because that variable can be injected by a client using the "Proxy:" HTTP header. If you need to use an HTTP proxy in a CGI environment, either use `ProxyHandler` explicitly, or make sure the variable name is in lowercase (or at least the `_proxy` suffix).

The following classes are provided:

class urllib.request.Request(*url*, *data=None*, *headers={}*, *origin_req_host=None*, *unverifiable=False*, *method=None*)

This class is an abstraction of a URL request.

url should be a string containing a valid URL.

data must be an object specifying additional data to send to the server, or `None` if no such data is needed. Currently HTTP requests are the only ones that use *data*. The supported object types include bytes, file-like objects, and iterables. If no `Content-Length` nor `Transfer-Encoding` header field has been provided, *HTTPHandler* will set these headers according to the type of *data*. `Content-Length` will be used to send bytes objects, while `Transfer-Encoding: chunked` as specified in **RFC 7230**, Section 3.3.1 will be used to send files and other iterables.

For an HTTP POST request method, *data* should be a buffer in the standard *application/x-www-form-urlencoded* format. The *urllib.parse.urlencode()* function takes a mapping or sequence of 2-tuples and returns an ASCII string in this format. It should be encoded to bytes before being used as the *data* parameter.

headers should be a dictionary, and will be treated as if *add_header()* was called with each key and value as arguments. This is often used to "spoof" the `User-Agent` header value, which is used by a browser to identify itself – some HTTP servers only allow requests coming from common browsers as opposed to scripts. For example, Mozilla Firefox may identify itself as `"Mozilla/5.0 (X11; U; Linux i686) Gecko/20071127 Firefox/2.0.0.11"`, while *urllib*'s default user agent string is `"Python-urllib/2.6"` (on Python 2.6).

An appropriate `Content-Type` header should be included if the *data* argument is present. If this header has not been provided and *data* is not None, `Content-Type: application/x-www-form-urlencoded` will be added as a default.

The final two arguments are only of interest for correct handling of third-party HTTP cookies:

origin_req_host should be the request-host of the origin transaction, as defined by **RFC 2965**. It defaults to `http.cookiejar.request_host(self)`. This is the host name or IP address of the original request that was initiated by the user. For example, if the request is for an image in an HTML document, this should be the request-host of the request for the page containing the image.

unverifiable should indicate whether the request is unverifiable, as defined by **RFC 2965**. It defaults to `False`. An unverifiable request is one whose URL the user did not have the option to approve. For example, if the request is for an image in an HTML document, and the user had no option to approve the automatic fetching of the image, this should be true.

method should be a string that indicates the HTTP request method that will be used (e.g. `'HEAD'`). If provided, its value is stored in the *method* attribute and is used by *get_method()*. The default is `'GET'` if *data* is `None` or `'POST'` otherwise. Subclasses may indicate a different default method by setting the *method* attribute in the class itself.

Note: The request will not work as expected if the data object is unable to deliver its content more than once (e.g. a file or an iterable that can produce the content only once) and the request is retried for HTTP redirects or authentication. The *data* is sent to the HTTP server right away after the headers. There is no support for a 100-continue expectation in the library.

Changed in version 3.3: *Request.method* argument is added to the Request class.

Changed in version 3.4: Default *Request.method* may be indicated at the class level.

Changed in version 3.6: Do not raise an error if the `Content-Length` has not been provided and *data* is neither `None` nor a bytes object. Fall back to use chunked transfer encoding instead.

class urllib.request.OpenerDirector
The *OpenerDirector* class opens URLs via *BaseHandler*s chained together. It manages the chaining of handlers, and recovery from errors.

class urllib.request.BaseHandler
This is the base class for all registered handlers — and handles only the simple mechanics of registration.

class urllib.request.HTTPDefaultErrorHandler
A class which defines a default handler for HTTP error responses; all responses are turned into *HTTPError* exceptions.

class urllib.request.HTTPRedirectHandler
A class to handle redirections.

class urllib.request.HTTPCookieProcessor(*cookiejar=None*)
A class to handle HTTP Cookies.

class urllib.request.ProxyHandler(*proxies=None*)
Cause requests to go through a proxy. If *proxies* is given, it must be a dictionary mapping protocol names to URLs of proxies. The default is to read the list of proxies from the environment variables `<protocol>_proxy`. If no proxy environment variables are set, then in a Windows environment proxy settings are obtained from the registry's Internet Settings section, and in a Mac OS X environment proxy information is retrieved from the OS X System Configuration Framework.

To disable autodetected proxy pass an empty dictionary.

The `no_proxy` environment variable can be used to specify hosts which shouldn't be reached via proxy; if set, it should be a comma-separated list of hostname suffixes, optionally with `:port` appended, for example `cern.ch,ncsa.uiuc.edu,some.host:8080`.

> **Note:** `HTTP_PROXY` will be ignored if a variable `REQUEST_METHOD` is set; see the documentation on *getproxies()*.

class urllib.request.HTTPPasswordMgr
Keep a database of `(realm, uri) -> (user, password)` mappings.

class urllib.request.HTTPPasswordMgrWithDefaultRealm
Keep a database of `(realm, uri) -> (user, password)` mappings. A realm of `None` is considered a catch-all realm, which is searched if no other realm fits.

class urllib.request.HTTPPasswordMgrWithPriorAuth
A variant of *HTTPPasswordMgrWithDefaultRealm* that also has a database of `uri -> is_authenticated` mappings. Can be used by a BasicAuth handler to determine when to send authentication credentials immediately instead of waiting for a `401` response first.

New in version 3.5.

class urllib.request.AbstractBasicAuthHandler(*password_mgr=None*)
This is a mixin class that helps with HTTP authentication, both to the remote host and to a proxy. *password_mgr*, if given, should be something that is compatible with *HTTPPasswordMgr*; refer to section *HTTPPasswordMgr Objects* for information on the interface that must be supported. If *passwd_mgr* also provides `is_authenticated` and `update_authenticated` methods (see *HTTPPasswordMgrWithPriorAuth Objects*), then the handler will use the `is_authenticated` result for a given URI to determine whether or not to send authentication credentials with the request. If `is_authenticated` returns `True` for the URI, credentials are sent. If `is_authenticated` is `False`, credentials are not sent, and then if a `401` response is received the request is re-sent with the authentication credentials. If authentication succeeds, `update_authenticated` is called to set `is_authenticated True` for the URI, so that subsequent requests to the URI or any of its super-URIs will automatically include the authentication credentials.

New in version 3.5: Added `is_authenticated` support.

class urllib.request.HTTPBasicAuthHandler(*password_mgr=None*)
Handle authentication with the remote host. *password_mgr*, if given, should be something that is compatible with *HTTPPasswordMgr*; refer to section *HTTPPasswordMgr Objects* for information on the interface that must be supported. HTTPBasicAuthHandler will raise a *ValueError* when presented with a wrong Authentication scheme.

class urllib.request.ProxyBasicAuthHandler(*password_mgr=None*)
Handle authentication with the proxy. *password_mgr*, if given, should be something that is compatible with *HTTPPasswordMgr*; refer to section *HTTPPasswordMgr Objects* for information on the interface that must be supported.

class urllib.request.AbstractDigestAuthHandler(*password_mgr=None*)
This is a mixin class that helps with HTTP authentication, both to the remote host and to a proxy. *password_mgr*, if given, should be something that is compatible with *HTTPPasswordMgr*; refer to section *HTTPPasswordMgr Objects* for information on the interface that must be supported.

class urllib.request.HTTPDigestAuthHandler(*password_mgr=None*)
Handle authentication with the remote host. *password_mgr*, if given, should be something that is compatible with *HTTPPasswordMgr*; refer to section *HTTPPasswordMgr Objects* for information on the interface that must be supported. When both Digest Authentication Handler and Basic Authentication Handler are both added, Digest Authentication is always tried first. If the Digest Authentication returns a 40x response again, it is sent to Basic Authentication handler to Handle. This Handler method will raise a *ValueError* when presented with an authentication scheme other than Digest or Basic.

Changed in version 3.3: Raise *ValueError* on unsupported Authentication Scheme.

class urllib.request.ProxyDigestAuthHandler(*password_mgr=None*)
Handle authentication with the proxy. *password_mgr*, if given, should be something that is compatible with *HTTPPasswordMgr*; refer to section *HTTPPasswordMgr Objects* for information on the interface that must be supported.

class urllib.request.HTTPHandler
A class to handle opening of HTTP URLs.

class urllib.request.HTTPSHandler(*debuglevel=0*, *context=None*, *check_hostname=None*)
A class to handle opening of HTTPS URLs. *context* and *check_hostname* have the same meaning as in *http.client.HTTPSConnection*.

Changed in version 3.2: *context* and *check_hostname* were added.

class urllib.request.FileHandler
Open local files.

class urllib.request.DataHandler
Open data URLs.

New in version 3.4.

class urllib.request.FTPHandler
Open FTP URLs.

class urllib.request.CacheFTPHandler
Open FTP URLs, keeping a cache of open FTP connections to minimize delays.

class urllib.request.UnknownHandler
A catch-all class to handle unknown URLs.

class urllib.request.HTTPErrorProcessor
Process HTTP error responses.

22.6.1 Request Objects

The following methods describe *Request*'s public interface, and so all may be overridden in subclasses. It also defines several public attributes that can be used by clients to inspect the parsed request.

Request.full_url
The original URL passed to the constructor.

Changed in version 3.4.

Request.full_url is a property with setter, getter and a deleter. Getting *full_url* returns the original request URL with the fragment, if it was present.

Request.type
The URI scheme.

Request.host
The URI authority, typically a host, but may also contain a port separated by a colon.

Request.origin_req_host
The original host for the request, without port.

Request.selector
The URI path. If the *Request* uses a proxy, then selector will be the full URL that is passed to the proxy.

Request.data
The entity body for the request, or None if not specified.

Changed in version 3.4: Changing value of *Request.data* now deletes "Content-Length" header if it was previously set or calculated.

Request.unverifiable
boolean, indicates whether the request is unverifiable as defined by **RFC 2965**.

Request.method
The HTTP request method to use. By default its value is *None*, which means that *get_method()* will do its normal computation of the method to be used. Its value can be set (thus overriding the default computation in *get_method()*) either by providing a default value by setting it at the class level in a *Request* subclass, or by passing a value in to the *Request* constructor via the *method* argument.

New in version 3.3.

Changed in version 3.4: A default value can now be set in subclasses; previously it could only be set via the constructor argument.

Request.get_method()
Return a string indicating the HTTP request method. If *Request.method* is not None, return its value, otherwise return 'GET' if *Request.data* is None, or 'POST' if it's not. This is only meaningful for HTTP requests.

Changed in version 3.3: get_method now looks at the value of *Request.method*.

Request.add_header(*key*, *val*)
Add another header to the request. Headers are currently ignored by all handlers except HTTP handlers, where they are added to the list of headers sent to the server. Note that there cannot be more than one header with the same name, and later calls will overwrite previous calls in case the *key* collides. Currently, this is no loss of HTTP functionality, since all headers which have meaning when used more than once have a (header-specific) way of gaining the same functionality using only one header.

Request.add_unredirected_header(*key*, *header*)
Add a header that will not be added to a redirected request.

Request.**has_header**(*header*)
Return whether the instance has the named header (checks both regular and unredirected).

Request.**remove_header**(*header*)
Remove named header from the request instance (both from regular and unredirected headers).

New in version 3.4.

Request.**get_full_url**()
Return the URL given in the constructor.

Changed in version 3.4.

Returns *Request.full_url*

Request.**set_proxy**(*host*, *type*)
Prepare the request by connecting to a proxy server. The *host* and *type* will replace those of the instance, and the instance's selector will be the original URL given in the constructor.

Request.**get_header**(*header_name*, *default=None*)
Return the value of the given header. If the header is not present, return the default value.

Request.**header_items**()
Return a list of tuples (header_name, header_value) of the Request headers.

Changed in version 3.4: The request methods add_data, has_data, get_data, get_type, get_host, get_selector, get_origin_req_host and is_unverifiable that were deprecated since 3.3 have been removed.

22.6.2 OpenerDirector Objects

OpenerDirector instances have the following methods:

OpenerDirector.**add_handler**(*handler*)
handler should be an instance of *BaseHandler*. The following methods are searched, and added to the possible chains (note that HTTP errors are a special case).

- `protocol_open()` — signal that the handler knows how to open *protocol* URLs.
- `http_error_type()` — signal that the handler knows how to handle HTTP errors with HTTP error code *type*.
- `protocol_error()` — signal that the handler knows how to handle errors from (non-`http`) *protocol*.
- `protocol_request()` — signal that the handler knows how to pre-process *protocol* requests.
- `protocol_response()` — signal that the handler knows how to post-process *protocol* responses.

OpenerDirector.**open**(*url*, *data=None*[, *timeout*])
Open the given *url* (which can be a request object or a string), optionally passing the given *data*. Arguments, return values and exceptions raised are the same as those of *urlopen()* (which simply calls the *open()* method on the currently installed global *OpenerDirector*). The optional *timeout* parameter specifies a timeout in seconds for blocking operations like the connection attempt (if not specified, the global default timeout setting will be used). The timeout feature actually works only for HTTP, HTTPS and FTP connections).

OpenerDirector.**error**(*proto*, **args*)
Handle an error of the given protocol. This will call the registered error handlers for the given protocol with the given arguments (which are protocol specific). The HTTP protocol is a special case which uses the HTTP response code to determine the specific error handler; refer to the `http_error_*()` methods of the handler classes.

Return values and exceptions raised are the same as those of *urlopen()*.

OpenerDirector objects open URLs in three stages:

The order in which these methods are called within each stage is determined by sorting the handler instances.

1. Every handler with a method named like `protocol_request()` has that method called to pre-process the request.
2. Handlers with a method named like `protocol_open()` are called to handle the request. This stage ends when a handler either returns a non-*None* value (ie. a response), or raises an exception (usually *URLError*). Exceptions are allowed to propagate.

   In fact, the above algorithm is first tried for methods named `default_open()`. If all such methods return *None*, the algorithm is repeated for methods named like `protocol_open()`. If all such methods return *None*, the algorithm is repeated for methods named `unknown_open()`.

   Note that the implementation of these methods may involve calls of the parent *OpenerDirector* instance's *open()* and *error()* methods.
3. Every handler with a method named like `protocol_response()` has that method called to post-process the response.

22.6.3 BaseHandler Objects

BaseHandler objects provide a couple of methods that are directly useful, and others that are meant to be used by derived classes. These are intended for direct use:

`BaseHandler.add_parent(`*director*`)`
Add a director as parent.

`BaseHandler.close()`
Remove any parents.

The following attribute and methods should only be used by classes derived from *BaseHandler*.

Note: The convention has been adopted that subclasses defining `protocol_request()` or `protocol_response()` methods are named `*Processor`; all others are named `*Handler`.

`BaseHandler.parent`
A valid *OpenerDirector*, which can be used to open using a different protocol, or handle errors.

`BaseHandler.default_open(`*req*`)`
This method is *not* defined in *BaseHandler*, but subclasses should define it if they want to catch all URLs.

This method, if implemented, will be called by the parent *OpenerDirector*. It should return a file-like object as described in the return value of the *open()* of *OpenerDirector*, or `None`. It should raise *URLError*, unless a truly exceptional thing happens (for example, *MemoryError* should not be mapped to `URLError`).

This method will be called before any protocol-specific open method.

`BaseHandler.protocol_open(`*req*`)`
This method is *not* defined in *BaseHandler*, but subclasses should define it if they want to handle URLs with the given protocol.

This method, if defined, will be called by the parent *OpenerDirector*. Return values should be the same as for *default_open()*.

`BaseHandler.unknown_open(`*req*`)`
This method is *not* defined in *BaseHandler*, but subclasses should define it if they want to catch all URLs with no specific registered handler to open it.

This method, if implemented, will be called by the *parent* *OpenerDirector*. Return values should be the same as for *default_open()*.

`BaseHandler.http_error_default`(*req*, *fp*, *code*, *msg*, *hdrs*)
This method is *not* defined in *BaseHandler*, but subclasses should override it if they intend to provide a catch-all for otherwise unhandled HTTP errors. It will be called automatically by the *OpenerDirector* getting the error, and should not normally be called in other circumstances.

req will be a *Request* object, *fp* will be a file-like object with the HTTP error body, *code* will be the three-digit code of the error, *msg* will be the user-visible explanation of the code and *hdrs* will be a mapping object with the headers of the error.

Return values and exceptions raised should be the same as those of *urlopen()*.

`BaseHandler.http_error_nnn`(*req*, *fp*, *code*, *msg*, *hdrs*)
nnn should be a three-digit HTTP error code. This method is also not defined in *BaseHandler*, but will be called, if it exists, on an instance of a subclass, when an HTTP error with code *nnn* occurs.

Subclasses should override this method to handle specific HTTP errors.

Arguments, return values and exceptions raised should be the same as for *http_error_default()*.

`BaseHandler.protocol_request`(*req*)
This method is *not* defined in *BaseHandler*, but subclasses should define it if they want to pre-process requests of the given protocol.

This method, if defined, will be called by the parent *OpenerDirector*. *req* will be a *Request* object. The return value should be a *Request* object.

`BaseHandler.protocol_response`(*req*, *response*)
This method is *not* defined in *BaseHandler*, but subclasses should define it if they want to post-process responses of the given protocol.

This method, if defined, will be called by the parent *OpenerDirector*. *req* will be a *Request* object. *response* will be an object implementing the same interface as the return value of *urlopen()*. The return value should implement the same interface as the return value of *urlopen()*.

22.6.4 HTTPRedirectHandler Objects

Note: Some HTTP redirections require action from this module's client code. If this is the case, *HTTPError* is raised. See **RFC 2616** for details of the precise meanings of the various redirection codes.

An `HTTPError` exception raised as a security consideration if the HTTPRedirectHandler is presented with a redirected URL which is not an HTTP, HTTPS or FTP URL.

`HTTPRedirectHandler.redirect_request`(*req*, *fp*, *code*, *msg*, *hdrs*, *newurl*)
Return a *Request* or `None` in response to a redirect. This is called by the default implementations of the `http_error_30*()` methods when a redirection is received from the server. If a redirection should take place, return a new *Request* to allow `http_error_30*()` to perform the redirect to *newurl*. Otherwise, raise *HTTPError* if no other handler should try to handle this URL, or return `None` if you can't but another handler might.

Note: The default implementation of this method does not strictly follow **RFC 2616**, which says that 301 and 302 responses to `POST` requests must not be automatically redirected without confirmation by the user. In reality, browsers do allow automatic redirection of these responses, changing the POST to a `GET`, and the default implementation reproduces this behavior.

HTTPRedirectHandler.**http_error_301**(*req*, *fp*, *code*, *msg*, *hdrs*)
Redirect to the `Location:` or `URI:` URL. This method is called by the parent *OpenerDirector* when getting an HTTP 'moved permanently' response.

HTTPRedirectHandler.**http_error_302**(*req*, *fp*, *code*, *msg*, *hdrs*)
The same as *http_error_301()*, but called for the 'found' response.

HTTPRedirectHandler.**http_error_303**(*req*, *fp*, *code*, *msg*, *hdrs*)
The same as *http_error_301()*, but called for the 'see other' response.

HTTPRedirectHandler.**http_error_307**(*req*, *fp*, *code*, *msg*, *hdrs*)
The same as *http_error_301()*, but called for the 'temporary redirect' response.

22.6.5 HTTPCookieProcessor Objects

HTTPCookieProcessor instances have one attribute:

HTTPCookieProcessor.**cookiejar**
The *http.cookiejar.CookieJar* in which cookies are stored.

22.6.6 ProxyHandler Objects

ProxyHandler.**protocol_open**(*request*)
The *ProxyHandler* will have a method `protocol_open()` for every *protocol* which has a proxy in the *proxies* dictionary given in the constructor. The method will modify requests to go through the proxy, by calling `request.set_proxy()`, and call the next handler in the chain to actually execute the protocol.

22.6.7 HTTPPasswordMgr Objects

These methods are available on *HTTPPasswordMgr* and *HTTPPasswordMgrWithDefaultRealm* objects.

HTTPPasswordMgr.**add_password**(*realm*, *uri*, *user*, *passwd*)
uri can be either a single URI, or a sequence of URIs. *realm*, *user* and *passwd* must be strings. This causes `(user, passwd)` to be used as authentication tokens when authentication for *realm* and a super-URI of any of the given URIs is given.

HTTPPasswordMgr.**find_user_password**(*realm*, *authuri*)
Get user/password for given realm and URI, if any. This method will return `(None, None)` if there is no matching user/password.

For *HTTPPasswordMgrWithDefaultRealm* objects, the realm `None` will be searched if the given *realm* has no matching user/password.

22.6.8 HTTPPasswordMgrWithPriorAuth Objects

This password manager extends *HTTPPasswordMgrWithDefaultRealm* to support tracking URIs for which authentication credentials should always be sent.

HTTPPasswordMgrWithPriorAuth.**add_password**(*realm*, *uri*, *user*, *passwd*, *is_authenticated=False*)
realm, *uri*, *user*, *passwd* are as for *HTTPPasswordMgr.add_password()*. *is_authenticated* sets the initial value of the `is_authenticated` flag for the given URI or list of URIs. If *is_authenticated* is specified as `True`, *realm* is ignored.

HTTPPasswordMgr.**find_user_password**(*realm*, *authuri*)
Same as for *HTTPPasswordMgrWithDefaultRealm* objects

HTTPPasswordMgrWithPriorAuth.**update_authenticated**(*self*, *uri*, *is_authenticated=False*)
Update the `is_authenticated` flag for the given *uri* or list of URIs.

HTTPPasswordMgrWithPriorAuth.**is_authenticated**(*self*, *authuri*)
Returns the current state of the `is_authenticated` flag for the given URI.

22.6.9 AbstractBasicAuthHandler Objects

AbstractBasicAuthHandler.**http_error_auth_reqed**(*authreq*, *host*, *req*, *headers*)
Handle an authentication request by getting a user/password pair, and re-trying the request. *authreq* should be the name of the header where the information about the realm is included in the request, *host* specifies the URL and path to authenticate for, *req* should be the (failed) *Request* object, and *headers* should be the error headers.

host is either an authority (e.g. `"python.org"`) or a URL containing an authority component (e.g. `"http://python.org/"`). In either case, the authority must not contain a userinfo component (so, `"python.org"` and `"python.org:80"` are fine, `"joe:password@python.org"` is not).

22.6.10 HTTPBasicAuthHandler Objects

HTTPBasicAuthHandler.**http_error_401**(*req*, *fp*, *code*, *msg*, *hdrs*)
Retry the request with authentication information, if available.

22.6.11 ProxyBasicAuthHandler Objects

ProxyBasicAuthHandler.**http_error_407**(*req*, *fp*, *code*, *msg*, *hdrs*)
Retry the request with authentication information, if available.

22.6.12 AbstractDigestAuthHandler Objects

AbstractDigestAuthHandler.**http_error_auth_reqed**(*authreq*, *host*, *req*, *headers*)
authreq should be the name of the header where the information about the realm is included in the request, *host* should be the host to authenticate to, *req* should be the (failed) *Request* object, and *headers* should be the error headers.

22.6.13 HTTPDigestAuthHandler Objects

HTTPDigestAuthHandler.**http_error_401**(*req*, *fp*, *code*, *msg*, *hdrs*)
Retry the request with authentication information, if available.

22.6.14 ProxyDigestAuthHandler Objects

ProxyDigestAuthHandler.**http_error_407**(*req*, *fp*, *code*, *msg*, *hdrs*)
Retry the request with authentication information, if available.

22.6.15 HTTPHandler Objects

HTTPHandler.**http_open**(*req*)
Send an HTTP request, which can be either GET or POST, depending on `req.has_data()`.

22.6.16 HTTPSHandler Objects

`HTTPSHandler.https_open(req)`
Send an HTTPS request, which can be either GET or POST, depending on `req.has_data()`.

22.6.17 FileHandler Objects

`FileHandler.file_open(req)`
Open the file locally, if there is no host name, or the host name is `'localhost'`.

Changed in version 3.2: This method is applicable only for local hostnames. When a remote hostname is given, an *URLError* is raised.

22.6.18 DataHandler Objects

`DataHandler.data_open(req)`
Read a data URL. This kind of URL contains the content encoded in the URL itself. The data URL syntax is specified in **RFC 2397**. This implementation ignores white spaces in base64 encoded data URLs so the URL may be wrapped in whatever source file it comes from. But even though some browsers don't mind about a missing padding at the end of a base64 encoded data URL, this implementation will raise an *ValueError* in that case.

22.6.19 FTPHandler Objects

`FTPHandler.ftp_open(req)`
Open the FTP file indicated by *req*. The login is always done with empty username and password.

22.6.20 CacheFTPHandler Objects

CacheFTPHandler objects are *FTPHandler* objects with the following additional methods:

`CacheFTPHandler.setTimeout(t)`
Set timeout of connections to *t* seconds.

`CacheFTPHandler.setMaxConns(m)`
Set maximum number of cached connections to *m*.

22.6.21 UnknownHandler Objects

`UnknownHandler.unknown_open()`
Raise a *URLError* exception.

22.6.22 HTTPErrorProcessor Objects

`HTTPErrorProcessor.http_response()`
Process HTTP error responses.

For 200 error codes, the response object is returned immediately.

For non-200 error codes, this simply passes the job on to the `protocol_error_code()` handler methods, via *OpenerDirector.error()*. Eventually, *HTTPDefaultErrorHandler* will raise an *HTTPError* if no other handler handles the error.

HTTPErrorProcessor.**https_response**()
Process HTTPS error responses.

The behavior is same as *http_response()*.

22.6.23 Examples

In addition to the examples below, more examples are given in urllib-howto.

This example gets the python.org main page and displays the first 300 bytes of it.

```
>>> import urllib.request
>>> with urllib.request.urlopen('http://www.python.org/') as f:
...     print(f.read(300))
...
b'<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0 Transitional//EN"
"http://www.w3.org/TR/xhtml1/DTD/xhtml1-transitional.dtd">\n\n\n<html
xmlns="http://www.w3.org/1999/xhtml" xml:lang="en" lang="en">\n\n<head>\n
<meta http-equiv="content-type" content="text/html; charset=utf-8" />\n
<title>Python Programming '
```

Note that urlopen returns a bytes object. This is because there is no way for urlopen to automatically determine the encoding of the byte stream it receives from the HTTP server. In general, a program will decode the returned bytes object to string once it determines or guesses the appropriate encoding.

The following W3C document, https://www.w3.org/International/O-charset, lists the various ways in which an (X)HTML or an XML document could have specified its encoding information.

As the python.org website uses *utf-8* encoding as specified in its meta tag, we will use the same for decoding the bytes object.

```
>>> with urllib.request.urlopen('http://www.python.org/') as f:
...     print(f.read(100).decode('utf-8'))
...
<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0 Transitional//EN"
"http://www.w3.org/TR/xhtml1/DTD/xhtm
```

It is also possible to achieve the same result without using the *context manager* approach.

```
>>> import urllib.request
>>> f = urllib.request.urlopen('http://www.python.org/')
>>> print(f.read(100).decode('utf-8'))
<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0 Transitional//EN"
"http://www.w3.org/TR/xhtml1/DTD/xhtm
```

In the following example, we are sending a data-stream to the stdin of a CGI and reading the data it returns to us. Note that this example will only work when the Python installation supports SSL.

```
>>> import urllib.request
>>> req = urllib.request.Request(url='https://localhost/cgi-bin/test.cgi',
...                       data=b'This data is passed to stdin of the CGI')
>>> with urllib.request.urlopen(req) as f:
...     print(f.read().decode('utf-8'))
...
Got Data: "This data is passed to stdin of the CGI"
```

The code for the sample CGI used in the above example is:

```
#!/usr/bin/env python
import sys
data = sys.stdin.read()
print('Content-type: text/plain\n\nGot Data: "%s"' % data)
```

Here is an example of doing a PUT request using *Request*:

```
import urllib.request
DATA = b'some data'
req = urllib.request.Request(url='http://localhost:8080', data=DATA,method='PUT')
with urllib.request.urlopen(req) as f:
    pass
print(f.status)
print(f.reason)
```

Use of Basic HTTP Authentication:

```
import urllib.request
# Create an OpenerDirector with support for Basic HTTP Authentication...
auth_handler = urllib.request.HTTPBasicAuthHandler()
auth_handler.add_password(realm='PDQ Application',
                          uri='https://mahler:8092/site-updates.py',
                          user='klem',
                          passwd='kadidd!ehopper')
opener = urllib.request.build_opener(auth_handler)
# ...and install it globally so it can be used with urlopen.
urllib.request.install_opener(opener)
urllib.request.urlopen('http://www.example.com/login.html')
```

build_opener() provides many handlers by default, including a *ProxyHandler*. By default, *ProxyHandler* uses the environment variables named <scheme>_proxy, where <scheme> is the URL scheme involved. For example, the http_proxy environment variable is read to obtain the HTTP proxy's URL.

This example replaces the default *ProxyHandler* with one that uses programmatically-supplied proxy URLs, and adds proxy authorization support with *ProxyBasicAuthHandler*.

```
proxy_handler = urllib.request.ProxyHandler({'http': 'http://www.example.com:3128/'})
proxy_auth_handler = urllib.request.ProxyBasicAuthHandler()
proxy_auth_handler.add_password('realm', 'host', 'username', 'password')

opener = urllib.request.build_opener(proxy_handler, proxy_auth_handler)
# This time, rather than install the OpenerDirector, we use it directly:
opener.open('http://www.example.com/login.html')
```

Adding HTTP headers:

Use the *headers* argument to the *Request* constructor, or:

```
import urllib.request
req = urllib.request.Request('http://www.example.com/')
req.add_header('Referer', 'http://www.python.org/')
# Customize the default User-Agent header value:
req.add_header('User-Agent', 'urllib-example/0.1 (Contact: . . .)')
r = urllib.request.urlopen(req)
```

OpenerDirector automatically adds a *User-Agent* header to every *Request*. To change this:

```
import urllib.request
opener = urllib.request.build_opener()
opener.addheaders = [('User-agent', 'Mozilla/5.0')]
opener.open('http://www.example.com/')
```

Also, remember that a few standard headers (*Content-Length*, *Content-Type* and *Host*) are added when the *Request* is passed to *urlopen()* (or *OpenerDirector.open()*).

Here is an example session that uses the `GET` method to retrieve a URL containing parameters:

```
>>> import urllib.request
>>> import urllib.parse
>>> params = urllib.parse.urlencode({'spam': 1, 'eggs': 2, 'bacon': 0})
>>> url = "http://www.musi-cal.com/cgi-bin/query?%s" % params
>>> with urllib.request.urlopen(url) as f:
...     print(f.read().decode('utf-8'))
...
```

The following example uses the `POST` method instead. Note that params output from urlencode is encoded to bytes before it is sent to urlopen as data:

```
>>> import urllib.request
>>> import urllib.parse
>>> data = urllib.parse.urlencode({'spam': 1, 'eggs': 2, 'bacon': 0})
>>> data = data.encode('ascii')
>>> with urllib.request.urlopen("http://requestb.in/xrbl82xr", data) as f:
...     print(f.read().decode('utf-8'))
...
```

The following example uses an explicitly specified HTTP proxy, overriding environment settings:

```
>>> import urllib.request
>>> proxies = {'http': 'http://proxy.example.com:8080/'}
>>> opener = urllib.request.FancyURLopener(proxies)
>>> with opener.open("http://www.python.org") as f:
...     f.read().decode('utf-8')
...
```

The following example uses no proxies at all, overriding environment settings:

```
>>> import urllib.request
>>> opener = urllib.request.FancyURLopener({})
>>> with opener.open("http://www.python.org/") as f:
...     f.read().decode('utf-8')
...
```

22.6.24 Legacy interface

The following functions and classes are ported from the Python 2 module `urllib` (as opposed to `urllib2`). They might become deprecated at some point in the future.

`urllib.request.urlretrieve`(*url*, *filename=None*, *reporthook=None*, *data=None*)

Copy a network object denoted by a URL to a local file. If the URL points to a local file, the object will not be copied unless filename is supplied. Return a tuple `(filename, headers)` where *filename* is the local file name under which the object can be found, and *headers* is whatever the `info()` method of the object returned by *urlopen()* returned (for a remote object). Exceptions are the same as for *urlopen()*.

The second argument, if present, specifies the file location to copy to (if absent, the location will be a tempfile with a generated name). The third argument, if present, is a callable that will be called once on establishment of the network connection and once after each block read thereafter. The callable will be passed three arguments; a count of blocks transferred so far, a block size in bytes, and the total size of the file. The third argument may be `-1` on older FTP servers which do not return a file size in response to a retrieval request.

The following example illustrates the most common usage scenario:

```
>>> import urllib.request
>>> local_filename, headers = urllib.request.urlretrieve('http://python.org/')
>>> html = open(local_filename)
>>> html.close()
```

If the *url* uses the `http:` scheme identifier, the optional *data* argument may be given to specify a `POST` request (normally the request type is `GET`). The *data* argument must be a bytes object in standard *application/x-www-form-urlencoded* format; see the *urllib.parse.urlencode()* function.

urlretrieve() will raise `ContentTooShortError` when it detects that the amount of data available was less than the expected amount (which is the size reported by a *Content-Length* header). This can occur, for example, when the download is interrupted.

The *Content-Length* is treated as a lower bound: if there's more data to read, urlretrieve reads more data, but if less data is available, it raises the exception.

You can still retrieve the downloaded data in this case, it is stored in the `content` attribute of the exception instance.

If no *Content-Length* header was supplied, urlretrieve can not check the size of the data it has downloaded, and just returns it. In this case you just have to assume that the download was successful.

`urllib.request.urlcleanup()`
Cleans up temporary files that may have been left behind by previous calls to *urlretrieve()*.

`class urllib.request.URLopener(`*proxies=None*, ***x509*`)`
Deprecated since version 3.3.

Base class for opening and reading URLs. Unless you need to support opening objects using schemes other than `http:`, `ftp:`, or `file:`, you probably want to use *FancyURLopener*.

By default, the *URLopener* class sends a *User-Agent* header of `urllib/VVV`, where *VVV* is the *urllib* version number. Applications can define their own *User-Agent* header by subclassing *URLopener* or *FancyURLopener* and setting the class attribute *version* to an appropriate string value in the subclass definition.

The optional *proxies* parameter should be a dictionary mapping scheme names to proxy URLs, where an empty dictionary turns proxies off completely. Its default value is `None`, in which case environmental proxy settings will be used if present, as discussed in the definition of *urlopen()*, above.

Additional keyword parameters, collected in *x509*, may be used for authentication of the client when using the `https:` scheme. The keywords *key_file* and *cert_file* are supported to provide an SSL key and certificate; both are needed to support client authentication.

URLopener objects will raise an *OSError* exception if the server returns an error code.

`open(`*fullurl*, *data=None*`)`
Open *fullurl* using the appropriate protocol. This method sets up cache and proxy information, then calls the appropriate open method with its input arguments. If the scheme is not recognized, *open_unknown()* is called. The *data* argument has the same meaning as the *data* argument of *urlopen()*.

`open_unknown(`*fullurl*, *data=None*`)`
Overridable interface to open unknown URL types.

retrieve(*url*, *filename=None*, *reporthook=None*, *data=None*)
Retrieves the contents of *url* and places it in *filename*. The return value is a tuple consisting of a local filename and either an *email.message.Message* object containing the response headers (for remote URLs) or `None` (for local URLs). The caller must then open and read the contents of *filename*. If *filename* is not given and the URL refers to a local file, the input filename is returned. If the URL is non-local and *filename* is not given, the filename is the output of *tempfile.mktemp()* with a suffix that matches the suffix of the last path component of the input URL. If *reporthook* is given, it must be a function accepting three numeric parameters: A chunk number, the maximum size chunks are read in and the total size of the download (-1 if unknown). It will be called once at the start and after each chunk of data is read from the network. *reporthook* is ignored for local URLs.

If the *url* uses the `http:` scheme identifier, the optional *data* argument may be given to specify a `POST` request (normally the request type is `GET`). The *data* argument must in standard *application/x-www-form-urlencoded* format; see the *urllib.parse.urlencode()* function.

version
Variable that specifies the user agent of the opener object. To get *urllib* to tell servers that it is a particular user agent, set this in a subclass as a class variable or in the constructor before calling the base constructor.

class urllib.request.FancyURLopener(...)
Deprecated since version 3.3.

FancyURLopener subclasses *URLopener* providing default handling for the following HTTP response codes: 301, 302, 303, 307 and 401. For the 30x response codes listed above, the *Location* header is used to fetch the actual URL. For 401 response codes (authentication required), basic HTTP authentication is performed. For the 30x response codes, recursion is bounded by the value of the *maxtries* attribute, which defaults to 10.

For all other response codes, the method `http_error_default()` is called which you can override in subclasses to handle the error appropriately.

Note: According to the letter of **RFC 2616**, 301 and 302 responses to POST requests must not be automatically redirected without confirmation by the user. In reality, browsers do allow automatic redirection of these responses, changing the POST to a GET, and *urllib* reproduces this behaviour.

The parameters to the constructor are the same as those for *URLopener*.

Note: When performing basic authentication, a *FancyURLopener* instance calls its *prompt_user_passwd()* method. The default implementation asks the users for the required information on the controlling terminal. A subclass may override this method to support more appropriate behavior if needed.

The *FancyURLopener* class offers one additional method that should be overloaded to provide the appropriate behavior:

prompt_user_passwd(*host*, *realm*)
Return information needed to authenticate the user at the given host in the specified security realm. The return value should be a tuple, `(user, password)`, which can be used for basic authentication.

The implementation prompts for this information on the terminal; an application should override this method to use an appropriate interaction model in the local environment.

22.6.25 urllib.request Restrictions

- Currently, only the following protocols are supported: HTTP (versions 0.9 and 1.0), FTP, local files, and data URLs.

  Changed in version 3.4: Added support for data URLs.
- The caching feature of *urlretrieve()* has been disabled until someone finds the time to hack proper processing of Expiration time headers.
- There should be a function to query whether a particular URL is in the cache.
- For backward compatibility, if a URL appears to point to a local file but the file can't be opened, the URL is re-interpreted using the FTP protocol. This can sometimes cause confusing error messages.
- The *urlopen()* and *urlretrieve()* functions can cause arbitrarily long delays while waiting for a network connection to be set up. This means that it is difficult to build an interactive Web client using these functions without using threads.
- The data returned by *urlopen()* or *urlretrieve()* is the raw data returned by the server. This may be binary data (such as an image), plain text or (for example) HTML. The HTTP protocol provides type information in the reply header, which can be inspected by looking at the *Content-Type* header. If the returned data is HTML, you can use the module *html.parser* to parse it.
- The code handling the FTP protocol cannot differentiate between a file and a directory. This can lead to unexpected behavior when attempting to read a URL that points to a file that is not accessible. If the URL ends in a `/`, it is assumed to refer to a directory and will be handled accordingly. But if an attempt to read a file leads to a 550 error (meaning the URL cannot be found or is not accessible, often for permission reasons), then the path is treated as a directory in order to handle the case when a directory is specified by a URL but the trailing `/` has been left off. This can cause misleading results when you try to fetch a file whose read permissions make it inaccessible; the FTP code will try to read it, fail with a 550 error, and then perform a directory listing for the unreadable file. If fine-grained control is needed, consider using the *ftplib* module, subclassing *FancyURLopener*, or changing *_urlopener* to meet your needs.

22.7 urllib.response — Response classes used by urllib

The *urllib.response* module defines functions and classes which define a minimal file like interface, including `read()` and `readline()`. The typical response object is an addinfourl instance, which defines an `info()` method and that returns headers and a `geturl()` method that returns the url. Functions defined by this module are used internally by the *urllib.request* module.

22.8 urllib.parse — Parse URLs into components

Source code: Lib/urllib/parse.py

This module defines a standard interface to break Uniform Resource Locator (URL) strings up in components (addressing scheme, network location, path etc.), to combine the components back into a URL string, and to convert a "relative URL" to an absolute URL given a "base URL."

The module has been designed to match the Internet RFC on Relative Uniform Resource Locators. It supports the following URL schemes: `file`, `ftp`, `gopher`, `hdl`, `http`, `https`, `imap`, `mailto`, `mms`, `news`, `nntp`, `prospero`, `rsync`, `rtsp`, `rtspu`, `sftp`, `shttp`, `sip`, `sips`, `snews`, `svn`, `svn+ssh`, `telnet`, `wais`, `ws`, `wss`.

The *urllib.parse* module defines functions that fall into two broad categories: URL parsing and URL quoting. These are covered in detail in the following sections.

22.8.1 URL Parsing

The URL parsing functions focus on splitting a URL string into its components, or on combining URL components into a URL string.

urllib.parse.urlparse(*urlstring*, *scheme=''*, *allow_fragments=True*)

Parse a URL into six components, returning a 6-tuple. This corresponds to the general structure of a URL: `scheme://netloc/path;parameters?query#fragment`. Each tuple item is a string, possibly empty. The components are not broken up in smaller parts (for example, the network location is a single string), and % escapes are not expanded. The delimiters as shown above are not part of the result, except for a leading slash in the *path* component, which is retained if present. For example:

```
>>> from urllib.parse import urlparse
>>> o = urlparse('http://www.cwi.nl:80/%7Eguido/Python.html')
>>> o
ParseResult(scheme='http', netloc='www.cwi.nl:80', path='/%7Eguido/Python.html',
            params='', query='', fragment='')
>>> o.scheme
'http'
>>> o.port
80
>>> o.geturl()
'http://www.cwi.nl:80/%7Eguido/Python.html'
```

Following the syntax specifications in **RFC 1808**, urlparse recognizes a netloc only if it is properly introduced by '//'. Otherwise the input is presumed to be a relative URL and thus to start with a path component.

```
>>> from urllib.parse import urlparse
>>> urlparse('//www.cwi.nl:80/%7Eguido/Python.html')
ParseResult(scheme='', netloc='www.cwi.nl:80', path='/%7Eguido/Python.html',
            params='', query='', fragment='')
>>> urlparse('www.cwi.nl/%7Eguido/Python.html')
ParseResult(scheme='', netloc='', path='www.cwi.nl/%7Eguido/Python.html',
            params='', query='', fragment='')
>>> urlparse('help/Python.html')
ParseResult(scheme='', netloc='', path='help/Python.html', params='',
            query='', fragment='')
```

The *scheme* argument gives the default addressing scheme, to be used only if the URL does not specify one. It should be the same type (text or bytes) as *urlstring*, except that the default value `''` is always allowed, and is automatically converted to `b''` if appropriate.

If the *allow_fragments* argument is false, fragment identifiers are not recognized. Instead, they are parsed as part of the path, parameters or query component, and `fragment` is set to the empty string in the return value.

The return value is actually an instance of a subclass of *tuple*. This class has the following additional read-only convenience attributes:

Attribute	Index	Value	Value if not present
`scheme`	0	URL scheme specifier	*scheme* parameter
`netloc`	1	Network location part	empty string
`path`	2	Hierarchical path	empty string
`params`	3	Parameters for last path element	empty string
`query`	4	Query component	empty string
`fragment`	5	Fragment identifier	empty string
`username`		User name	*None*
`password`		Password	*None*
`hostname`		Host name (lower case)	*None*
`port`		Port number as integer, if present	*None*

Reading the `port` attribute will raise a *ValueError* if an invalid port is specified in the URL. See section *Structured Parse Results* for more information on the result object.

Unmatched square brackets in the `netloc` attribute will raise a *ValueError*.

Changed in version 3.2: Added IPv6 URL parsing capabilities.

Changed in version 3.3: The fragment is now parsed for all URL schemes (unless *allow_fragment* is false), in accordance with **RFC 3986**. Previously, a whitelist of schemes that support fragments existed.

Changed in version 3.6: Out-of-range port numbers now raise *ValueError*, instead of returning *None*.

`urllib.parse.parse_qs`(*qs*, *keep_blank_values=False*, *strict_parsing=False*, *encoding='utf-8'*, *errors='replace'*)

Parse a query string given as a string argument (data of type *application/x-www-form-urlencoded*). Data are returned as a dictionary. The dictionary keys are the unique query variable names and the values are lists of values for each name.

The optional argument *keep_blank_values* is a flag indicating whether blank values in percent-encoded queries should be treated as blank strings. A true value indicates that blanks should be retained as blank strings. The default false value indicates that blank values are to be ignored and treated as if they were not included.

The optional argument *strict_parsing* is a flag indicating what to do with parsing errors. If false (the default), errors are silently ignored. If true, errors raise a *ValueError* exception.

The optional *encoding* and *errors* parameters specify how to decode percent-encoded sequences into Unicode characters, as accepted by the *bytes.decode()* method.

Use the *urllib.parse.urlencode()* function (with the `doseq` parameter set to `True`) to convert such dictionaries into query strings.

Changed in version 3.2: Add *encoding* and *errors* parameters.

`urllib.parse.parse_qsl`(*qs*, *keep_blank_values=False*, *strict_parsing=False*, *encoding='utf-8'*, *errors='replace'*)

Parse a query string given as a string argument (data of type *application/x-www-form-urlencoded*). Data are returned as a list of name, value pairs.

The optional argument *keep_blank_values* is a flag indicating whether blank values in percent-encoded queries should be treated as blank strings. A true value indicates that blanks should be retained as blank strings. The default false value indicates that blank values are to be ignored and treated as if they were not included.

The optional argument *strict_parsing* is a flag indicating what to do with parsing errors. If false (the default), errors are silently ignored. If true, errors raise a *ValueError* exception.

The optional *encoding* and *errors* parameters specify how to decode percent-encoded sequences into Unicode characters, as accepted by the *bytes.decode()* method.

Use the *urllib.parse.urlencode()* function to convert such lists of pairs into query strings.

Changed in version 3.2: Add *encoding* and *errors* parameters.

urllib.parse.urlunparse(*parts*)
Construct a URL from a tuple as returned by `urlparse()`. The *parts* argument can be any six-item iterable. This may result in a slightly different, but equivalent URL, if the URL that was parsed originally had unnecessary delimiters (for example, a `?` with an empty query; the RFC states that these are equivalent).

urllib.parse.urlsplit(*urlstring*, *scheme=''*, *allow_fragments=True*)
This is similar to *urlparse()*, but does not split the params from the URL. This should generally be used instead of *urlparse()* if the more recent URL syntax allowing parameters to be applied to each segment of the *path* portion of the URL (see **RFC 2396**) is wanted. A separate function is needed to separate the path segments and parameters. This function returns a 5-tuple: (addressing scheme, network location, path, query, fragment identifier).

The return value is actually an instance of a subclass of *tuple*. This class has the following additional read-only convenience attributes:

Attribute	Index	Value	Value if not present
`scheme`	0	URL scheme specifier	*scheme* parameter
`netloc`	1	Network location part	empty string
`path`	2	Hierarchical path	empty string
`query`	3	Query component	empty string
`fragment`	4	Fragment identifier	empty string
`username`		User name	*None*
`password`		Password	*None*
`hostname`		Host name (lower case)	*None*
`port`		Port number as integer, if present	*None*

Reading the `port` attribute will raise a *ValueError* if an invalid port is specified in the URL. See section *Structured Parse Results* for more information on the result object.

Unmatched square brackets in the `netloc` attribute will raise a *ValueError*.

Changed in version 3.6: Out-of-range port numbers now raise *ValueError*, instead of returning *None*.

urllib.parse.urlunsplit(*parts*)
Combine the elements of a tuple as returned by *urlsplit()* into a complete URL as a string. The *parts* argument can be any five-item iterable. This may result in a slightly different, but equivalent URL, if the URL that was parsed originally had unnecessary delimiters (for example, a ? with an empty query; the RFC states that these are equivalent).

urllib.parse.urljoin(*base*, *url*, *allow_fragments=True*)
Construct a full ("absolute") URL by combining a "base URL" (*base*) with another URL (*url*). Informally, this uses components of the base URL, in particular the addressing scheme, the network location and (part of) the path, to provide missing components in the relative URL. For example:

```
>>> from urllib.parse import urljoin
>>> urljoin('http://www.cwi.nl/%7Eguido/Python.html', 'FAQ.html')
'http://www.cwi.nl/%7Eguido/FAQ.html'
```

The *allow_fragments* argument has the same meaning and default as for *urlparse()*.

Note: If *url* is an absolute URL (that is, starting with `//` or `scheme://`), the *url*'s host name and/or scheme will be present in the result. For example:

```
>>> urljoin('http://www.cwi.nl/%7Eguido/Python.html',
...         '//www.python.org/%7Eguido')
'http://www.python.org/%7Eguido'
```

If you do not want that behavior, preprocess the *url* with *urlsplit()* and *urlunsplit()*, removing possible *scheme* and *netloc* parts.

Changed in version 3.5: Behaviour updated to match the semantics defined in **RFC 3986**.

`urllib.parse.urldefrag(`*url*`)`

If *url* contains a fragment identifier, return a modified version of *url* with no fragment identifier, and the fragment identifier as a separate string. If there is no fragment identifier in *url*, return *url* unmodified and an empty string.

The return value is actually an instance of a subclass of *tuple*. This class has the following additional read-only convenience attributes:

Attribute	Index	Value	Value if not present
`url`	0	URL with no fragment	empty string
`fragment`	1	Fragment identifier	empty string

See section *Structured Parse Results* for more information on the result object.

Changed in version 3.2: Result is a structured object rather than a simple 2-tuple.

22.8.2 Parsing ASCII Encoded Bytes

The URL parsing functions were originally designed to operate on character strings only. In practice, it is useful to be able to manipulate properly quoted and encoded URLs as sequences of ASCII bytes. Accordingly, the URL parsing functions in this module all operate on *bytes* and *bytearray* objects in addition to *str* objects.

If *str* data is passed in, the result will also contain only *str* data. If *bytes* or *bytearray* data is passed in, the result will contain only *bytes* data.

Attempting to mix *str* data with *bytes* or *bytearray* in a single function call will result in a *TypeError* being raised, while attempting to pass in non-ASCII byte values will trigger *UnicodeDecodeError*.

To support easier conversion of result objects between *str* and *bytes*, all return values from URL parsing functions provide either an `encode()` method (when the result contains *str* data) or a `decode()` method (when the result contains *bytes* data). The signatures of these methods match those of the corresponding *str* and *bytes* methods (except that the default encoding is `'ascii'` rather than `'utf-8'`). Each produces a value of a corresponding type that contains either *bytes* data (for `encode()` methods) or *str* data (for `decode()` methods).

Applications that need to operate on potentially improperly quoted URLs that may contain non-ASCII data will need to do their own decoding from bytes to characters before invoking the URL parsing methods.

The behaviour described in this section applies only to the URL parsing functions. The URL quoting functions use their own rules when producing or consuming byte sequences as detailed in the documentation of the individual URL quoting functions.

Changed in version 3.2: URL parsing functions now accept ASCII encoded byte sequences

22.8.3 Structured Parse Results

The result objects from the *urlparse()*, *urlsplit()* and *urldefrag()* functions are subclasses of the *tuple* type. These subclasses add the attributes listed in the documentation for those functions, the encoding and decoding support described in the previous section, as well as an additional method:

urllib.parse.SplitResult.geturl()

Return the re-combined version of the original URL as a string. This may differ from the original URL in that the scheme may be normalized to lower case and empty components may be dropped. Specifically, empty parameters, queries, and fragment identifiers will be removed.

For *urldefrag()* results, only empty fragment identifiers will be removed. For *urlsplit()* and *urlparse()* results, all noted changes will be made to the URL returned by this method.

The result of this method remains unchanged if passed back through the original parsing function:

```
>>> from urllib.parse import urlsplit
>>> url = 'HTTP://www.Python.org/doc/#'
>>> r1 = urlsplit(url)
>>> r1.geturl()
'http://www.Python.org/doc/'
>>> r2 = urlsplit(r1.geturl())
>>> r2.geturl()
'http://www.Python.org/doc/'
```

The following classes provide the implementations of the structured parse results when operating on *str* objects:

class urllib.parse.DefragResult(*url*, *fragment*)

Concrete class for *urldefrag()* results containing *str* data. The `encode()` method returns a *DefragResultBytes* instance.

New in version 3.2.

class urllib.parse.ParseResult(*scheme*, *netloc*, *path*, *params*, *query*, *fragment*)

Concrete class for *urlparse()* results containing *str* data. The `encode()` method returns a *ParseResultBytes* instance.

class urllib.parse.SplitResult(*scheme*, *netloc*, *path*, *query*, *fragment*)

Concrete class for *urlsplit()* results containing *str* data. The `encode()` method returns a *SplitResultBytes* instance.

The following classes provide the implementations of the parse results when operating on *bytes* or *bytearray* objects:

class urllib.parse.DefragResultBytes(*url*, *fragment*)

Concrete class for *urldefrag()* results containing *bytes* data. The `decode()` method returns a *DefragResult* instance.

New in version 3.2.

class urllib.parse.ParseResultBytes(*scheme*, *netloc*, *path*, *params*, *query*, *fragment*)

Concrete class for *urlparse()* results containing *bytes* data. The `decode()` method returns a *ParseResult* instance.

New in version 3.2.

class urllib.parse.SplitResultBytes(*scheme*, *netloc*, *path*, *query*, *fragment*)

Concrete class for *urlsplit()* results containing *bytes* data. The `decode()` method returns a *SplitResult* instance.

New in version 3.2.

22.8.4 URL Quoting

The URL quoting functions focus on taking program data and making it safe for use as URL components by quoting special characters and appropriately encoding non-ASCII text. They also support reversing these operations to recreate the original data from the contents of a URL component if that task isn't already covered by the URL parsing functions above.

`urllib.parse.quote`(*string*, *safe='/'*, *encoding=None*, *errors=None*)
Replace special characters in *string* using the `%xx` escape. Letters, digits, and the characters `'_.-~'` are never quoted. By default, this function is intended for quoting the path section of URL. The optional *safe* parameter specifies additional ASCII characters that should not be quoted — its default value is `'/'`.

string may be either a *str* or a *bytes*.

Changed in version 3.7: Moved from **RFC 2396** to **RFC 3986** for quoting URL strings. "~" is now included in the set of reserved characters.

The optional *encoding* and *errors* parameters specify how to deal with non-ASCII characters, as accepted by the *str.encode()* method. *encoding* defaults to `'utf-8'`. *errors* defaults to `'strict'`, meaning unsupported characters raise a *UnicodeEncodeError*. *encoding* and *errors* must not be supplied if *string* is a *bytes*, or a *TypeError* is raised.

Note that `quote(string, safe, encoding, errors)` is equivalent to `quote_from_bytes(string.encode(encoding, errors), safe)`.

Example: `quote('/El Niño/')` yields `'/El%20Ni%C3%B1o/'`.

`urllib.parse.quote_plus`(*string*, *safe=''*, *encoding=None*, *errors=None*)
Like *quote()*, but also replace spaces by plus signs, as required for quoting HTML form values when building up a query string to go into a URL. Plus signs in the original string are escaped unless they are included in *safe*. It also does not have *safe* default to `'/'`.

Example: `quote_plus('/El Niño/')` yields `'%2FEl+Ni%C3%B1o%2F'`.

`urllib.parse.quote_from_bytes`(*bytes*, *safe='/'*)
Like *quote()*, but accepts a *bytes* object rather than a *str*, and does not perform string-to-bytes encoding.

Example: `quote_from_bytes(b'a&\xef')` yields `'a%26%EF'`.

`urllib.parse.unquote`(*string*, *encoding='utf-8'*, *errors='replace'*)
Replace `%xx` escapes by their single-character equivalent. The optional *encoding* and *errors* parameters specify how to decode percent-encoded sequences into Unicode characters, as accepted by the *bytes.decode()* method.

string must be a *str*.

encoding defaults to `'utf-8'`. *errors* defaults to `'replace'`, meaning invalid sequences are replaced by a placeholder character.

Example: `unquote('/El%20Ni%C3%B1o/')` yields `'/El Niño/'`.

`urllib.parse.unquote_plus`(*string*, *encoding='utf-8'*, *errors='replace'*)
Like *unquote()*, but also replace plus signs by spaces, as required for unquoting HTML form values.

string must be a *str*.

Example: `unquote_plus('/El+Ni%C3%B1o/')` yields `'/El Niño/'`.

`urllib.parse.unquote_to_bytes`(*string*)
Replace `%xx` escapes by their single-octet equivalent, and return a *bytes* object.

string may be either a *str* or a *bytes*.

If it is a *str*, unescaped non-ASCII characters in *string* are encoded into UTF-8 bytes.

Example: `unquote_to_bytes('a%26%EF')` yields `b'a&\xef'`.

`urllib.parse.urlencode`(*query*, *doseq=False*, *safe=''*, *encoding=None*, *errors=None*, *quote_via=quote_plus*)

Convert a mapping object or a sequence of two-element tuples, which may contain *str* or *bytes* objects, to a percent-encoded ASCII text string. If the resultant string is to be used as a *data* for POST operation with the *urlopen()* function, then it should be encoded to bytes, otherwise it would result in a *TypeError*.

The resulting string is a series of `key=value` pairs separated by `'&'` characters, where both *key* and *value* are quoted using the *quote_via* function. By default, *quote_plus()* is used to quote the values, which means spaces are quoted as a `'+'` character and '/' characters are encoded as `%2F`, which follows the standard for GET requests (`application/x-www-form-urlencoded`). An alternate function that can be passed as *quote_via* is *quote()*, which will encode spaces as `%20` and not encode '/' characters. For maximum control of what is quoted, use `quote` and specify a value for *safe*.

When a sequence of two-element tuples is used as the *query* argument, the first element of each tuple is a key and the second is a value. The value element in itself can be a sequence and in that case, if the optional parameter *doseq* is evaluates to `True`, individual `key=value` pairs separated by `'&'` are generated for each element of the value sequence for the key. The order of parameters in the encoded string will match the order of parameter tuples in the sequence.

The *safe*, *encoding*, and *errors* parameters are passed down to *quote_via* (the *encoding* and *errors* parameters are only passed when a query element is a *str*).

To reverse this encoding process, *parse_qs()* and *parse_qsl()* are provided in this module to parse query strings into Python data structures.

Refer to *urllib examples* to find out how urlencode method can be used for generating query string for a URL or data for POST.

Changed in version 3.2: Query parameter supports bytes and string objects.

New in version 3.5: *quote_via* parameter.

RFC 3986 - Uniform Resource Identifiers This is the current standard (STD66). Any changes to urllib.parse module should conform to this. Certain deviations could be observed, which are mostly for backward compatibility purposes and for certain de-facto parsing requirements as commonly observed in major browsers.

RFC 2732 - Format for Literal IPv6 Addresses in URL's. This specifies the parsing requirements of IPv6 URLs.

RFC 2396 - Uniform Resource Identifiers (URI): Generic Syntax Document describing the generic syntactic requirements for both Uniform Resource Names (URNs) and Uniform Resource Locators (URLs).

RFC 2368 - The mailto URL scheme. Parsing requirements for mailto URL schemes.

RFC 1808 - Relative Uniform Resource Locators This Request For Comments includes the rules for joining an absolute and a relative URL, including a fair number of "Abnormal Examples" which govern the treatment of border cases.

RFC 1738 - Uniform Resource Locators (URL) This specifies the formal syntax and semantics of absolute URLs.

22.9 `urllib.error` — Exception classes raised by urllib.request

Source code: Lib/urllib/error.py

The *urllib.error* module defines the exception classes for exceptions raised by *urllib.request*. The base exception class is *URLError*.

The following exceptions are raised by *urllib.error* as appropriate:

exception urllib.error.URLError
The handlers raise this exception (or derived exceptions) when they run into a problem. It is a subclass of *OSError*.

reason
The reason for this error. It can be a message string or another exception instance.

Changed in version 3.3: *URLError* has been made a subclass of *OSError* instead of *IOError*.

exception urllib.error.HTTPError
Though being an exception (a subclass of *URLError*), an *HTTPError* can also function as a non-exceptional file-like return value (the same thing that *urlopen()* returns). This is useful when handling exotic HTTP errors, such as requests for authentication.

code
An HTTP status code as defined in **RFC 2616**. This numeric value corresponds to a value found in the dictionary of codes as found in *http.server.BaseHTTPRequestHandler.responses*.

reason
This is usually a string explaining the reason for this error.

headers
The HTTP response headers for the HTTP request that caused the *HTTPError*.

New in version 3.4.

exception urllib.error.ContentTooShortError(*msg*, *content***)**
This exception is raised when the *urlretrieve()* function detects that the amount of the downloaded data is less than the expected amount (given by the *Content-Length* header). The `content` attribute stores the downloaded (and supposedly truncated) data.

22.10 `urllib.robotparser` — Parser for robots.txt

Source code: Lib/urllib/robotparser.py

This module provides a single class, *RobotFileParser*, which answers questions about whether or not a particular user agent can fetch a URL on the Web site that published the `robots.txt` file. For more details on the structure of `robots.txt` files, see http://www.robotstxt.org/orig.html.

class urllib.robotparser.RobotFileParser(*url=''***)**
This class provides methods to read, parse and answer questions about the `robots.txt` file at *url*.

set_url(*url***)**
Sets the URL referring to a `robots.txt` file.

read()
Reads the `robots.txt` URL and feeds it to the parser.

parse(*lines***)**
Parses the lines argument.

can_fetch(*useragent*, *url*)
Returns `True` if the *useragent* is allowed to fetch the *url* according to the rules contained in the parsed `robots.txt` file.

mtime()
Returns the time the `robots.txt` file was last fetched. This is useful for long-running web spiders that need to check for new `robots.txt` files periodically.

modified()
Sets the time the `robots.txt` file was last fetched to the current time.

crawl_delay(*useragent*)
Returns the value of the `Crawl-delay` parameter from `robots.txt` for the *useragent* in question. If there is no such parameter or it doesn't apply to the *useragent* specified or the `robots.txt` entry for this parameter has invalid syntax, return `None`.

New in version 3.6.

request_rate(*useragent*)
Returns the contents of the `Request-rate` parameter from `robots.txt` as a *named tuple* `RequestRate(requests, seconds)`. If there is no such parameter or it doesn't apply to the *useragent* specified or the `robots.txt` entry for this parameter has invalid syntax, return `None`.

New in version 3.6.

The following example demonstrates basic use of the *RobotFileParser* class:

```
>>> import urllib.robotparser
>>> rp = urllib.robotparser.RobotFileParser()
>>> rp.set_url("http://www.musi-cal.com/robots.txt")
>>> rp.read()
>>> rrate = rp.request_rate("*")
>>> rrate.requests
3
>>> rrate.seconds
20
>>> rp.crawl_delay("*")
6
>>> rp.can_fetch("*", "http://www.musi-cal.com/cgi-bin/search?city=San+Francisco")
False
>>> rp.can_fetch("*", "http://www.musi-cal.com/")
True
```

22.11 http — HTTP modules

Source code: Lib/http/__init__.py

---

http is a package that collects several modules for working with the HyperText Transfer Protocol:

- *http.client* is a low-level HTTP protocol client; for high-level URL opening use *urllib.request*
- *http.server* contains basic HTTP server classes based on *socketserver*
- *http.cookies* has utilities for implementing state management with cookies
- *http.cookiejar* provides persistence of cookies

http is also a module that defines a number of HTTP status codes and associated messages through the *http.HTTPStatus* enum:

class http.HTTPStatus

New in version 3.5.

A subclass of *enum.IntEnum* that defines a set of HTTP status codes, reason phrases and long descriptions written in English.

Usage:

```
>>> from http import HTTPStatus
>>> HTTPStatus.OK
<HTTPStatus.OK: 200>
>>> HTTPStatus.OK == 200
True
>>> http.HTTPStatus.OK.value
200
>>> HTTPStatus.OK.phrase
'OK'
>>> HTTPStatus.OK.description
'Request fulfilled, document follows'
>>> list(HTTPStatus)
[<HTTPStatus.CONTINUE: 100>, <HTTPStatus.SWITCHING_PROTOCOLS: 101>, ...]
```

22.11.1 HTTP status codes

Supported, IANA-registered status codes available in *http.HTTPStatus* are:

Code	Enum Name	Details
100	CONTINUE	HTTP/1.1 **RFC 7231**, Section 6.2.1
101	SWITCHING_PROTOCOLS	HTTP/1.1 **RFC 7231**, Section 6.2.2
102	PROCESSING	WebDAV **RFC 2518**, Section 10.1
200	OK	HTTP/1.1 **RFC 7231**, Section 6.3.1
201	CREATED	HTTP/1.1 **RFC 7231**, Section 6.3.2
202	ACCEPTED	HTTP/1.1 **RFC 7231**, Section 6.3.3
203	NON_AUTHORITATIVE_INFORMATION	HTTP/1.1 **RFC 7231**, Section 6.3.4
204	NO_CONTENT	HTTP/1.1 **RFC 7231**, Section 6.3.5
205	RESET_CONTENT	HTTP/1.1 **RFC 7231**, Section 6.3.6
206	PARTIAL_CONTENT	HTTP/1.1 **RFC 7233**, Section 4.1
207	MULTI_STATUS	WebDAV **RFC 4918**, Section 11.1
208	ALREADY_REPORTED	WebDAV Binding Extensions **RFC 5842**, Section 7.1 (Experimental)
226	IM_USED	Delta Encoding in HTTP **RFC 3229**, Section 10.4.1
300	MULTIPLE_CHOICES	HTTP/1.1 **RFC 7231**, Section 6.4.1
301	MOVED_PERMANENTLY	HTTP/1.1 **RFC 7231**, Section 6.4.2
302	FOUND	HTTP/1.1 **RFC 7231**, Section 6.4.3
303	SEE_OTHER	HTTP/1.1 **RFC 7231**, Section 6.4.4
304	NOT_MODIFIED	HTTP/1.1 **RFC 7232**, Section 4.1
305	USE_PROXY	HTTP/1.1 **RFC 7231**, Section 6.4.5
307	TEMPORARY_REDIRECT	HTTP/1.1 **RFC 7231**, Section 6.4.7
308	PERMANENT_REDIRECT	Permanent Redirect **RFC 7238**, Section 3 (Experimental)
400	BAD_REQUEST	HTTP/1.1 **RFC 7231**, Section 6.5.1
401	UNAUTHORIZED	HTTP/1.1 Authentication **RFC 7235**, Section 3.1
402	PAYMENT_REQUIRED	HTTP/1.1 **RFC 7231**, Section 6.5.2
403	FORBIDDEN	HTTP/1.1 **RFC 7231**, Section 6.5.3
404	NOT_FOUND	HTTP/1.1 **RFC 7231**, Section 6.5.4

Continued on

Table 1 – continued from previous page

Code	Enum Name	Details
405	METHOD_NOT_ALLOWED	HTTP/1.1 **RFC 7231**, Section 6.5.5
406	NOT_ACCEPTABLE	HTTP/1.1 **RFC 7231**, Section 6.5.6
407	PROXY_AUTHENTICATION_REQUIRED	HTTP/1.1 Authentication **RFC 7235**, Section 3.2

In order to preserve backwards compatibility, enum values are also present in the *http.client* module in the form of constants. The enum name is equal to the constant name (i.e. `http.HTTPStatus.OK` is also available as `http.client.OK`).

Changed in version 3.7: Added `421 MISDIRECTED_REQUEST` status code.

22.12 `http.client` — HTTP protocol client

Source code: Lib/http/client.py

This module defines classes which implement the client side of the HTTP and HTTPS protocols. It is normally not used directly — the module *urllib.request* uses it to handle URLs that use HTTP and HTTPS.

See also:

The Requests package is recommended for a higher-level HTTP client interface.

Note: HTTPS support is only available if Python was compiled with SSL support (through the *ssl* module).

The module provides the following classes:

class http.client.HTTPConnection(*host*, *port=None*[, *timeout*], *source_address=None*, *blocksize=8192*)

An *HTTPConnection* instance represents one transaction with an HTTP server. It should be instantiated passing it a host and optional port number. If no port number is passed, the port is extracted from the host string if it has the form `host:port`, else the default HTTP port (80) is used. If the optional *timeout* parameter is given, blocking operations (like connection attempts) will timeout after that many seconds (if it is not given, the global default timeout setting is used). The optional *source_address* parameter may be a tuple of a (host, port) to use as the source address the HTTP connection is made from. The optional *blocksize* parameter sets the buffer size in bytes for sending a file-like message body.

For example, the following calls all create instances that connect to the server at the same host and port:

```
>>> h1 = http.client.HTTPConnection('www.python.org')
>>> h2 = http.client.HTTPConnection('www.python.org:80')
>>> h3 = http.client.HTTPConnection('www.python.org', 80)
>>> h4 = http.client.HTTPConnection('www.python.org', 80, timeout=10)
```

Changed in version 3.2: *source_address* was added.

Changed in version 3.4: The *strict* parameter was removed. HTTP 0.9-style "Simple Responses" are not longer supported.

Changed in version 3.7: *blocksize* parameter was added.

class http.client.HTTPSConnection(*host*, *port=None*, *key_file=None*, *cert_file=None*[, *timeout*], *source_address=None*, ***, *context=None*, *check_hostname=None*, *blocksize=8192*)

A subclass of *HTTPConnection* that uses SSL for communication with secure servers. Default port is 443. If *context* is specified, it must be a *ssl.SSLContext* instance describing the various SSL options.

Please read *Security considerations* for more information on best practices.

Changed in version 3.2: *source_address*, *context* and *check_hostname* were added.

Changed in version 3.2: This class now supports HTTPS virtual hosts if possible (that is, if *ssl.HAS_SNI* is true).

Changed in version 3.4: The *strict* parameter was removed. HTTP 0.9-style "Simple Responses" are no longer supported.

Changed in version 3.4.3: This class now performs all the necessary certificate and hostname checks by default. To revert to the previous, unverified, behavior `ssl._create_unverified_context()` can be passed to the *context* parameter.

Deprecated since version 3.6: *key_file* and *cert_file* are deprecated in favor of *context*. Please use *ssl.SSLContext.load_cert_chain()* instead, or let *ssl.create_default_context()* select the system's trusted CA certificates for you.

The *check_hostname* parameter is also deprecated; the *ssl.SSLContext.check_hostname* attribute of *context* should be used instead.

class http.client.HTTPResponse(*sock*, *debuglevel=0*, *method=None*, *url=None*)

Class whose instances are returned upon successful connection. Not instantiated directly by user.

Changed in version 3.4: The *strict* parameter was removed. HTTP 0.9 style "Simple Responses" are no longer supported.

The following exceptions are raised as appropriate:

exception http.client.HTTPException
The base class of the other exceptions in this module. It is a subclass of *Exception*.

exception http.client.NotConnected
A subclass of *HTTPException*.

exception http.client.InvalidURL
A subclass of *HTTPException*, raised if a port is given and is either non-numeric or empty.

exception http.client.UnknownProtocol
A subclass of *HTTPException*.

exception http.client.UnknownTransferEncoding
A subclass of *HTTPException*.

exception http.client.UnimplementedFileMode
A subclass of *HTTPException*.

exception http.client.IncompleteRead
A subclass of *HTTPException*.

exception http.client.ImproperConnectionState
A subclass of *HTTPException*.

exception http.client.CannotSendRequest
A subclass of *ImproperConnectionState*.

exception http.client.CannotSendHeader
A subclass of *ImproperConnectionState*.

exception http.client.ResponseNotReady
A subclass of *ImproperConnectionState*.

exception http.client.BadStatusLine
A subclass of *HTTPException*. Raised if a server responds with a HTTP status code that we don't understand.

exception http.client.LineTooLong
A subclass of *HTTPException*. Raised if an excessively long line is received in the HTTP protocol from the server.

exception http.client.RemoteDisconnected
A subclass of *ConnectionResetError* and *BadStatusLine*. Raised by *HTTPConnection.getresponse()* when the attempt to read the response results in no data read from the connection, indicating that the remote end has closed the connection.

New in version 3.5: Previously, *BadStatusLine*`('')` was raised.

The constants defined in this module are:

http.client.HTTP_PORT
The default port for the HTTP protocol (always `80`).

http.client.HTTPS_PORT
The default port for the HTTPS protocol (always `443`).

http.client.responses
This dictionary maps the HTTP 1.1 status codes to the W3C names.

Example: `http.client.responses[http.client.NOT_FOUND]` is `'Not Found'`.

See *HTTP status codes* for a list of HTTP status codes that are available in this module as constants.

22.12.1 HTTPConnection Objects

HTTPConnection instances have the following methods:

HTTPConnection.**request**(*method*, *url*, *body=None*, *headers={}*, ***, *encode_chunked=False*)
This will send a request to the server using the HTTP request method *method* and the selector *url*.

If *body* is specified, the specified data is sent after the headers are finished. It may be a *str*, a *bytes-like object*, an open *file object*, or an iterable of *bytes*. If *body* is a string, it is encoded as ISO-8859-1, the default for HTTP. If it is a bytes-like object, the bytes are sent as is. If it is a *file object*, the contents of the file is sent; this file object should support at least the `read()` method. If the file object is an instance of *io.TextIOBase*, the data returned by the `read()` method will be encoded as ISO-8859-1, otherwise the data returned by `read()` is sent as is. If *body* is an iterable, the elements of the iterable are sent as is until the iterable is exhausted.

The *headers* argument should be a mapping of extra HTTP headers to send with the request.

If *headers* contains neither Content-Length nor Transfer-Encoding, but there is a request body, one of those header fields will be added automatically. If *body* is `None`, the Content-Length header is set to `0` for methods that expect a body (`PUT`, `POST`, and `PATCH`). If *body* is a string or a bytes-like object that is not also a *file*, the Content-Length header is set to its length. Any other type of *body* (files and iterables in general) will be chunk-encoded, and the Transfer-Encoding header will automatically be set instead of Content-Length.

The *encode_chunked* argument is only relevant if Transfer-Encoding is specified in *headers*. If *encode_chunked* is `False`, the HTTPConnection object assumes that all encoding is handled by the calling code. If it is `True`, the body will be chunk-encoded.

Note: Chunked transfer encoding has been added to the HTTP protocol version 1.1. Unless the HTTP server is known to handle HTTP 1.1, the caller must either specify the Content-Length, or must pass a *str* or bytes-like object that is not also a file as the body representation.

New in version 3.2: *body* can now be an iterable.

Changed in version 3.6: If neither Content-Length nor Transfer-Encoding are set in *headers*, file and iterable *body* objects are now chunk-encoded. The *encode_chunked* argument was added. No attempt is made to determine the Content-Length for file objects.

HTTPConnection.**getresponse**()
Should be called after a request is sent to get the response from the server. Returns an *HTTPResponse* instance.

Note: Note that you must have read the whole response before you can send a new request to the server.

Changed in version 3.5: If a *ConnectionError* or subclass is raised, the *HTTPConnection* object will be ready to reconnect when a new request is sent.

HTTPConnection.**set_debuglevel**(*level*)
Set the debugging level. The default debug level is `0`, meaning no debugging output is printed. Any value greater than `0` will cause all currently defined debug output to be printed to stdout. The `debuglevel` is passed to any new *HTTPResponse* objects that are created.

New in version 3.1.

HTTPConnection.**set_tunnel**(*host*, *port=None*, *headers=None*)
Set the host and the port for HTTP Connect Tunnelling. This allows running the connection through a proxy server.

The host and port arguments specify the endpoint of the tunneled connection (i.e. the address included in the CONNECT request, *not* the address of the proxy server).

The headers argument should be a mapping of extra HTTP headers to send with the CONNECT request.

For example, to tunnel through a HTTPS proxy server running locally on port 8080, we would pass the address of the proxy to the *HTTPSConnection* constructor, and the address of the host that we eventually want to reach to the *set_tunnel()* method:

```
>>> import http.client
>>> conn = http.client.HTTPSConnection("localhost", 8080)
>>> conn.set_tunnel("www.python.org")
>>> conn.request("HEAD","/index.html")
```

New in version 3.2.

HTTPConnection.connect()
Connect to the server specified when the object was created. By default, this is called automatically when making a request if the client does not already have a connection.

HTTPConnection.close()
Close the connection to the server.

HTTPConnection.blocksize
Buffer size in bytes for sending a file-like message body.

New in version 3.7.

As an alternative to using the `request()` method described above, you can also send your request step by step, by using the four functions below.

HTTPConnection.putrequest(*method*, *url*, *skip_host=False*, *skip_accept_encoding=False*)
This should be the first call after the connection to the server has been made. It sends a line to the server consisting of the *method* string, the *url* string, and the HTTP version (`HTTP/1.1`). To disable automatic sending of `Host:` or `Accept-Encoding:` headers (for example to accept additional content encodings), specify *skip_host* or *skip_accept_encoding* with non-False values.

HTTPConnection.putheader(*header*, *argument*[, ...])
Send an **RFC 822**-style header to the server. It sends a line to the server consisting of the header, a colon and a space, and the first argument. If more arguments are given, continuation lines are sent, each consisting of a tab and an argument.

HTTPConnection.endheaders(*message_body=None*, ***, *encode_chunked=False*)
Send a blank line to the server, signalling the end of the headers. The optional *message_body* argument can be used to pass a message body associated with the request.

If *encode_chunked* is `True`, the result of each iteration of *message_body* will be chunk-encoded as specified in **RFC 7230**, Section 3.3.1. How the data is encoded is dependent on the type of *message_body*. If *message_body* implements the buffer interface the encoding will result in a single chunk. If *message_body* is a *collections.abc.Iterable*, each iteration of *message_body* will result in a chunk. If *message_body* is a *file object*, each call to `.read()` will result in a chunk. The method automatically signals the end of the chunk-encoded data immediately after *message_body*.

Note: Due to the chunked encoding specification, empty chunks yielded by an iterator body will be ignored by the chunk-encoder. This is to avoid premature termination of the read of the request by the target server due to malformed encoding.

New in version 3.6: Chunked encoding support. The *encode_chunked* parameter was added.

HTTPConnection.**send**(*data*)
Send data to the server. This should be used directly only after the *endheaders()* method has been called and before *getresponse()* is called.

22.12.2 HTTPResponse Objects

An *HTTPResponse* instance wraps the HTTP response from the server. It provides access to the request headers and the entity body. The response is an iterable object and can be used in a with statement.

Changed in version 3.5: The *io.BufferedIOBase* interface is now implemented and all of its reader operations are supported.

HTTPResponse.**read**([*amt*])
Reads and returns the response body, or up to the next *amt* bytes.

HTTPResponse.**readinto**(*b*)
Reads up to the next len(b) bytes of the response body into the buffer *b*. Returns the number of bytes read.

New in version 3.3.

HTTPResponse.**getheader**(*name*, *default=None*)
Return the value of the header *name*, or *default* if there is no header matching *name*. If there is more than one header with the name *name*, return all of the values joined by ', '. If 'default' is any iterable other than a single string, its elements are similarly returned joined by commas.

HTTPResponse.**getheaders**()
Return a list of (header, value) tuples.

HTTPResponse.**fileno**()
Return the `fileno` of the underlying socket.

HTTPResponse.**msg**
A `http.client.HTTPMessage` instance containing the response headers. `http.client.HTTPMessage` is a subclass of *email.message.Message*.

HTTPResponse.**version**
HTTP protocol version used by server. 10 for HTTP/1.0, 11 for HTTP/1.1.

HTTPResponse.**status**
Status code returned by server.

HTTPResponse.**reason**
Reason phrase returned by server.

HTTPResponse.**debuglevel**
A debugging hook. If *debuglevel* is greater than zero, messages will be printed to stdout as the response is read and parsed.

HTTPResponse.**closed**
Is `True` if the stream is closed.

22.12.3 Examples

Here is an example session that uses the `GET` method:

```
>>> import http.client
>>> conn = http.client.HTTPSConnection("www.python.org")
>>> conn.request("GET", "/")
>>> r1 = conn.getresponse()
```

(continues on next page)

(continued from previous page)

```
>>> print(r1.status, r1.reason)
200 OK
>>> data1 = r1.read()  # This will return entire content.
>>> # The following example demonstrates reading data in chunks.
>>> conn.request("GET", "/")
>>> r1 = conn.getresponse()
>>> while not r1.closed:
...     print(r1.read(200))  # 200 bytes
b'<!doctype html>\n<!--[if"...
...
>>> # Example of an invalid request
>>> conn.request("GET", "/parrot.spam")
>>> r2 = conn.getresponse()
>>> print(r2.status, r2.reason)
404 Not Found
>>> data2 = r2.read()
>>> conn.close()
```

Here is an example session that uses the `HEAD` method. Note that the `HEAD` method never returns any data.

```
>>> import http.client
>>> conn = http.client.HTTPSConnection("www.python.org")
>>> conn.request("HEAD", "/")
>>> res = conn.getresponse()
>>> print(res.status, res.reason)
200 OK
>>> data = res.read()
>>> print(len(data))
0
>>> data == b''
True
```

Here is an example session that shows how to `POST` requests:

```
>>> import http.client, urllib.parse
>>> params = urllib.parse.urlencode({'@number': 12524, '@type': 'issue', '@action': 'show'})
>>> headers = {"Content-type": "application/x-www-form-urlencoded",
...            "Accept": "text/plain"}
>>> conn = http.client.HTTPConnection("bugs.python.org")
>>> conn.request("POST", "", params, headers)
>>> response = conn.getresponse()
>>> print(response.status, response.reason)
302 Found
>>> data = response.read()
>>> data
b'Redirecting to <a href="http://bugs.python.org/issue12524">http://bugs.python.org/issue12524</a>'
>>> conn.close()
```

Client side `HTTP PUT` requests are very similar to `POST` requests. The difference lies only the server side where HTTP server will allow resources to be created via `PUT` request. It should be noted that custom HTTP methods +are also handled in *`urllib.request.Request`* by sending the appropriate +method attribute.Here is an example session that shows how to do `PUT` request using http.client:

```
>>> # This creates an HTTP message
>>> # with the content of BODY as the enclosed representation
>>> # for the resource http://localhost:8080/file
```

(continues on next page)

(continued from previous page)

```
...
>>> import http.client
>>> BODY = "***filecontents***"
>>> conn = http.client.HTTPConnection("localhost", 8080)
>>> conn.request("PUT", "/file", BODY)
>>> response = conn.getresponse()
>>> print(response.status, response.reason)
200, OK
```

22.12.4 HTTPMessage Objects

An `http.client.HTTPMessage` instance holds the headers from an HTTP response. It is implemented using the *email.message.Message* class.

22.13 `ftplib` — FTP protocol client

Source code: Lib/ftplib.py

This module defines the class *FTP* and a few related items. The *FTP* class implements the client side of the FTP protocol. You can use this to write Python programs that perform a variety of automated FTP jobs, such as mirroring other FTP servers. It is also used by the module *urllib.request* to handle URLs that use FTP. For more information on FTP (File Transfer Protocol), see Internet **RFC 959**.

Here's a sample session using the *ftplib* module:

```
>>> from ftplib import FTP
>>> ftp = FTP('ftp.debian.org')     # connect to host, default port
>>> ftp.login()                     # user anonymous, passwd anonymous@
'230 Login successful.'
>>> ftp.cwd('debian')               # change into "debian" directory
>>> ftp.retrlines('LIST')           # list directory contents
-rw-rw-r--    1 1176     1176         1063 Jun 15 10:18 README
...
drwxr-sr-x    5 1176     1176         4096 Dec 19  2000 pool
drwxr-sr-x    4 1176     1176         4096 Nov 17  2008 project
drwxr-xr-x    3 1176     1176         4096 Oct 10  2012 tools
'226 Directory send OK.'
>>> ftp.retrbinary('RETR README', open('README', 'wb').write)
'226 Transfer complete.'
>>> ftp.quit()
```

The module defines the following items:

class ftplib.FTP(*host=''*, *user=''*, *passwd=''*, *acct=''*, *timeout=None*, *source_address=None*)

Return a new instance of the *FTP* class. When *host* is given, the method call `connect(host)` is made. When *user* is given, additionally the method call `login(user, passwd, acct)` is made (where *passwd* and *acct* default to the empty string when not given). The optional *timeout* parameter specifies a timeout in seconds for blocking operations like the connection attempt (if is not specified, the global default timeout setting will be used). *source_address* is a 2-tuple `(host, port)` for the socket to bind to as its source address before connecting.

The *FTP* class supports the `with` statement, e.g.:

```
>>> from ftplib import FTP
>>> with FTP("ftp1.at.proftpd.org") as ftp:
...     ftp.login()
...     ftp.dir()
...
'230 Anonymous login ok, restrictions apply.'
dr-xr-xr-x   9 ftp      ftp           154 May  6 10:43 .
dr-xr-xr-x   9 ftp      ftp           154 May  6 10:43 ..
dr-xr-xr-x   5 ftp      ftp          4096 May  6 10:43 CentOS
dr-xr-xr-x   3 ftp      ftp            18 Jul 10  2008 Fedora
>>>
```

Changed in version 3.2: Support for the `with` statement was added.

Changed in version 3.3: *source_address* parameter was added.

class ftplib.FTP_TLS(*host=''*, *user=''*, *passwd=''*, *acct=''*, *keyfile=None*, *certfile=None*, *context=None*, *timeout=None*, *source_address=None*)

A *FTP* subclass which adds TLS support to FTP as described in **RFC 4217**. Connect as usual to port 21 implicitly securing the FTP control connection before authenticating. Securing the data connection requires the user to explicitly ask for it by calling the *prot_p()* method. *context* is a *ssl.SSLContext* object which allows bundling SSL configuration options, certificates and private keys into a single (potentially long-lived) structure. Please read *Security considerations* for best practices.

keyfile and *certfile* are a legacy alternative to *context* – they can point to PEM-formatted private key and certificate chain files (respectively) for the SSL connection.

New in version 3.2.

Changed in version 3.3: *source_address* parameter was added.

Changed in version 3.4: The class now supports hostname check with *ssl.SSLContext.check_hostname* and *Server Name Indication* (see *ssl.HAS_SNI*).

Deprecated since version 3.6: *keyfile* and *certfile* are deprecated in favor of *context*. Please use *ssl.SSLContext.load_cert_chain()* instead, or let *ssl.create_default_context()* select the system's trusted CA certificates for you.

Here's a sample session using the *FTP_TLS* class:

```
>>> ftps = FTP_TLS('ftp.pureftpd.org')
>>> ftps.login()
'230 Anonymous user logged in'
>>> ftps.prot_p()
'200 Data protection level set to "private"'
>>> ftps.nlst()
['6jack', 'OpenBSD', 'antilink', 'blogbench', 'bsdcam', 'clockspeed', 'djbdns-jedi', 'docs',
↪'eaccelerator-jedi', 'favicon.ico', 'francotone', 'fugu', 'ignore', 'libpuzzle', 'metalog',
↪'minidentd', 'misc', 'mysql-udf-global-user-variables', 'php-jenkins-hash', 'php-skein-hash
↪', 'php-webdav', 'phpaudit', 'phpbench', 'pincaster', 'ping', 'posto', 'pub', 'public',
↪'public_keys', 'pure-ftpd', 'qscan', 'qtc', 'sharedance', 'skycache', 'sound', 'tmp', 'ucarp
↪']
```

exception ftplib.error_reply

Exception raised when an unexpected reply is received from the server.

exception ftplib.error_temp

Exception raised when an error code signifying a temporary error (response codes in the range 400–499) is received.

exception ftplib.error_perm

Exception raised when an error code signifying a permanent error (response codes in the range 500–599)

is received.

exception ftplib.error_proto
Exception raised when a reply is received from the server that does not fit the response specifications of the File Transfer Protocol, i.e. begin with a digit in the range 1–5.

ftplib.all_errors
The set of all exceptions (as a tuple) that methods of *FTP* instances may raise as a result of problems with the FTP connection (as opposed to programming errors made by the caller). This set includes the four exceptions listed above as well as *OSError*.

See also:

Module *netrc* Parser for the `.netrc` file format. The file `.netrc` is typically used by FTP clients to load user authentication information before prompting the user.

22.13.1 FTP Objects

Several methods are available in two flavors: one for handling text files and another for binary files. These are named for the command which is used followed by `lines` for the text version or `binary` for the binary version.

FTP instances have the following methods:

FTP.set_debuglevel(*level*)
Set the instance's debugging level. This controls the amount of debugging output printed. The default, `0`, produces no debugging output. A value of `1` produces a moderate amount of debugging output, generally a single line per request. A value of `2` or higher produces the maximum amount of debugging output, logging each line sent and received on the control connection.

FTP.connect(*host=''*, *port=0*, *timeout=None*, *source_address=None*)
Connect to the given host and port. The default port number is `21`, as specified by the FTP protocol specification. It is rarely needed to specify a different port number. This function should be called only once for each instance; it should not be called at all if a host was given when the instance was created. All other methods can only be used after a connection has been made. The optional *timeout* parameter specifies a timeout in seconds for the connection attempt. If no *timeout* is passed, the global default timeout setting will be used. *source_address* is a 2-tuple `(host, port)` for the socket to bind to as its source address before connecting.

Changed in version 3.3: *source_address* parameter was added.

FTP.getwelcome()
Return the welcome message sent by the server in reply to the initial connection. (This message sometimes contains disclaimers or help information that may be relevant to the user.)

FTP.login(*user='anonymous'*, *passwd=''*, *acct=''*)
